An eigenvalue $(\text{alphar}[j] + \text{alphai}[j])/\text{beta}[j]$ is selected if `select(alphar[j], alphai[j], beta[j])` is true; that is, if either one of a complex conjugate pair of eigenvalues is selected, then both complex eigenvalues are selected.

Note that in the ill-conditioned case, a selected complex eigenvalue may no longer satisfy `select(alphar[j], alphai[j], beta[j]) = 1` after ordering. In this case `info` is set to $n+2$.

For complex flavors:

An eigenvalue $\text{alpha}[j] / \text{beta}[j]$ is selected if `select(alpha[j], beta[j])` is true.

Note that a selected complex eigenvalue may no longer satisfy `select(alpha[j], beta[j]) = 1` after ordering, since ordering may change the value of complex eigenvalues (especially if the eigenvalue is ill-conditioned); in this case `info` is set to $n+2$ (see `info` below).

`sense`

Must be 'N', 'E', 'V', or 'B'. Determines which reciprocal condition number are computed.

If `sense = 'N'`, none are computed;

If `sense = 'E'`, computed for average of selected eigenvalues only;

If `sense = 'V'`, computed for selected deflating subspaces only;

If `sense = 'B'`, computed for both.

If `sense` is 'E', 'V', or 'B', then `sort` must equal 'S'.

`n`

The order of the matrices `A`, `B`, `vs1`, and `vsr` ($n \geq 0$).

`a`, `b`

Arrays:

`a` (size at least $\max(1, \text{lda} * n)$) is an array containing the n -by- n matrix `A` (first of the pair of matrices).

`b` (size at least $\max(1, \text{ldb} * n)$) is an array containing the n -by- n matrix `B` (second of the pair of matrices).

`lda`

The leading dimension of the array `a`.

Must be at least $\max(1, n)$.

`ldb`

The leading dimension of the array `b`.

Must be at least $\max(1, n)$.

`ldvs1`, `ldvsr`

The leading dimensions of the output matrices `vs1` and `vsr`, respectively. Constraints:

`ldvs1` ≥ 1 . If `jobvs1 = 'V'`, `ldvs1` $\geq \max(1, n)$.

`ldvsr` ≥ 1 . If `jobvsr = 'V'`, `ldvsr` $\geq \max(1, n)$.

Output Parameters

<i>a</i>	On exit, this array has been overwritten by its generalized Schur form <i>S</i> .
<i>b</i>	On exit, this array has been overwritten by its generalized Schur form <i>T</i> .
<i>sdim</i>	If <i>sort</i> = 'N', <i>sdim</i> = 0. If <i>sort</i> = 'S', <i>sdim</i> is equal to the number of eigenvalues (after sorting) for which <i>select</i> is true. Note that for real flavors complex conjugate pairs for which <i>select</i> is true for either eigenvalue count as 2.
<i>alphar</i> , <i>alphai</i>	Arrays, size at least $\max(1, n)$ each. Contain values that form generalized eigenvalues in real flavors. See <i>beta</i>.
<i>alpha</i>	Array, size at least $\max(1, n)$. Contain values that form generalized eigenvalues in complex flavors. See <i>beta</i> .
<i>beta</i>	Array, size at least $\max(1, n)$. For real flavors: On exit, $(\text{alphar}[j] + \text{alphai}[j]*i)/\text{beta}[j]$, $j=0, \dots, n-1$ will be the generalized eigenvalues. $\text{alphar}[j] + \text{alphai}[j]*i$ and $\text{beta}[j]$, $j=0, \dots, n-1$ are the diagonals of the complex Schur form (<i>S</i>,<i>T</i>) that would result if the 2-by-2 diagonal blocks of the real generalized Schur form of (<i>A</i>,<i>B</i>) were further reduced to triangular form using complex unitary transformations. If $\text{alphai}[j]$ is zero, then the <i>j</i>-th eigenvalue is real; if positive, then the <i>j</i>-th and (<i>j</i>+1)-st eigenvalues are a complex conjugate pair, with $\text{alphai}[j+1]$ negative. For complex flavors: On exit, $\text{alpha}[j]/\text{beta}[j]$, $j=0, \dots, n-1$ will be the generalized eigenvalues. $\text{alpha}[j]$ and $\text{beta}[j]$, $j=0, \dots, n-1$ are the diagonals of the complex Schur form (<i>S</i>,<i>T</i>) output by <i>cggesx/zggesx</i>. The $\text{beta}[j]$ will be non-negative real. See also <i>Application Notes</i> below.
<i>vs1</i> , <i>vsr</i>	Arrays: <i>vs1</i> (size at least $\max(1, \text{ldvs1}*n)$). If <i>jobvs1</i> = 'V', this array will contain the left Schur vectors. If <i>jobvs1</i> = 'N', <i>vs1</i> is not referenced. <i>vsr</i> (size at least $\max(1, \text{ldvsr}*n)$). If <i>jobvsr</i> = 'V', this array will contain the right Schur vectors. If <i>jobvsr</i> = 'N', <i>vsr</i> is not referenced.
<i>rconde</i> , <i>rcondv</i>	Arrays, size 2 each If <i>sense</i> = 'E' or 'B', <i>rconde</i>(1) and <i>rconde</i>(2) contain the reciprocal condition numbers for the average of the selected eigenvalues. Not referenced if <i>sense</i> = 'N' or 'V'.

If *sense* = 'V' or 'B', *rcondv*[0] and *rcondv*[1] contain the reciprocal condition numbers for the selected deflating subspaces.

Not referenced if *sense* = 'N' or 'E'.

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = *i*, and

i ≤ *n*:

the QZ iteration failed. (*A*, *B*) is not in Schur form, but *alphar*[*j*], *alphai*[*j*] (for real flavors), or *alpha*[*j*] (for complex flavors), and *beta*[*j*], *j* = *info*, ..., *n* - 1 should be correct.

i > *n*: errors that usually indicate LAPACK problems:

i = *n*+1: other than QZ iteration failed in [hgeqz](#);

i = *n*+2: after reordering, roundoff changed values of some complex eigenvalues so that leading eigenvalues in the generalized Schur form no longer satisfy *select* = 1. This could also be caused due to scaling;

i = *n*+3: reordering failed in [tgsen](#).

Application Notes

The quotients *alphar*[*j*]/*beta*[*j*] and *alphai*[*j*]/*beta*[*j*] may easily over- or underflow, and *beta*[*j*] may even be zero. Thus, you should avoid simply computing the ratio. However, *alphar* and *alphai* will be always less than and usually comparable with norm(*A*) in magnitude, and *beta* always less than and usually comparable with norm(*B*).

?ggev

Computes the generalized eigenvalues, and the left and/or right generalized eigenvectors for a pair of nonsymmetric matrices.

- `mk1.h`

Description

The `?ggeev` routine computes the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors for a pair of n -by- n real/complex nonsymmetric matrices (A,B) .

A generalized eigenvalue for a pair of matrices (A,B) is a scalar λ or a ratio $\alpha / \beta = \lambda$, such that $A - \lambda*B$ is singular. It is usually represented as the pair (α, β) , as there is a reasonable interpretation for $\beta = 0$ and even for both being zero.

The right generalized eigenvector $v(j)$ corresponding to the generalized eigenvalue $\lambda(j)$ of (A,B) satisfies $A*v(j) = \lambda(j)*B*v(j)$.

The left generalized eigenvector $u(j)$ corresponding to the generalized eigenvalue $\lambda(j)$ of (A,B) satisfies $u(j)^H*A = \lambda(j)*u(j)^H*B$

where $u(j)^H$ denotes the conjugate transpose of $u(j)$.

The `?ggeev` routine replaces the deprecated `?gegv` routine.

Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (<code>LAPACK_ROW_MAJOR</code>) or column major (<code>LAPACK_COL_MAJOR</code>).
<i>jobvl</i>	Must be 'N' or 'V'. If <i>jobvl</i> = 'N', the left generalized eigenvectors are not computed; If <i>jobvl</i> = 'V', the left generalized eigenvectors are computed.
<i>jobvr</i>	Must be 'N' or 'V'. If <i>jobvr</i> = 'N', the right generalized eigenvectors are not computed; If <i>jobvr</i> = 'V', the right generalized eigenvectors are computed.
<i>n</i>	The order of the matrices <i>A</i> , <i>B</i> , <i>vl</i> , and <i>vr</i> ($n \geq 0$).
<i>a</i> , <i>b</i>	Arrays: <i>a</i> (size at least $\max(1, lda*n)$) is an array containing the n -by- n matrix <i>A</i> (first of the pair of matrices). <i>b</i> (size at least $\max(1, ldb*n)$) is an array containing the n -by- n matrix <i>B</i> (second of the pair of matrices).
<i>lda</i>	The leading dimension of the array <i>a</i> . Must be at least $\max(1, n)$.
<i>ldb</i>	The leading dimension of the array <i>b</i> . Must be at least $\max(1, n)$.
<i>ldvl</i> , <i>ldvr</i>	The leading dimensions of the output matrices <i>vl</i> and <i>vr</i> , respectively. Constraints: <i>ldvl</i> ≥ 1 . If <i>jobvl</i> = 'V', <i>ldvl</i> $\geq \max(1, n)$. <i>ldvr</i> ≥ 1 . If <i>jobvr</i> = 'V', <i>ldvr</i> $\geq \max(1, n)$.

Output Parameters

<i>a, b</i>	On exit, these arrays have been overwritten.
<i>alphar, alphai</i>	Arrays, size at least $\max(1, n)$ each. Contain values that form generalized eigenvalues in real flavors. See <i>beta</i>.
<i>alpha</i>	Array, size at least $\max(1, n)$. Contain values that form generalized eigenvalues in complex flavors. See <i>beta</i>.
<i>beta</i>	Array, size at least $\max(1, n)$. <i>For real flavors:</i> On exit, $(\text{alphar}[j] + \text{alphai}[j]*i)/\text{beta}[j]$, $j=0, \dots, n-1$, are the generalized eigenvalues. If <i>alphai</i>[<i>j</i>] is zero, then the <i>j</i>-th eigenvalue is real; if positive, then the <i>j</i>-th and (<i>j</i>+1)-st eigenvalues are a complex conjugate pair, with <i>alphai</i>[<i>j</i>+1] negative. <i>For complex flavors:</i> On exit, $\text{alpha}[j]/\text{beta}[j]$, $j=0, \dots, n-1$, are the generalized eigenvalues. See also <i>Application Notes</i> below.
<i>vl, vr</i>	Arrays: <i>vl</i> (size at least $\max(1, \text{ldvl}*n)$). Contains the matrix of left generalized eigenvectors <i>VL</i>. If <i>jobvl</i> = 'V', the left generalized eigenvectors u_j are stored one after another in the columns of <i>VL</i>, in the same order as their eigenvalues. Each eigenvector is scaled so the largest component has $\text{abs}(\text{Re}) + \text{abs}(\text{Im}) = 1$. If <i>jobvl</i> = 'N', <i>vl</i> is not referenced. <i>For real flavors:</i> If the <i>j</i>-th eigenvalue is real, then the <i>k</i>-th component of the <i>j</i>-th left eigenvector u_j is stored in $\text{vl}[(k-1) + (j-1)*\text{ldvl}]$ for column major layout and in $\text{vl}[(k-1)*\text{ldvl} + (j-1)]$ for row major layout.. If the <i>j</i>-th and (<i>j</i>+1)-st eigenvalues form a complex conjugate pair, then for $i = \text{sqrt}(-1)$, the <i>k</i>-th components of the <i>j</i>-th left eigenvector u_j are $\text{vl}[(k-1) + (j-1)*\text{ldvl}] + i*\text{vl}[(k-1) + j*\text{ldvl}]$ for column major layout and $\text{vl}[(k-1)*\text{ldvl} + (j-1)] + i*\text{vl}[(k-1)*\text{ldvl} + j]$ for row major layout. Similarly, the <i>k</i>-th components of left eigenvector <i>j</i>+1 u_{j+1} are $\text{vl}[(k-1) + (j-1)*\text{ldvl}] - i*\text{vl}[(k-1) + j*\text{ldvl}]$ for column major layout and $\text{vl}[(k-1)*\text{ldvl} + (j-1)] - i*\text{vl}[(k-1)*\text{ldvl} + j]$ for row major layout.. <i>For complex flavors:</i> The <i>k</i>-th component of the <i>j</i>-th left eigenvector u_j is stored in $\text{vl}[(k-1) + (j-1)*\text{ldvl}]$ for column major layout and in $\text{vl}[(k-1)*\text{ldvl} + (j-1)]$ for row major layout. <i>vr</i> (size at least $\max(1, \text{ldvr}*n)$). Contains the matrix of right generalized eigenvectors <i>VR</i>.

If $jobv_r = 'V'$, the right generalized eigenvectors v_j are stored one after another in the columns of VR , in the same order as their eigenvalues. Each eigenvector is scaled so the largest component has $\text{abs}(\text{Re}) + \text{abs}(\text{Im}) = 1$.

If $jobv_r = 'N'$, vr is not referenced.

For real flavors:

If the j -th eigenvalue is real, then The k -th component of the j -th right eigenvector v_j is stored in $vr[(k - 1) + (j - 1)*ldvr]$ for column major layout and in $vr[(k - 1)*ldvr + (j - 1)]$ for row major layout..

If the j -th and $(j+1)$ -st eigenvalues form a complex conjugate pair, then the k -th components of the j -th right eigenvector v_j can be computed as $vr[(k - 1) + (j - 1)*ldvr] + i*vr[(k - 1) + j*ldvr]$ for column major layout and $vr[(k - 1)*ldvr + (j - 1)] + i*vr[(k - 1)*ldvr + j]$ for row major layout. Similarly, the k -th components of the right eigenvector $j+1$ v_{j+1} can be computed as $vr[(k - 1) + (j - 1)*ldvr] - i*vr[(k - 1) + j*ldvr]$ for column major layout and $vr[(k - 1)*ldvr + (j - 1)] - i*vr[(k - 1)*ldvr + j]$ for row major layout..

For complex flavors:

The k -th component of the j -th right eigenvector v_j is stored in $vr[(k - 1) + (j - 1)*ldvr]$ for column major layout and in $vr[(k - 1)*ldvr + (j - 1)]$ for row major layout.

Return Values

This function returns a value *info*.

If $info=0$, the execution is successful.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i$, and

$i \leq n$: the QZ iteration failed. No eigenvectors have been calculated, but *alphar*[j], *alphai*[j] (for real flavors), or *alpha*[j] (for complex flavors), and *beta*[j], $j=info, \dots, n - 1$ should be correct.

$i > n$: errors that usually indicate LAPACK problems:

$i = n+1$: other than QZ iteration failed in [hgeqz](#);

$i = n+2$: error return from [tgevc](#).

Application Notes

The quotients *alphar*[j]/*beta*[j] and *alphai*[j]/*beta*[j] may easily over- or underflow, and *beta*[j] may even be zero. Thus, you should avoid simply computing the ratio. However, *alphar* and *alphai* (for real flavors) or *alpha* (for complex flavors) will be always less than and usually comparable with $\text{norm}(A)$ in magnitude, and *beta* always less than and usually comparable with $\text{norm}(B)$.

?ggevx

Computes the generalized eigenvalues, and, optionally, the left and/or right generalized eigenvectors.

Description

The routine computes for a pair of n -by- n real/complex nonsymmetric matrices (A,B) , the generalized eigenvalues, and optionally, the left and/or right generalized eigenvectors.

Optionally also, it computes a balancing transformation to improve the conditioning of the eigenvalues and eigenvectors (ilo , ihi , $lscale$, $rscale$, $abnrm$, and $bbnrm$), reciprocal condition numbers for the eigenvalues ($rconde$), and reciprocal condition numbers for the right eigenvectors ($rcondv$).

A generalized eigenvalue for a pair of matrices (A,B) is a scalar λ or a ratio $alpha / beta = \lambda$, such that $A - \lambda*B$ is singular. It is usually represented as the pair $(alpha, beta)$, as there is a reasonable interpretation for $beta=0$ and even for both being zero. The right generalized eigenvector $v(j)$ corresponding to the generalized eigenvalue $\lambda(j)$ of (A,B) satisfies

$$A*v(j) = \lambda(j)*B*v(j).$$

The left generalized eigenvector $u(j)$ corresponding to the generalized eigenvalue $\lambda(j)$ of (A,B) satisfies

$$u(j)^H*A = \lambda(j)*u(j)^H*B$$

where $u(j)^H$ denotes the conjugate transpose of $u(j)$.

Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

<i>balanc</i>	Must be 'N', 'P', 'S', or 'B'. Specifies the balance option to be performed. If <i>balanc</i> = 'N', do not diagonally scale or permute; If <i>balanc</i> = 'P', permute only; If <i>balanc</i> = 'S', scale only; If <i>balanc</i> = 'B', both permute and scale. Computed reciprocal condition numbers will be for the matrices after balancing and/or permuting. Permuting does not change condition numbers (in exact arithmetic), but balancing does.
<i>jobvl</i>	Must be 'N' or 'V'. If <i>jobvl</i> = 'N', the left generalized eigenvectors are not computed; If <i>jobvl</i> = 'V', the left generalized eigenvectors are computed.
<i>jobvr</i>	Must be 'N' or 'V'. If <i>jobvr</i> = 'N', the right generalized eigenvectors are not computed; If <i>jobvr</i> = 'V', the right generalized eigenvectors are computed.
<i>sense</i>	Must be 'N', 'E', 'V', or 'B'. Determines which reciprocal condition number are computed. If <i>sense</i> = 'N', none are computed; If <i>sense</i> = 'E', computed for eigenvalues only; If <i>sense</i> = 'V', computed for eigenvectors only; If <i>sense</i> = 'B', computed for eigenvalues and eigenvectors.
<i>n</i>	The order of the matrices <i>A</i> , <i>B</i> , <i>vl</i> , and <i>vr</i> ($n \geq 0$).
<i>a, b</i>	Arrays: <i>a</i> (size at least $\max(1, lda*n)$) is an array containing the n-by-n matrix <i>A</i> (first of the pair of matrices). <i>b</i> (size at least $\max(1, ldb*n)$) is an array containing the n-by-n matrix <i>B</i> (second of the pair of matrices).
<i>lda</i>	The leading dimension of the array <i>a</i>. Must be at least $\max(1, n)$.
<i>ldb</i>	The leading dimension of the array <i>b</i>. Must be at least $\max(1, n)$.
<i>ldvl, ldvr</i>	The leading dimensions of the output matrices <i>vl</i> and <i>vr</i>, respectively. Constraints: $ldvl \geq 1$. If <i>jobvl</i> = 'V', $ldvl \geq \max(1, n)$. $ldvr \geq 1$. If <i>jobvr</i> = 'V', $ldvr \geq \max(1, n)$.

Output Parameters

<i>a, b</i>	On exit, these arrays have been overwritten. If <i>jobvl</i> = 'V' or <i>jobvr</i> = 'V' or both, then <i>a</i> contains the first part of the real Schur form of the "balanced" versions of the input <i>A</i> and <i>B</i>, and <i>b</i> contains its second part.
<i>alphar, alphai</i>	Arrays, size at least $\max(1, n)$ each. Contain values that form generalized eigenvalues in real flavors. See <i>beta</i>.
<i>alpha</i>	Array, size at least $\max(1, n)$. Contain values that form generalized eigenvalues in complex flavors. See <i>beta</i>.
<i>beta</i>	Array, size at least $\max(1, n)$. <i>For real flavors:</i> On exit, $(\text{alphar}[j] + \text{alphai}[j]*i)/\text{beta}[j]$, $j=0, \dots, n-1$, will be the generalized eigenvalues. If <i>alphai</i>[<i>j</i>] is zero, then the <i>j</i>-th eigenvalue is real; if positive, then the <i>j</i>-th and (<i>j</i>+1)-st eigenvalues are a complex conjugate pair, with <i>alphai</i>[<i>j</i>+1] negative. <i>For complex flavors:</i> On exit, $\text{alpha}[j]/\text{beta}[j]$, $j=0, \dots, n-1$, will be the generalized eigenvalues. See also <i>Application Notes</i> below.
<i>vl, vr</i>	Arrays: <i>vl</i> (size at least $\max(1, \text{ldvl}*n)$). If <i>jobvl</i> = 'V', the left generalized eigenvectors $u(j)$ are stored one after another in the columns of <i>vl</i>, in the same order as their eigenvalues. Each eigenvector will be scaled so the largest component have $\text{abs}(\text{Re}) + \text{abs}(\text{Im}) = 1$. If <i>jobvl</i> = 'N', <i>vl</i> is not referenced. <i>For real flavors:</i> If the <i>j</i>-th eigenvalue is real, then <i>k</i>-th component of <i>j</i>-th left eigenvector u_j is stored in $\text{vl}[(k-1) + (j-1)*\text{ldvl}]$ for column major layout and in $\text{vl}[(k-1)*\text{ldvl} + (j-1)]$ for row major layout.. If the <i>j</i>-th and (<i>j</i>+1)-st eigenvalues form a complex conjugate pair, then for $i = \text{sqrt}(-1)$, the <i>k</i>-th components of the <i>j</i>-th left eigenvector u_j can be computed as $\text{vl}[(k-1) + (j-1)*\text{ldvl}] + i*\text{vl}[(k-1) + j*\text{ldvl}]$ for column major layout and $\text{vl}[(k-1)*\text{ldvl} + (j-1)] + i*\text{vl}[(k-1)*\text{ldvl} + j]$ for row major layout. Similarly, the <i>k</i>-th components of the left eigenvector <i>j</i>+1 u_{j+1} can be computed as $\text{vl}[(k-1) + (j-1)*\text{ldvl}] - i*\text{vl}[(k-1) + j*\text{ldvl}]$ for column major layout and $\text{vl}[(k-1)*\text{ldvl} + (j-1)] - i*\text{vl}[(k-1)*\text{ldvl} + j]$ for row major layout.. <i>For complex flavors:</i>

The k -th component of the j -th left eigenvector u_j is stored in $vl[(k - 1) + (j - 1)*ldvl]$ for column major layout and in $vl[(k - 1)*ldvl + (j - 1)]$ for row major layout.

vr (size at least $\max(1, ldvr*n)$).

If $jobvr = 'V'$, the right generalized eigenvectors $v(j)$ are stored one after another in the columns of vr , in the same order as their eigenvalues. Each eigenvector will be scaled so the largest component have $\text{abs}(\text{Re}) + \text{abs}(\text{Im}) = 1$.

If $jobvr = 'N'$, vr is not referenced.

For real flavors:

If the j -th eigenvalue is real, then the k -th component of the j -th right eigenvector v_j is stored in $vr[(k - 1) + (j - 1)*ldvr]$ for column major layout and in $vr[(k - 1)*ldvr + (j - 1)]$ for row major layout..

If the j -th and $(j+1)$ -st eigenvalues form a complex conjugate pair, then The k -th components of the j -th right eigenvector v_j can be computed as $vr[(k - 1) + (j - 1)*ldvr] + i*vr[(k - 1) + j*ldvr]$ for column major layout and $vr[(k - 1)*ldvr + (j - 1)] + i*vr[(k - 1)*ldvr + j]$ for row major layout. Respectively, the k -th components of right eigenvector $j+1$ v_{j+1} can be computed as $vr[(k - 1) + (j - 1)*ldvr] - i*vr[(k - 1) + j*ldvr]$ for column major layout and $vr[(k - 1)*ldvr + (j - 1)] - i*vr[(k - 1)*ldvr + j]$ for row major layout..

For complex flavors:

The k -th component of the j -th right eigenvector v_j is stored in $vr[(k - 1) + (j - 1)*ldvr]$ for column major layout and in $vr[(k - 1)*ldvr + (j - 1)]$ for row major layout.

ilo, ihi

ilo and ihi are integer values such that on exit $A_{i,j} = 0$ and $B_{i,j} = 0$ if $i > j$ and $j = 1, \dots, ilo-1$ or $i = ihi+1, \dots, n$.

If $balanc = 'N'$ or $'S'$, $ilo = 1$ and $ihi = n$.

$lscale, rscale$

Arrays, size at least $\max(1, n)$ each.

$lscale$ contains details of the permutations and scaling factors applied to the left side of A and B .

If $PL(j)$ is the index of the row interchanged with row j , and $DL(j)$ is the scaling factor applied to row j , then

$lscale[j - 1] = PL(j)$, for $j = 1, \dots, ilo-1$

$= DL(j)$, for $j = ilo, \dots, ihi$

$= PL(j)$ for $j = ihi+1, \dots, n$.

The order in which the interchanges are made is n to $ihi+1$, then 1 to $ilo-1$.

$rscale$ contains details of the permutations and scaling factors applied to the right side of A and B .

If $PR(j)$ is the index of the column interchanged with column j , and $DR(j)$ is the scaling factor applied to column j , then

$rscale[j - 1] = PR(j)$, for $j = 1, \dots, ilo-1$

$= DR(j)$, for $j = ilo, \dots, ihi$

$= PR(j)$ for $j = ihi+1, \dots, n$.

The order in which the interchanges are made is n to $ihi+1$, then 1 to $ilo-1$.

abnrm, bbnrm

The one-norms of the balanced matrices A and B , respectively.

rconde, rcondv

Arrays, size at least $\max(1, n)$ each.

If *sense* = 'E', or 'B', *rconde* contains the reciprocal condition numbers of the eigenvalues, stored in consecutive elements of the array. For a complex conjugate pair of eigenvalues two consecutive elements of *rconde* are set to the same value. Thus *rconde*[*j*], *rcondv*[*j*], and the *j*-th columns of *vl* and *vr* all correspond to the same eigenpair (but not in general the *j*-th eigenpair, unless all eigenpairs are selected).

If *sense* = 'N', or 'V', *rconde* is not referenced.

If *sense* = 'V', or 'B', *rcondv* contains the estimated reciprocal condition numbers of the eigenvectors, stored in consecutive elements of the array. For a complex eigenvector two consecutive elements of *rcondv* are set to the same value.

If the eigenvalues cannot be reordered to compute *rcondv*[*j*] is set to 0; this can only occur when the true value would be very small anyway.

If *sense* = 'N', or 'E', *rcondv* is not referenced.

Return Values

This function returns a value *info*.

If *info*=0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = *i*, and

$i \leq n$: the QZ iteration failed. No eigenvectors have been calculated, but *alphas*[*j*], *alphai*[*j*] (for real flavors), or *alpha*[*j*] (for complex flavors), and *beta*[*j*], $j=info, \dots, n-1$ should be correct.

$i > n$: errors that usually indicate LAPACK problems:

$i = n+1$: other than QZ iteration failed in [hgeqz](#);

$i = n+2$: error return from [tgevc](#).

Application Notes

The quotients *alphas*[*j*]/*beta*[*j*] and *alphai*[*j*]/*beta*[*j*] may easily over- or underflow, and *beta*[*j*] may even be zero. Thus, you should avoid simply computing the ratio. However, *alphas* and *alphai* (for real flavors) or *alpha* (for complex flavors) will be always less than and usually comparable with $\text{norm}(A)$ in magnitude, and *beta* always less than and usually comparable with $\text{norm}(B)$.

Auxiliary Routines

Routine naming conventions, mathematical notation, and matrix storage schemes used for LAPACK auxiliary routines are the same as for the driver and computational routines described in previous chapters.

?lacgv

Conjugates a complex vector.

Syntax

```
lapack_int LAPACKE_clacgv (lapack_int n, lapack_complex_float* x, lapack_int incx);
lapack_int LAPACKE_zlacgv (lapack_int n, lapack_complex_double* x, lapack_int incx);
```

Include Files

- mkl.h

Description

The routine conjugates a complex vector x of length n and increment $incx$ (see "[Vector Arguments in BLAS](#)" in Appendix B).

Input Parameters

n	The length of the vector x ($n \geq 0$).
x	Array, dimension $(1+(n-1) * incx)$. Contains the vector of length n to be conjugated.
$incx$	The spacing between successive elements of x .

Output Parameters

x	On exit, overwritten with $\text{conjg}(x)$.

?ssyconv

Converts a symmetric matrix given by a triangular matrix factorization into two matrices and vice versa.

Syntax

```
lapack_int LAPACKE_ssyconv (int matrix_layout, char uplo, char way, lapack_int n, float
* a, lapack_int lda, const lapack_int * ipiv);

lapack_int LAPACKE_dsyconv (int matrix_layout, char uplo, char way, lapack_int n,
double* a, lapack_int lda, const lapack_int * ipiv);

lapack_int LAPACKE_csyconv (int matrix_layout, char uplo, char way, lapack_int n,
lapack_complex_float * a, lapack_int lda, const lapack_int * ipiv);

lapack_int LAPACKE_zsyconv (int matrix_layout, char uplo, char way, lapack_int n,
lapack_complex_double* a, lapack_int lda, const lapack_int * ipiv);
```

Include Files

- mkl.h

Description

The routine converts matrix A , which results from a triangular matrix factorization, into matrices L and D and vice versa. The routine gets non-diagonalized elements of D returned in the workspace and applies or reverses permutation done with the triangular matrix factorization.

Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>uplo</i>	Must be 'U' or 'L'. Indicates whether the details of the factorization are stored as an upper or lower triangular matrix: If <i>uplo</i> = 'U': the upper triangular, $A = U * D * U^T$. If <i>uplo</i> = 'L': the lower triangular, $A = L * D * L^T$.
<i>way</i>	Must be 'C' or 'R'.
<i>n</i>	The order of matrix <i>A</i> ; $n \geq 0$.
<i>a</i>	Array of size $\max(1, lda * n)$. The block diagonal matrix <i>D</i> and the multipliers used to obtain the factor <i>U</i> or <i>L</i> as computed by ?sytrf.
<i>lda</i>	The leading dimension of <i>a</i> ; $lda \geq \max(1, n)$.
<i>ipiv</i>	Array, size at least $\max(1, n)$. Details of the interchanges and the block structure of <i>D</i> , as returned by ?sytrf.

Return Values

<i>info</i>	If <i>info</i> = 0, the execution is successful. If <i>info</i> < 0, the <i>i</i> -th parameter had an illegal value. If <i>info</i> = -1011, memory allocation error occurred.

See Also

[?sytrf](#)

?syr

Performs the symmetric rank-1 update of a complex symmetric matrix.

Syntax

```
lapack_int LAPACKE_csyr (int matrix_layout, char uplo, lapack_int n,
lapack_complex_float alpha, const lapack_complex_float * x, lapack_int incx,
lapack_complex_float * a, lapack_int lda);

lapack_int LAPACKE_zsyr (int matrix_layout, char uplo, lapack_int n,
lapack_complex_double alpha, const lapack_complex_double * x, lapack_int incx,
lapack_complex_double * a, lapack_int lda);
```

Include Files

- mkl.h

Description

The routine performs the symmetric rank 1 operation defined as

$$a := \alpha * x * x^H + a,$$

where:

- α is a complex scalar.
- x is an n -element complex vector.
- a is an n -by- n complex symmetric matrix.

These routines have their real equivalents in BLAS (see [?syr](#) in Chapter 2).

Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>uplo</i>	Specifies whether the upper or lower triangular part of the array a is used: If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the array a is used. If <i>uplo</i> = 'L' or 'l', then the lower triangular part of the array a is used.
<i>n</i>	Specifies the order of the matrix a . The value of n must be at least zero.
<i>alpha</i>	Specifies the scalar α .
<i>x</i>	Array, size at least $(1 + (n - 1) * \text{abs}(incx))$. Before entry, the incremented array x must contain the n -element vector x .
<i>incx</i>	Specifies the increment for the elements of x . The value of <i>incx</i> must not be zero.
<i>a</i>	Array, size $\max(1, lda * n)$. Before entry with <i>uplo</i> = 'U' or 'u', the leading n -by- n upper triangular part of the array a must contain the upper triangular part of the symmetric matrix and the strictly lower triangular part of a is not referenced. Before entry with <i>uplo</i> = 'L' or 'l', the leading n -by- n lower triangular part of the array a must contain the lower triangular part of the symmetric matrix and the strictly upper triangular part of a is not referenced.
<i>lda</i>	Specifies the leading dimension of a as declared in the calling (sub)program. The value of <i>lda</i> must be at least $\max(1, n)$.

Output Parameters

<i>a</i>	With <i>uplo</i> = 'U' or 'u', the upper triangular part of the array a is overwritten by the upper triangular part of the updated matrix. With <i>uplo</i> = 'L' or 'l', the lower triangular part of the array a is overwritten by the lower triangular part of the updated matrix.

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* < 0, the i -th parameter had an illegal value.

If `info = -1011`, memory allocation error occurred.

i?max1

Finds the index of the vector element whose real part has maximum absolute value.

Syntax

```
MKL_INT icmax1(const MKL_INT*n, const MKL_Complex8*cx, const MKL_INT*incx)
MKL_INT izmax1(const MKL_INT*n, const MKL_Complex16*cx, const MKL_INT*incx)
```

Include Files

- `mk1.h`

Description

Given a complex vector `cx`, the `i?max1` functions return the index of the first vector element of maximum absolute value. These functions are based on the BLAS functions `icamax/izamax`, but using the absolute value of components. They are designed for use with `clacon/zlacon`.

Input Parameters

<code>n</code>	Specifies the number of elements in the vector <code>cx</code> .
<code>cx</code>	Array, size at least $(1 + (n-1) * \text{abs}(incx))$. Contains the input vector.
<code>incx</code>	Specifies the spacing between successive elements of <code>cx</code> .

Return Values

Index of the vector element of maximum absolute value.

?sum1

Forms the 1-norm of the complex vector using the true absolute value.

Syntax

```
float ssum1(const MKL_INT*n, const MKL_Complex8*cx, const MKL_INT*incx)
double dsum1(const MKL_INT*n, const MKL_Complex16*cx, const MKL_INT*incx)
```

Include Files

- `mk1.h`

Description

Given a complex vector `cx`, `ssum1/dsum1` functions take the sum of the absolute values of vector elements and return a single/double precision result, respectively. These functions are based on `scasum/dzasum` from Level 1 BLAS, but use the true absolute value and were designed for use with `clacon/zlacon`.

Input Parameters

n	Specifies the number of elements in the vector cx .
cx	Array, size at least $(1+(n-1)*abs(incx))$. Contains the input vector whose elements will be summed.
$incx$	Specifies the spacing between successive elements of cx ($incx > 0$).

Return Values

Sum of absolute values.

?gelq2

Computes the LQ factorization of a general rectangular matrix using an unblocked algorithm.

Syntax

```
lapack_int LAPACKE_sgelq2 (int matrix_layout, lapack_int m, lapack_int n, float* a,
lapack_int lda, float* tau);

lapack_int LAPACKE_dgelq2 (int matrix_layout, lapack_int m, lapack_int n, double* a,
lapack_int lda, double * tau);

lapack_int LAPACKE_cgelq2 (int matrix_layout, lapack_int m, lapack_int n,
lapack_complex_float* a, lapack_int lda, lapack_complex_float* tau);

lapack_int LAPACKE_zgelq2 (int matrix_layout, lapack_int m, lapack_int n,
lapack_complex_double* a, lapack_int lda, lapack_complex_double* tau);
```

Include Files

- mkl.h

Description

The routine computes an LQ factorization of a real/complex m -by- n matrix A as $A = L*Q$.

The routine does not form the matrix Q explicitly. Instead, Q is represented as a product of $\min(m, n)$ elementary reflectors :

$Q = H(k) \dots H(2) H(1)$ (or $Q = H(k)^H \dots H(2)^H H(1)^H$ for complex flavors), where $k = \min(m, n)$

Each $H(i)$ has the form

$H(i) = I - \tau v v^T$ for real flavors, or

$H(i) = I - \tau v v^H$ for complex flavors,

where τ is a real/complex scalar stored in $\tau(i)$, and v is a real/complex vector with $v_{1:i-1} = 0$ and $v_i = 1$.

On exit, the j -th ($i+1 \leq j \leq n$) component of vector v (for real functions) or its conjugate (for complex functions) is stored in $a[i-1+lda*(j-1)]$ for column major layout or in $a[j-1+lda*(i-1)]$ for row major layout.

Input Parameters

<i>m</i>	The number of rows in the matrix <i>A</i> ($m \geq 0$).
<i>n</i>	The number of columns in <i>A</i> ($n \geq 0$).
<i>a</i>	Array, size at least $\max(1, lda \cdot n)$ for column major and $\max(1, lda \cdot m)$ for row major layout. Array <i>a</i> contains the <i>m</i> -by- <i>n</i> matrix <i>A</i> .
<i>lda</i>	The leading dimension of <i>a</i> ; at least $\max(1, m)$ for column major layout and $\max(1, n)$ for row major layout.

Output Parameters

<i>a</i>	Overwritten by the factorization data as follows: on exit, the elements on and below the diagonal of the array <i>a</i> contain the <i>m</i> -by- $\min(n, m)$ lower trapezoidal matrix <i>L</i> (<i>L</i> is lower triangular if $n \geq m$); the elements above the diagonal, with the array <i>tau</i> , represent the orthogonal/unitary matrix <i>Q</i> as a product of $\min(n, m)$ elementary reflectors.
<i>tau</i>	Array, size at least $\max(1, \min(m, n))$. Contains scalar factors of the elementary reflectors.

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = -1011, memory allocation error occurred.

?sgeqr2

Computes the QR factorization of a general rectangular matrix using an unblocked algorithm.

Syntax

```
lapack_int LAPACKE_sgeqr2 (int matrix_layout, lapack_int m, lapack_int n, float* a,
lapack_int lda, float* tau);

lapack_int LAPACKE_dgeqr2 (int matrix_layout, lapack_int m, lapack_int n, double* a,
lapack_int lda, double* tau);

lapack_int LAPACKE_cgeqr2 (int matrix_layout, lapack_int m, lapack_int n,
lapack_complex_float* a, lapack_int lda, lapack_complex_float* tau);

lapack_int LAPACKE_zgeqr2 (int matrix_layout, lapack_int m, lapack_int n,
lapack_complex_double* a, lapack_int lda, lapack_complex_double* tau);
```

Include Files

- mkl.h

Description

The routine computes a QR factorization of a real/complex *m*-by-*n* matrix *A* as $A = Q \cdot R$.

The routine does not form the matrix Q explicitly. Instead, Q is represented as a product of $\min(m, n)$ *elementary reflectors* :

$Q = H(1) * H(2) * \dots * H(k)$, where $k = \min(m, n)$

Each $H(i)$ has the form

$H(i) = I - \tau v v^T$ for real flavors, or

$H(i) = I - \tau v v^H$ for complex flavors

where τ is a real/complex scalar stored in $\tau[i]$, and v is a real/complex vector with $v_{1:i-1} = 0$ and $v_i = 1$.

On exit, $v_{i+1:m}$ is stored in $a(i+1:m, i)$.

Input Parameters

m	The number of rows in the matrix A ($m \geq 0$).
n	The number of columns in A ($n \geq 0$).
a	Array, size at least $\max(1, lda * n)$ for column major and $\max(1, lda * m)$ for row major layout. Array a contains the m -by- n matrix A .
lda	The leading dimension of a ; at least $\max(1, m)$ for column major layout and $\max(1, n)$ for row major layout.

Output Parameters

a	Overwritten by the factorization data as follows: on exit, the elements on and above the diagonal of the array a contain the $\min(n, m)$ -by- n upper trapezoidal matrix R (R is upper triangular if $m \geq n$); the elements below the diagonal, with the array τ , represent the orthogonal/unitary matrix Q as a product of elementary reflectors.
τ	Array, size at least $\max(1, \min(m, n))$. Contains scalar factors of the elementary reflectors.

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = -1011, memory allocation error occurred.

?sgeqrt2

Computes a QR factorization of a general real or complex matrix using the compact WY representation of Q .

Syntax

```
lapack_int LAPACKE_sgeqrt2 (int matrix_layout, lapack_int m, lapack_int n, float * a,
lapack_int lda, float * t, lapack_int ldt );
```

```
lapack_int LAPACKE_dgeqrt2 (int matrix_layout, lapack_int m, lapack_int n, double * a,
lapack_int lda, double * t, lapack_int ldt );

lapack_int LAPACKE_cgeqrt2 (int matrix_layout, lapack_int m, lapack_int n,
lapack_complex_float * a, lapack_int lda, lapack_complex_float * t, lapack_int ldt );

lapack_int LAPACKE_zgeqrt2 (int matrix_layout, lapack_int m, lapack_int n,
lapack_complex_double * a, lapack_int lda, lapack_complex_double * t, lapack_int ldt );
```

Include Files

- mkl.h

Description

The strictly lower triangular matrix V contains the elementary reflectors $H(i)$ in the i th column below the diagonal. For example, if $m=5$ and $n=3$, the matrix V is

$$V = \begin{bmatrix} 1 & & & & \\ v_1 & 1 & & & \\ v_1 & v_2 & 1 & & \\ v_1 & v_2 & v_3 & & \\ v_1 & v_2 & v_3 & & \end{bmatrix}$$

where v_i represents the vector that defines $H(i)$. The vectors are returned in the lower triangular part of array a .

NOTE

The 1s along the diagonal of V are not stored in a .

The block reflector H is then given by

$H = I - V^* T^* V^T$ for real flavors, and

$H = I - V^* T^* V^H$ for complex flavors,

where V^T is the transpose and V^H is the conjugate transpose of V .

Input Parameters

m	The number of rows in the matrix A ($m \geq n$).
n	The number of columns in A ($n \geq 0$).
a	Array, size at least $\max(1, lda * n)$ for column major and $\max(1, lda * m)$ for row major layout. Array a contains the m -by- n matrix A .
lda	The leading dimension of a ; at least $\max(1, m)$ for column major layout and $\max(1, n)$ for row major layout.
ldt	The leading dimension of t ; at least $\max(1, n)$.

Output Parameters

<i>a</i>	Overwritten by the factorization data as follows: The elements on and above the diagonal of the array contain the n -by- n upper triangular matrix R . The elements below the diagonal are the columns of V .
<i>t</i>	Array, size at least $\max(1, \text{ldt} * n)$. The n -by- n upper triangular factor of the block reflector. The elements on and above the diagonal contain the block reflector T . The elements below the diagonal are not used.

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* < 0 and *info* = -*i*, the *i*th argument had an illegal value.

If *info* = -1011, memory allocation error occurred.

?geqrt3

Recursively computes a QR factorization of a general real or complex matrix using the compact WY representation of Q.

Syntax

```
lapack_int LAPACKGE_sgeqrt3 (int matrix_layout , lapack_int m , lapack_int n , float *
a , lapack_int lda , float * t , lapack_int ldt );

lapack_int LAPACKGE_dgeqrt3 (int matrix_layout , lapack_int m , lapack_int n , double *
a , lapack_int lda , double * t , lapack_int ldt );

lapack_int LAPACKGE_cgeqrt3 (int matrix_layout , lapack_int m , lapack_int n ,
lapack_complex_float * a , lapack_int lda , lapack_complex_float * t , lapack_int
ldt );

lapack_int LAPACKGE_zgeqrt3 (int matrix_layout , lapack_int m , lapack_int n ,
lapack_complex_double * a , lapack_int lda , lapack_complex_double * t , lapack_int
ldt );
```

Include Files

- mkl.h

Description

The strictly lower triangular matrix V contains the elementary reflectors $H(i)$ in the i th column below the diagonal. For example, if $m=5$ and $n=3$, the matrix V is

$$V = \begin{bmatrix} 1 & & & \\ v_1 & 1 & & \\ v_1 & v_2 & 1 & \\ v_1 & v_2 & v_3 & \\ v_1 & v_2 & v_3 & \end{bmatrix}$$

where v_i represents one of the vectors that define $H(i)$. The vectors are returned in the lower part of triangular array a .

NOTE

The 1s along the diagonal of V are not stored in a .

The block reflector H is then given by

$H = I - V^* T^* V^T$ for real flavors, and

$H = I - V^* T^* V^H$ for complex flavors,

where V^T is the transpose and V^H is the conjugate transpose of V .

Input Parameters

m	The number of rows in the matrix A ($m \geq n$).
n	The number of columns in A ($n \geq 0$).
a	Array, size at least $\max(1, lda * n)$ for column major and $\max(1, lda * m)$ for row major layout. Array a contains the m -by- n matrix A .
lda	The leading dimension of a ; at least $\max(1, m)$ for column major layout and $\max(1, n)$ for row major layout.
ldt	The leading dimension of t ; at least $\max(1, n)$.

Output Parameters

a	The elements on and above the diagonal of the array contain the n -by- n upper triangular matrix R . The elements below the diagonal are the columns of V .
t	Array, size ldt by n . The n -by- n upper triangular factor of the block reflector. The elements on and above the diagonal contain the block reflector T . The elements below the diagonal are not used.

Return Values

This function returns a value *info*.

If $info = 0$, the execution is successful.

If $info < 0$ and $info = -i$, the i th argument had an illegal value.

If `info = -1011`, memory allocation error occurred.

?getf2

Computes the LU factorization of a general m -by- n matrix using partial pivoting with row interchanges (unblocked algorithm).

Syntax

```
lapack_int LAPACK_sgetf2 (int matrix_layout, lapack_int m, lapack_int n, float* a,
lapack_int lda, lapack_int * ipiv);

lapack_int LAPACK_dgetf2 (int matrix_layout, lapack_int m, lapack_int n, double* a,
lapack_int lda, lapack_int * ipiv);

lapack_int LAPACK_cgetf2 (int matrix_layout, lapack_int m, lapack_int n,
lapack_complex_float* a, lapack_int lda, lapack_int * ipiv);

lapack_int LAPACK_zgetf2 (int matrix_layout, lapack_int m, lapack_int n,
lapack_complex_double* a, lapack_int lda, lapack_int * ipiv);
```

Include Files

- `mk1.h`

Description

The routine computes the LU factorization of a general m -by- n matrix A using partial pivoting with row interchanges. The factorization has the form

$$A = P * L * U$$

where p is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if $m > n$) and U is upper triangular (upper trapezoidal if $m < n$).

Input Parameters

m	The number of rows in the matrix A ($m \geq 0$).
n	The number of columns in A ($n \geq 0$).
a	Array, size at least $\max(1, lda * n)$ for column major and $\max(1, lda * m)$ for row major layout. Array a contains the m -by- n matrix A .
lda	The leading dimension of a ; at least $\max(1, m)$ for column major layout and $\max(1, n)$ for row major layout.

Output Parameters

a	Overwritten by L and U . The unit diagonal elements of L are not stored.
$ipiv$	Array, size at least $\max(1, \min(m, n))$. The pivot indices: for $1 \leq i \leq n$, row i was interchanged with row $ipiv(i)$.

Return Values

This function returns a value `info`.

If $info = -i$, the i -th parameter had an illegal value.

If $info = i > 0$, U_{ii} is 0. The factorization has been completed, but U is exactly singular. Division by 0 will occur if you use the factor U for solving a system of linear equations.

If $info = -1011$, memory allocation error occurred.

?lacn2

Estimates the 1-norm of a square matrix, using reverse communication for evaluating matrix-vector products.

Syntax

C:

```
lapack_int LAPACKE_slacn2 (lapack_int n, float * v, float * x, lapack_int * isgn, float
* est, lapack_int * kase, lapack_int * isave);

lapack_int LAPACKE_clacn2 (lapack_int n, lapack_complex_float * v, lapack_complex_float
* x, float * est, lapack_int * kase, lapack_int * isave);

lapack_int LAPACKE_dlacn2 (lapack_int n, double * v, double * x, lapack_int * isgn,
double * est, lapack_int * kase, lapack_int * isave);

lapack_int LAPACKE_zlacn2 (lapack_int n, lapack_complex_double * v,
lapack_complex_double * x, double * est, lapack_int * kase, lapack_int * isave);
```

Include Files

- mkl.h

Description

The routine estimates the 1-norm of a square, real or complex matrix A . Reverse communication is used for evaluating matrix-vector products.

Input Parameters

n	The order of the matrix A ($n \geq 1$).
v, x	Arrays, size (n) each. v is a workspace array. x is used as input after an intermediate return.
$isgn$	Workspace array, size (n), used with real flavors only.
est	On entry with $kase$ set to 1 or 2, and $isave(1) = 1$, est must be unchanged from the previous call to the routine.
$kase$	On the initial call to the routine, $kase$ must be set to 0.
$isave$	Array, size (3). Contains variables from the previous call to the routine.

Output Parameters

<i>est</i>	An estimate (a lower bound) for $\text{norm}(A)$.
<i>kase</i>	On an intermediate return, <i>kase</i> is set to 1 or 2, indicating whether <i>x</i> is overwritten by $A*x$ or A^T*x for real flavors and $A*x$ or A^H*x for complex flavors. On the final return, <i>kase</i> is set to 0.
<i>v</i>	On the final return, $v = A*w$, where $est = \text{norm}(v)/\text{norm}(w)$ (<i>w</i> is not returned).
<i>x</i>	On an intermediate return, <i>x</i> is overwritten by $A*x$, if <i>kase</i> = 1, A^T*x , if <i>kase</i> = 2 (for real flavors), A^H*x , if <i>kase</i> = 2 (for complex flavors), and the routine must be re-called with all the other parameters unchanged.
<i>isave</i>	This parameter is used to save variables between calls to the routine.

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

?lacpy

Copies all or part of one two-dimensional array to another.

Syntax

```
lapack_int LAPACKE_slacpy (int matrix_layout, char uplo, lapack_int m, lapack_int n,
const float* a, lapack_int lda, float* b, lapack_int ldb);
```

```
lapack_int LAPACKE_dlacpy (int matrix_layout, char uplo, lapack_int m, lapack_int n,
const double* a, lapack_int lda, double* b, lapack_int ldb);
```

```
lapack_int LAPACKE_clacpy (int matrix_layout, char uplo, lapack_int m, lapack_int n,
const lapack_complex_float* a, lapack_int lda, lapack_complex_float* b, lapack_int
ldb);
```

```
lapack_int LAPACKE_zlacpy (int matrix_layout, char uplo, lapack_int m, lapack_int n,
const lapack_complex_double* a, lapack_int lda, lapack_complex_double* b, lapack_int
ldb);
```

Include Files

- mkl.h

Description

The routine copies all or part of a two-dimensional matrix *A* to another matrix *B*.

Input Parameters

<i>uplo</i>	Specifies the part of the matrix <i>A</i> to be copied to <i>B</i> . If <i>uplo</i> = 'U', the upper triangular part of <i>A</i> ; if <i>uplo</i> = 'L', the lower triangular part of <i>A</i> . Otherwise, all of the matrix <i>A</i> is copied.
<i>m</i>	The number of rows in the matrix <i>A</i> ($m \geq 0$).
<i>n</i>	The number of columns in <i>A</i> ($n \geq 0$).
<i>a</i>	Array, size at least $\max(1, lda*n)$ for column major and $\max(1, lda*m)$ for row major layout. <i>A</i> contains the <i>m</i> -by- <i>n</i> matrix <i>A</i> . If <i>uplo</i> = 'U', only the upper triangle or trapezoid is accessed; if <i>uplo</i> = 'L', only the lower triangle or trapezoid is accessed.
<i>lda</i>	The leading dimension of <i>a</i> ; $lda \geq \max(1, m)$ for column major layout and $\max(1, n)$ for row major layout.
<i>ldb</i>	The leading dimension of the output array <i>b</i> ; $ldb \geq \max(1, m)$ for column major layout and $\max(1, n)$ for row major layout.

Output Parameters

<i>b</i>	Array, size at least $\max(1, ldb*n)$ for column major and $\max(1, ldb*m)$ for row major layout. Array <i>a</i> contains the <i>m</i> -by- <i>n</i> matrix <i>B</i> . On exit, $B = A$ in the locations specified by <i>uplo</i> .

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

?lakf2

Forms a matrix containing Kronecker products between the given matrices.

Syntax

```
void slakf2 (lapack_int *m, lapack_int *n, float *a, lapack_int *lda, float *b, float
*d, float *e, float *z, lapack_int *ldz);

void dlakf2 (lapack_int *m, lapack_int *n, double *a, lapack_int *lda, double *b,
double *d, double *e, double *z, lapack_int *ldz);

void clakf2 (lapack_int *m, lapack_int *n, lapack_complex *a, lapack_int *lda,
lapack_complex *b, lapack_complex *d, lapack_complex *e, lapack_complex *z, lapack_int
*ldz);

void zlakf2 (lapack_int *m, lapack_int *n, lapack_complex_double *a, lapack_int *lda,
lapack_complex_double *b, lapack_complex_double *d, lapack_complex_double *e,
lapack_complex_double *z, lapack_int *ldz);
```

Include Files

- `mk1.h`

Description

The routine `?lakf2` forms the $2*m*n$ by $2*m*n$ matrix Z .

$$Z = \begin{bmatrix} \text{kron}(In, A) & -\text{kron}(B^T, Im) \\ \text{kron}(In, D) & -\text{kron}(E^T, Im) \end{bmatrix},$$

where In is the identity matrix of size n and X^T is the transpose of X . $\text{kron}(X, Y)$ is the Kronecker product between the matrices X and Y .

Input Parameters

m	Size of matrix, $m \geq 1$
n	Size of matrix, $n \geq 1$
a	Array, size lda -by- n . The matrix A in the output matrix Z .
lda	The leading dimension of a , b , d , and e . $lda \geq m+n$.
b	Array, size lda by n . Matrix used in forming the output matrix Z .
d	Array, size lda by m . Matrix used in forming the output matrix Z .
e	Array, size lda by n . Matrix used in forming the output matrix Z .
ldz	The leading dimension of Z . $ldz \geq 2 * m * n$.

Output Parameters

z	Array, size ldz -by- $2*m*n$. The resultant Kronecker $m*n*2$ -by- $m*n*2$ matrix.

?lange

Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element of a general rectangular matrix.

Syntax

```
float LAPACKE_slange (int matrix_layout, char norm, lapack_int m, lapack_int n, const float * a, lapack_int lda);
```

```
double LAPACKE_dlange (int matrix_layout, char norm, lapack_int m, lapack_int n, const double * a, lapack_int lda);
```

```
float LAPACKE_clange (int matrix_layout, char norm, lapack_int m, lapack_int n, const lapack_complex_float * a, lapack_int lda);
```

```
double LAPACKE_zlange (int matrix_layout, char norm, lapack_int m, lapack_int n, const lapack_complex_double * a, lapack_int lda);
```

Include Files

- mkl.h

Description

The function `?lange` returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a real/complex matrix A .

Input Parameters

<i>norm</i>	Specifies the value to be returned by the routine: = 'M' or 'm': $val = \max(\text{abs}(A_{ij})),$ largest absolute value of the matrix A . = '1' or 'O' or 'o': $val = \text{norm1}(A),$ 1-norm of the matrix A (maximum column sum), = 'I' or 'i': $val = \text{normI}(A),$ infinity norm of the matrix A (maximum row sum), = 'F', 'f', 'E' or 'e': $val = \text{normF}(A),$ Frobenius norm of the matrix A (square root of sum of squares).
<i>m</i>	The number of rows of the matrix A . $m \geq 0$. When $m = 0$, <code>?lange</code> is set to zero.
<i>n</i>	The number of columns of the matrix A . $n \geq 0$. When $n = 0$, <code>?lange</code> is set to zero.
<i>a</i>	Array, size at least $\max(1, lda*n)$ for column major and $\max(1, lda*m)$ for row major layout. Array a contains the m -by- n matrix A .
<i>lda</i>	The leading dimension of the array a . $lda \geq \max(n, 1)$ for column major layout and $\max(1, n)$ for row major layout.

?lansy

Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a real/complex symmetric matrix.

Syntax

```
float LAPACKE_slansy (int matrix_layout, char norm, char uplo, lapack_int n, const
float * a, lapack_int lda);

double LAPACKE_dlansy (int matrix_layout, char norm, char uplo, lapack_int n, const
double * a, lapack_int lda);

float LAPACKE_clansy (int matrix_layout, char norm, char uplo, lapack_int n, const
lapack_complex_float * a, lapack_int lda);

double LAPACKE_zlansy (int matrix_layout, char norm, char uplo, lapack_int n, const
lapack_complex_double * a, lapack_int lda);
```

Include Files

- `mk1.h`

Description

The function `?lansy` returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a real/complex symmetric matrix A .

Input Parameters

<i>norm</i>	Specifies the value to be returned by the routine: = 'M' or 'm': $val = \max(\text{abs}(A_{ij}))$, largest absolute value of the matrix A. = '1' or 'O' or 'o': $val = \text{norm1}(A)$, 1-norm of the matrix A (maximum column sum), = 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix A (maximum row sum), = 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix A (square root of sum of squares).
<i>uplo</i>	Specifies whether the upper or lower triangular part of the symmetric matrix A is to be referenced. = 'U': Upper triangular part of A is referenced. = 'L': Lower triangular part of A is referenced
<i>n</i>	The order of the matrix A . $n \geq 0$. When $n = 0$, <code>?lan_{sy}</code> is set to zero.
<i>a</i>	Array, size at least $\max(1, lda*n)$. The symmetric matrix A. If <i>uplo</i> = 'U', the leading n-by-n upper triangular part of <i>a</i> contains the upper triangular part of the matrix A, and the strictly lower triangular part of <i>a</i> is not referenced. If <i>uplo</i> = 'L', the leading n-by-n lower triangular part of <i>a</i> contains the lower triangular part of the matrix A, and the strictly upper triangular part of <i>a</i> is not referenced.
<i>lda</i>	The leading dimension of the array <i>a</i>. $lda \geq \max(n, 1)$.

?lanhe

Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a complex Hermitian matrix.

Syntax

```
float LAPACKE_clanhe (int matrix_layout, char norm, char uplo, lapack_int n, const
lapack_complex_float * a, lapack_int lda);

double LAPACKE_zlanhe (int matrix_layout, char norm, char uplo, lapack_int n, const
lapack_complex_double * a, lapack_int lda);
```

Include Files

- `mkl.h`

Description

The function `?lanhe` returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a complex Hermitian matrix A .

Input Parameters

<i>norm</i>	Specifies the value to be returned by the routine: = 'M' or 'm': $val = \max(\text{abs}(A_{ij}))$, largest absolute value of the matrix A. = '1' or 'O' or 'o': $val = \text{norml}(A)$, 1-norm of the matrix A (maximum column sum), = 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix A (maximum row sum), = 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix A (square root of sum of squares).
<i>uplo</i>	Specifies whether the upper or lower triangular part of the Hermitian matrix A is to be referenced. = 'U': Upper triangular part of A is referenced. = 'L': Lower triangular part of A is referenced
<i>n</i>	The order of the matrix A . $n \geq 0$. When $n = 0$, <code>?lanhe</code> is set to zero.
<i>a</i>	Array, size at least $\max(1, lda * n)$. The Hermitian matrix A. If <i>uplo</i> = 'U', the leading n-by-n upper triangular part of a contains the upper triangular part of the matrix A, and the strictly lower triangular part of a is not referenced. If <i>uplo</i> = 'L', the leading n-by-n lower triangular part of a contains the lower triangular part of the matrix A, and the strictly upper triangular part of a is not referenced.
<i>lda</i>	The leading dimension of the array a. $lda \geq \max(n, 1)$.

?lantr

Returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a trapezoidal or triangular matrix.

Syntax

```
float LAPACKE_slantr (char * norm, char * uplo, char * diag, lapack_int * m, lapack_int * n, const float * a, lapack_int * lda, float * work);

double LAPACKE_dlantr (char * norm, char * uplo, char * diag, lapack_int * m, lapack_int * n, const double * a, lapack_int * lda, double * work);
```

```
float LAPACKE_clantr (char * norm, char * uplo, char * diag, lapack_int * m, lapack_int
* n, const lapack_complex_float * a, lapack_int * lda, float * work);

double LAPACKE_zlantr (char * norm, char * uplo, char * diag, lapack_int * m,
lapack_int * n, const lapack_complex_double * a, lapack_int * lda, double * work);
```

Include Files

- mkl.h

Description

The function `?lantr` returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a trapezoidal or triangular matrix A .

Input Parameters

<i>norm</i>	Specifies the value to be returned by the routine: = 'M' or 'm': $val = \max(\text{abs}(A_{ij}))$, largest absolute value of the matrix A. = '1' or 'O' or 'o': $val = \text{norm1}(A)$, 1-norm of the matrix A (maximum column sum), = 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix A (maximum row sum), = 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix A (square root of sum of squares).
<i>uplo</i>	Specifies whether the matrix A is upper or lower trapezoidal. = 'U': Upper trapezoidal = 'L': Lower trapezoidal. Note that A is triangular instead of trapezoidal if $m = n$.
<i>diag</i>	Specifies whether or not the matrix A has unit diagonal. = 'N': Non-unit diagonal = 'U': Unit diagonal.
<i>m</i>	The number of rows of the matrix A. $m \geq 0$, and if <i>uplo</i> = 'U', $m \leq n$. When $m = 0$, <code>?lantr</code> is set to zero.
<i>n</i>	The number of columns of the matrix A. $n \geq 0$, and if <i>uplo</i> = 'L', $n \leq m$. When $n = 0$, <code>?lantr</code> is set to zero.
<i>a</i>	Array, size at least $\max(1, lda \cdot n)$ for column major and $\max(1, lda \cdot m)$ for row major layout. The trapezoidal matrix A (A is triangular if $m = n$). If <i>uplo</i> = 'U', the leading m-by-n upper trapezoidal part of the array a contains the upper trapezoidal matrix, and the strictly lower triangular part of A is not referenced.

If *uplo* = 'L', the leading *m*-by-*n* lower trapezoidal part of the array *a* contains the lower trapezoidal matrix, and the strictly upper triangular part of *A* is not referenced. Note that when *diag* = 'U', the diagonal elements of *A* are not referenced and are assumed to be one.

lda

The leading dimension of the array *a*.

lda ≥ max(*m*, 1) for column major layout and ≥max(1, *n*) for row major layout.

?lapmr

Rearranges rows of a matrix as specified by a permutation vector.

Syntax

```
lapack_int LAPACKE_slapmr (int matrix_layout, lapack_logical forwrd, lapack_int m,
lapack_int n, float* x, lapack_int ldx, lapack_int * k);
```

```
lapack_int LAPACKE_dlapmr (int matrix_layout, lapack_logical forwrd, lapack_int m,
lapack_int n, double* x, lapack_int ldx, lapack_int * k);
```

```
lapack_int LAPACKE_clapmr (int matrix_layout, lapack_logical forwrd, lapack_int m,
lapack_int n, lapack_complex_float* x, lapack_int ldx, lapack_int * k);
```

```
lapack_int LAPACKE_zlapmr (int matrix_layout, lapack_logical forwrd, lapack_int m,
lapack_int n, lapack_complex_double* x, lapack_int ldx, lapack_int * k);
```

Include Files

- mkl.h

Description

The ?lapmr routine rearranges the rows of the *m*-by-*n* matrix *X* as specified by the permutation *k*[0], *k*[1], ... , *k*[*m*-1] of the integers 1, ..., *m*.

If *forwrd* is true, forward permutation:

X(*k*[*i*-1], :) is moved to *X*(*i*, :) for *i* = 1, 2, ..., *m*.

If *forwrd* is false, backward permutation:

X(*i*, :) is moved to *X*(*k*[*i*-1], :) for *i* = 1, 2, ..., *m*.

Input Parameters

forwrd

If *forwrd* is true, forward permutation.

If *forwrd* is false, backward permutation.

m

The number of rows of the matrix *X*. *m* ≥ 0.

n

The number of columns of the matrix *X*. *n* ≥ 0.

x

Array, size at least max(1, *ldx***n*) for column major and max(1, *ldx***m*) for row major layout. On entry, the *m*-by-*n* matrix *X*.

<i>ldx</i>	The leading dimension of the array <i>X</i> , $ldx \geq \max(1, m)$ for column major layout and $ldx \geq \max(1, n)$ for row major layout.
<i>k</i>	Array, size (<i>m</i>). On entry, <i>k</i> contains the permutation vector and is used as internal workspace.

Output Parameters

<i>x</i>	On exit, <i>x</i> contains the permuted matrix <i>X</i> .
<i>k</i>	On exit, <i>k</i> is reset to its original value.

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = -1011, memory allocation error occurred.

See Also

?lapy2

Returns $\sqrt{x^2+y^2}$.

Syntax

```
floatLAPACKE_slapy2 (floatx, floaty);
doubleLAPACKE_dlapy2 (doublex, doubley);
```

Include Files

- `mkl.h`

Description

The function ?lapy2 returns $\sqrt{x^2+y^2}$, avoiding unnecessary overflow or harmful underflow.

Input Parameters

<i>x, y</i>	Specify the input values <i>x</i> and <i>y</i> .

Return Values

The function returns a value *val*.

If *val*=-1D0, the first argument was NaN.

If *val*=-2D0, the second argument was NaN.

?lapy3

Returns $\sqrt{x^2+y^2+z^2}$.

Syntax

```
floatLAPACKE_slapy3 (floatx, floaty, floatz);
```

```
doubleLAPACKE_dlapy3 (double x, double y, double z);
```

Include Files

- mkl.h

Description

The function `?lapy3` returns $\sqrt{x^2+y^2+z^2}$, avoiding unnecessary overflow or harmful underflow.

Input Parameters

x, y, z Specify the input values *x*, *y* and *z*.

Return Values

This function returns a value *val*.

If *val* = -1D0, the first argument was NaN.

If *val* = -2D0, the second argument was NaN.

If *val* = -3D0, the third argument was NaN.

?laran

Returns a random real number from a uniform distribution.

Syntax

```
float slaran (lapack_int *iseed);
double dlaran (lapack_int *iseed);
```

Description

The `?laran` routine returns a random real number from a uniform (0,1) distribution. This routine uses a multiplicative congruential method with modulus 2^{48} and multiplier 33952834046453. 48-bit integers are stored in four integer array elements with 12 bits per element. Hence the routine is portable across machines with integers of 32 bits or more.

Input Parameters

iseed Array, size 4. On entry, the seed of the random number generator. The array elements must be between 0 and 4095, and *iseed*[3] must be odd.

Output Parameters

iseed On exit, the seed is updated.

Return Values

The function returns a random number.

?larfb

Applies a block reflector or its transpose/conjugate-transpose to a general rectangular matrix.

Syntax

```
lapack_int LAPACKE_slarfb (int matrix_layout , char side , char trans , char direct ,
char storev , lapack_int m , lapack_int n , lapack_int k , const float * v ,
lapack_int ldv , const float * t , lapack_int ldt , float * c , lapack_int ldc );

lapack_int LAPACKE_dlarfb (int matrix_layout , char side , char trans , char direct ,
char storev , lapack_int m , lapack_int n , lapack_int k , const double * v ,
lapack_int ldv , const double * t , lapack_int ldt , double * c , lapack_int
ldc ); lapack_int LAPACKE_clarfb (int matrix_layout , char side , char trans , char
direct , char storev , lapack_int m , lapack_int n , lapack_int k , const
lapack_complex_float * v , lapack_int ldv , const lapack_complex_float * t , lapack_int
ldt , lapack_complex_float * c , lapack_int ldc );

lapack_int LAPACKE_zlarfb (int matrix_layout , char side , char trans , char direct ,
char storev , lapack_int m , lapack_int n , lapack_int k , const lapack_complex_double
* v , lapack_int ldv , const lapack_complex_double * t , lapack_int ldt ,
lapack_complex_double * c , lapack_int ldc );
```

Include Files

- mkl.h

Description

The real flavors of the routine ?larfb apply a real block reflector H or its transpose H^T to a real m -by- n matrix C from either left or right.

The complex flavors of the routine ?larfb apply a complex block reflector H or its conjugate transpose H^H to a complex m -by- n matrix C from either left or right.

Input Parameters

<i>side</i>	If <i>side</i> = 'L': apply H or H^T for real flavors and H or H^H for complex flavors from the left. If <i>side</i> = 'R': apply H or H^T for real flavors and H or H^H for complex flavors from the right.
<i>trans</i>	If <i>trans</i> = 'N': apply H (No transpose). If <i>trans</i> = 'C': apply H^H (Conjugate transpose). If <i>trans</i> = 'T': apply H^T (Transpose).
<i>direct</i>	Indicates how H is formed from a product of elementary reflectors If <i>direct</i> = 'F': $H = H(1) * H(2) * \dots * H(k)$ (forward) If <i>direct</i> = 'B': $H = H(k) * \dots * H(2) * H(1)$ (backward)
<i>storev</i>	Indicates how the vectors which define the elementary reflectors are stored: If <i>storev</i> = 'C': Column-wise If <i>storev</i> = 'R': Row-wise
<i>m</i>	The number of rows of the matrix C .

n	The number of columns of the matrix C .
k	The order of the matrix T (equal to the number of elementary reflectors whose product defines the block reflector).
v	The size limitations depend on values of parameters $storev$ and $side$ as described in the following table:

	$storev = C$		$storev = R$	
	$side = L$	$side = R$	$side = L$	$side = R$
Column major	$\max(1, ldv * k)$	$\max(1, ldv * k)$	$\max(1, ldv * m)$	$\max(1, ldv * n)$
Row major	$\max(1, ldv * m)$	$\max(1, ldv * n)$	$\max(1, ldv * k)$	$\max(1, ldv * k)$

The matrix v . See *Application Notes* below.

ldv	The leading dimension of the array v . It should satisfy the following conditions:

	$storev = C$		$storev = R$	
	$side = L$	$side = R$	$side = L$	$side = R$
Column major	$\max(1, m)$	$\max(1, n)$	$\max(1, k)$	$\max(1, k)$
Row major	$\max(1, k)$	$\max(1, k)$	$\max(1, m)$	$\max(1, n)$

t	Array, size at least $\max(1, ldt * k)$. Contains the triangular k -by- k matrix T in the representation of the block reflector.

ldt	The leading dimension of the array t . $ldt \geq k$.

c	Array, size at least $\max(1, ldc * n)$ for column major layout and $\max(1, ldc * m)$ for row major layout. On entry, the m -by- n matrix C .

ldc	The leading dimension of the array c . $ldc \geq \max(1, m)$ for column major layout and $ldc \geq \max(1, n)$ for row major layout.

Output Parameters

c	On exit, c is overwritten by the product of the following: $H * C$, or $H^T * C$, or $C * H$, or $C * H^T$ for real flavors $H * C$, or $H^H * C$, or $C * H$, or $C * H^H$ for complex flavors

```
lapack_int LAPACKE_zlarfg (lapack_int n , lapack_complex_double * alpha ,
lapack_complex_double * x , lapack_int incx , lapack_complex_double * tau );
```

Include Files

- mkl.h

Description

The routine `?larfg` generates a real/complex elementary reflector H of order n , such that

$$H^* \begin{bmatrix} \alpha \\ x \end{bmatrix} = \begin{bmatrix} \beta \\ 0 \end{bmatrix}, \quad H^T H = I, \quad \text{for real flavors and}$$

$$H^H \begin{bmatrix} \alpha \\ x \end{bmatrix} = \begin{bmatrix} \beta \\ 0 \end{bmatrix}, \quad H^H H = I, \quad \text{for complex flavors,}$$

where α and β are scalars (with β real for all flavors), and x is an $(n-1)$ -element real/complex vector. H is represented in the form

$$H = I - \tau \begin{bmatrix} 1 \\ v \end{bmatrix} \begin{bmatrix} 1 & v^T \end{bmatrix} \quad \text{for real flavors and}$$

$$H = I - \tau \begin{bmatrix} 1 \\ v \end{bmatrix} \begin{bmatrix} 1 & v^H \end{bmatrix} \quad \text{for complex flavors,}$$

where τ is a real/complex scalar and v is a real/complex $(n-1)$ -element vector, respectively. Note that for `clarfg/zlarfg`, H is not Hermitian.

If the elements of x are all zero (and, for complex flavors, α is real), then $\tau = 0$ and H is taken to be the unit matrix.

Otherwise, $1 \leq \tau \leq 2$ (for real flavors), or

$1 \leq \text{Re}(\tau) \leq 2$ and $|\text{Im}(\tau)| \leq 1$ (for complex flavors).

Input Parameters

n	The order of the elementary reflector.
α	
x	Array, size $(1+(n-2)*\text{abs}(\text{incx}))$. On entry, the vector x .
incx	The increment between elements of x . $\text{incx} > 0$.

Output Parameters

α	On exit, it is overwritten with the value β .
x	On exit, it is overwritten with the vector v .
τ	

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -2, *alpha* is NaN

If *info* = -3, array *x* contains NaN components.

?larft

Forms the triangular factor *T* of a block reflector $H = I - V^* T^* V^* H$.

Syntax

```
lapack_int LAPACKE_slarft (int matrix_layout , char direct , char storev , lapack_int
n , lapack_int k , const float * v , lapack_int ldv , const float * tau , float * t ,
lapack_int ldt );
```

```
lapack_int LAPACKE_dlarft (int matrix_layout , char direct , char storev , lapack_int
n , lapack_int k , const double * v , lapack_int ldv , const double * tau , double *
t , lapack_int ldt );
```

```
lapack_int LAPACKE_clarft (int matrix_layout , char direct , char storev , lapack_int
n , lapack_int k , const lapack_complex_float * v , lapack_int ldv , const
lapack_complex_float * tau , lapack_complex_float * t , lapack_int ldt );
```

```
lapack_int LAPACKE_zlarft (int matrix_layout , char direct , char storev , lapack_int
n , lapack_int k , const lapack_complex_double * v , lapack_int ldv , const
lapack_complex_double * tau , lapack_complex_double * t , lapack_int ldt );
```

Include Files

- mkl.h

Description

The routine ?larft forms the triangular factor *T* of a real/complex block reflector *H* of order *n*, which is defined as a product of *k* elementary reflectors.

If *direct* = 'F', $H = H(1) * H(2) * \dots * H(k)$ and *T* is upper triangular;

If *direct* = 'B', $H = H(k) * \dots * H(2) * H(1)$ and *T* is lower triangular.

If *storev* = 'C', the vector which defines the elementary reflector *H*(*i*) is stored in the *i*-th column of the array *v*, and $H = I - V^* T^* V^T$ (for real flavors) or $H = I - V^* T^* V^H$ (for complex flavors) .

If *storev* = 'R', the vector which defines the elementary reflector *H*(*i*) is stored in the *i*-th row of the array *v*, and $H = I - V^T T^* V$ (for real flavors) or $H = I - V^H T^* V$ (for complex flavors).

Input Parameters

direct

Specifies the order in which the elementary reflectors are multiplied to form the block reflector:

= 'F': $H = H(1) * H(2) * \dots * H(k)$ (forward)

= 'B': $H = H(k) * \dots * H(2) * H(1)$ (backward)

storev

Specifies how the vectors which define the elementary reflectors are stored (see also *Application Notes* below):

= 'C': column-wise

= 'R': row-wise.

n The order of the block reflector H . $n \geq 0$.

k The order of the triangular factor T (equal to the number of elementary reflectors). $k \geq 1$.

v The size limitations depend on values of parameters *storev* and *side* as described in the following table:

	<i>storev</i> = C	<i>storev</i> = R
Column major	$\max(1, ldv * k)$	$\max(1, ldv * n)$
Row major	$\max(1, ldv * n)$	$\max(1, ldv * k)$

The matrix v . See *Application Notes* below.

ldv The leading dimension of the array v .

If *storev* = 'C', $ldv \geq \max(1, n)$ for column major and $ldv \geq \max(1, k)$ for row major;

if *storev* = 'R', $ldv \geq k$ for column major and $ldv \geq \max(1, n)$ for row major.

τ Array, size (k) . $\tau[i-1]$ must contain the scalar factor of the elementary reflector $H(i)$.

ldt The leading dimension of the output array t . $ldt \geq k$.

Output Parameters

t Array, size $ldt * k$. The k -by- k triangular factor T of the block reflector. If *direct* = 'F', T is upper triangular; if *direct* = 'B', T is lower triangular. The rest of the array is not used.

v The matrix V .

Application Notes

The shape of the matrix V and the storage of the vectors which define the $H(i)$ is best illustrated by the following example with $n = 5$ and $k = 3$. The elements equal to 1 are not stored; the corresponding array elements are modified but restored on exit. The rest of the array is not used.

- $H = I - \tau v v^T$, where τ is a real scalar and v is a real vector.
- $H = I - \tau v v^H$, where τ is a complex scalar and v is a complex vector.

If $\tau = 0$, then H is taken to be the unit matrix.

Input Parameters

<i>side</i>	If <i>side</i> = 'L': form H^*C If <i>side</i> = 'R': form C^*H.
<i>m</i>	The number of rows of the matrix C .
<i>n</i>	The number of columns of the matrix C .
<i>v</i>	Array, size (<i>m</i>) if <i>side</i> = 'L' or (<i>n</i>) if <i>side</i> = 'R'. The vector v in the representation of H.
<i>tau</i>	The value τ in the representation of H .
<i>c</i>	Array, size at least $\max(1, ldc*n)$ for column major layout and $\max(1, ldc*m)$ for row major layout. On entry, the m -by- n matrix C .
<i>ldc</i>	The leading dimension of the array <i>c</i> . $lda \geq (1, m)$.
<i>work</i>	Workspace array, size (<i>n</i>) if <i>side</i> = 'L' or (<i>m</i>) if <i>side</i> = 'R'. <i>work</i> is not referenced if H has order < 11.

Output Parameters

<i>c</i>	On exit, <i>C</i> is overwritten by the matrix H^*C if <i>side</i> = 'L', or C^*H if <i>side</i> = 'R'.

?large

Pre- and post-multiplies a real general matrix with a random orthogonal matrix.

Syntax

```
void slarge (lapack_int *n, float *a, lapack_int *lda, lapack_int *iseed, float * work,
lapack_int *info);

void dlarge (lapack_int *n, double *a, lapack_int *lda, lapack_int *iseed, double *
work, lapack_int *info);

void clarge (lapack_int *n, lapack_complex *a, lapack_int *lda, lapack_int *iseed,
lapack_complex * work, lapack_int *info);

void zlarge (lapack_int *n, lapack_complex_double *a, lapack_int *lda, lapack_int
*iseed, lapack_complex_double * work, lapack_int *info);
```

Include Files

- `mk1.h`

Description

The routine `?larnd` pre- and post-multiplies a general n -by- n matrix A with a random orthogonal or unitary matrix: $A = U * D * U^T$.

Input Parameters

n	The order of the matrix A . $n \geq 0$
a	Array, size lda by n . On entry, the original n -by- n matrix A .
lda	The leading dimension of the array a . $lda \geq n$.
$iseed$	Array, size 4. On entry, the seed of the random number generator. The array elements must be between 0 and 4095, and $iseed[3]$ must be odd.
$work$	Workspace array, size $2*n$.

Output Parameters

a	On exit, A is overwritten by $U * A * U'$ for some random orthogonal matrix U .
$iseed$	On exit, the seed is updated.
$info$	If $info = 0$, the execution is successful. If $info < 0$, the i -th parameter had an illegal value.

?larnd

Returns a random real number from a uniform or normal distribution.

Syntax

```
float slarnd (lapack_int *idist, lapack_int *iseed);
double dlarnd (lapack_int *idist, lapack_int *iseed);
```

The data types for complex variations depend on whether or not the application links with Gnu Fortran (gfortran) libraries.

For non-gfortran (`libmk1_intel_*`) interface libraries:

```
void clarnd (lapack_complex_float *res, lapack_int *idist, lapack_int *iseed);
void zlarnd (lapack_complex_double *res, lapack_int *idist, lapack_int *iseed);
```

For gfortran (`libmk1_gf_*`) interface libraries:

```
lapack_complex_float clarnd (lapack_int *idist, lapack_int *iseed);
lapack_complex_double zlarnd (lapack_int *idist, lapack_int *iseed);
```

To understand the difference between the non-gfortran and gfortran interfaces and when to use each of them, see Dynamic Libraries in the lib/intel64 Directory in the *Intel MKL User's Guide*.

Include Files

- `mkl.h`

Description

The routine `?larnd` returns a random number from a uniform or normal distribution.

Input Parameters

<i>idist</i>	Specifies the distribution of the random numbers. For <code>slarnd</code> and <code>dlanrd</code> : = 1: uniform (0,1) = 2: uniform (-1,1) = 3: normal (0,1). For <code>clarnd</code> and <code>zlanrd</code> : = 1: real and imaginary parts each uniform (0,1) = 2: real and imaginary parts each uniform (-1,1) = 3: real and imaginary parts each normal (0,1) = 4: uniformly distributed on the disc $\text{abs}(z) \leq 1$ = 5: uniformly distributed on the circle $\text{abs}(z) = 1$
<i>iseed</i>	Array, size 4. On entry, the seed of the random number generator. The array elements must be between 0 and 4095, and <code>iseed[3]</code> must be odd.

Output Parameters

<i>iseed</i>	On exit, the seed is updated.

Return Values

The function returns a random number (for complex variations `libmkl_gf_*` interface layer/libraries return the result as the parameter `res`).

?larnv

Returns a vector of random numbers from a uniform or normal distribution.

Syntax

```
lapack_int LAPACKE_slarnv (lapack_int idist , lapack_int * iseed , lapack_int n , float
* x );

lapack_int LAPACKE_dlarnd (lapack_int idist , lapack_int * iseed , lapack_int n ,
double * x );

lapack_int LAPACKE_clarnv (lapack_int idist , lapack_int * iseed , lapack_int n ,
lapack_complex_float * x );

lapack_int LAPACKE_zlarnd (lapack_int idist , lapack_int * iseed , lapack_int n ,
lapack_complex_double * x );
```

Include Files

- `mk1.h`

Description

The routine `?larlv` returns a vector of n random real/complex numbers from a uniform or normal distribution.

This routine calls the auxiliary routine `?laruv` to generate random real numbers from a uniform (0,1) distribution, in batches of up to 128 using vectorisable code. The Box-Muller method is used to transform numbers from a uniform to a normal distribution.

Input Parameters

<i>idist</i>	Specifies the distribution of the random numbers: for <code>slarnv</code> and <code>dlarnv</code> : = 1: uniform (0,1) = 2: uniform (-1,1) = 3: normal (0,1). for <code>clarnv</code> and <code>zlarnv</code> : = 1: real and imaginary parts each uniform (0,1) = 2: real and imaginary parts each uniform (-1,1) = 3: real and imaginary parts each normal (0,1) = 4: uniformly distributed on the disc $\text{abs}(z) < 1$ = 5: uniformly distributed on the circle $\text{abs}(z) = 1$
<i>iseed</i>	Array, size (4). On entry, the seed of the random number generator; the array elements must be between 0 and 4095, and <i>iseed</i> (4) must be odd.
<i>n</i>	The number of random numbers to be generated.

Output Parameters

<i>x</i>	Array, size (<i>n</i>). The generated random numbers.
<i>iseed</i>	On exit, the seed is updated.

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

?laror

Pre- or post-multiplies an m-by-n matrix by a random orthogonal/unitary matrix.

Syntax

```
void slaror (char *side, char *init, lapack_int *m, lapack_int *n, float *a, lapack_int
*lda, lapack_int *iseed, float *x, lapack_int *info);
```

```
void dlaror (char *side, char *init, lapack_int *m, lapack_int *n, double *a,
lapack_int *lda, lapack_int *iseed, double *x, lapack_int *info);

void claror (char *side, char *init, lapack_int *m, lapack_int *n, lapack_complex *a,
lapack_int *lda, lapack_int *iseed, lapack_complex *x, lapack_int *info);

void zlaror (char *side, char *init, lapack_int *m, lapack_int *n,
lapack_complex_double *a, lapack_int *lda, lapack_int *iseed, lapack_complex_double *x,
lapack_int *info);
```

Include Files

- mkl.h

Description

The routine `?laror` pre- or post-multiplies an m -by- n matrix A by a random orthogonal or unitary matrix U , overwriting A . A may optionally be initialized to the identity matrix before multiplying by U . U is generated using the method of G.W. Stewart (SIAM J. Numer. Anal. 17, 1980, 403-409).

Input Parameters

<i>side</i>	Specifies whether A is multiplied by U on the left or right. for <code>slaror</code> and <code>dlaror</code>: If <i>side</i> = 'L', multiply A on the left (premultiply) by U. If <i>side</i> = 'R', multiply A on the right (postmultiply) by U^T. If <i>side</i> = 'C' or 'T', multiply A on the left by U and the right by U^T. for <code>claror</code> and <code>zlaror</code>: If <i>side</i> = 'L', multiply A on the left (premultiply) by U. If <i>side</i> = 'R', multiply A on the right (postmultiply) by $UC^>$. If <i>side</i> = 'C', multiply A on the left by U and the right by $UC^>$. If <i>side</i> = 'T', multiply A on the left by U and the right by U^T.
<i>init</i>	Specifies whether or not a should be initialized to the identity matrix. If <i>init</i> = 'I', initialize a to (a section of) the identity matrix before applying U. If <i>init</i> = 'N', no initialization. Apply U to the input matrix A. <i>init</i> = 'I' generates square or rectangular orthogonal matrices: For $m = n$ and <i>side</i> = 'L' or 'R', the rows and the columns are orthogonal to each other. For rectangular matrices where $m < n$: • If <i>side</i> = 'R', <code>?laror</code> produces a dense matrix in which rows are orthogonal and columns are not. • If <i>side</i> = 'L', <code>?laror</code> produces a matrix in which rows are orthogonal, first m columns are orthogonal, and remaining columns are zero. For rectangular matrices where $m > n$: • If <i>side</i> = 'L', <code>?laror</code> produces a dense matrix in which columns are orthogonal and rows are not.

- If *side* = 'R', `?laror` produces a matrix in which columns are orthogonal, first *m* rows are orthogonal, and remaining rows are zero.

m The number of rows of *A*.

n The number of columns of *A*.

a Array, size *lda* by *n*.

lda The leading dimension of the array *a*.
 $lda \geq \max(1, m)$.

iseed Array, size (4).
 On entry, specifies the seed of the random number generator. The array elements must be between 0 and 4095; if not they are reduced mod 4096. Also, *iseed*[3] must be odd.

x Workspace array, size $(3 * \max(m, n))$.

Value of <i>side</i>	Length of workspace
'L'	$2*m + n$
'R'	$2*n + m$
'C' or 'T'	$3*n$

Output Parameters

a On exit, overwritten
 by *UA* (if *side* = 'L'),
 by *AU* (if *side* = 'R'),
 by *UAU^T* (if *side* = 'C' or 'T').

iseed The values of *iseed* are changed on exit, and can be used in the next call to continue the same random number sequence.

info Array, size (4).
 For `slaror` and `dlaror`:
 If *info* = 0, the execution is successful.
 If *info* < 0, the *i*-th parameter had an illegal value.
 If *info* = 1, the random numbers generated by `?laror` are bad.
 For `claror` and `zlaror`:
 If *info* = 0, the execution is successful.
 If *info* = -1, *side* is not 'L', 'R', 'C', or 'T'.
 If *info* = -3, if *m* is negative.
 If *info* = -4, if *m* is negative or if *side* is 'C' or 'T' and *n* is not equal to *m*.
 If *info* = -6, if *lda* is less than *m*.

?larot

Applies a Givens rotation to two adjacent rows or columns.

Syntax

```
void slarot (lapack_logical *lrows, lapack_logical *ileft, lapack_logical *iright,
lapack_int *nl, float *c, float *s, float *a, lapack_int *lda, float *xleft, float
*xright);

void dlarot (lapack_logical *lrows, lapack_logical *ileft, lapack_logical *iright,
lapack_int *nl, double *c, double *s, double *a, lapack_int *lda, double *xleft,
double *xright);

void clarot (lapack_logical *lrows, lapack_logical *ileft, lapack_logical *iright,
lapack_int *nl, lapack_complex *c, lapack_complex *s, lapack_complex *a, lapack_int
*lda, lapack_complex *xleft, lapack_complex *xright);

void zlarot (lapack_logical *lrows, lapack_logical *ileft, lapack_logical *iright,
lapack_int *nl, lapack_complex_double *c, lapack_complex_double *s,
lapack_complex_double *a, lapack_int *lda, lapack_complex_double *xleft,
lapack_complex_double *xright);
```

Include Files

- mkl.h

Description

The routine ?larot applies a Givens rotation to two adjacent rows or columns, where one element of the first or last column or row is stored in some format other than GE so that elements of the matrix may be used or modified for which no array element is provided.

One example is a symmetric matrix in SB format (bandwidth = 4), for which *uplo* = 'L'. Two adjacent rows will have the format:

```
row j :      C > C > C > C > C > . . . .
row j + 1 :  C > C > C > C > C > . . . .
```

'*' indicates elements for which storage is provided.

'.' indicates elements for which no storage is provided, but are not necessarily zero; their values are determined by symmetry.

' ' indicates elements which are required to be zero, and have no storage provided.

Those columns which have two '*' entries can be handled by srot (for slarot and clarot), or by drot (for dlarot and zlarot).

Those columns which have no '*' entries can be ignored, since as long as the Givens rotations are carefully applied to preserve symmetry, their values are determined.

Those columns which have one '*' have to be handled separately, by using separate variables *p* and *q* :

```
row j :      C > C > C > C > C > p. . . .
row j + 1 :  q C > C > C > C > C > . . . .
```

If element *p* is set correctly, ?larot rotates the column and sets *p* to its new value. The next call to ?larot rotates columns *j* and *j* + 1, and restore symmetry. The element *q* is zero at the beginning, and non-zero after the rotation. Later, rotations would presumably be chosen to zero *q* out.

Typical Calling Sequences: rotating the *i* -th and (*i* + 1) -st rows.

Input Parameters

<i>lrows</i>	If <i>lrows</i> = 1, <i>?larot</i> rotates two rows. If <i>lrows</i> = 0, <i>?larot</i> rotates two columns.
<i>lleft</i>	If <i>lleft</i> = 1, <i>xleft</i> is used instead of the corresponding element of <i>a</i> for the first element in the second row (if <i>lrows</i> = 0) or column (if <i>lrows</i>=1). If <i>lleft</i> = 0, the corresponding element of <i>a</i> is used.
<i>lright</i>	If <i>lleft</i> = 1, <i>xright</i> is used instead of the corresponding element of <i>a</i> for the first element in the second row (if <i>lrows</i> = 0) or column (if <i>lrows</i>=1). If <i>lright</i> = 0, the corresponding element of <i>a</i> is used.
<i>nl</i>	The length of the rows (if <i>lrows</i>=1) or columns (if <i>lrows</i>=1) to be rotated. If <i>xleft</i> or <i>xright</i> are used, the columns or rows they are in should be included in <i>nl</i>, e.g., if <i>lleft</i> = <i>lright</i> = 1, then <i>nl</i> must be at least 2. The number of rows or columns to be rotated exclusive of those involving <i>xleft</i> and/or <i>xright</i> may not be negative, i.e., <i>nl</i> minus how many of <i>lleft</i> and <i>lright</i> are 1 must be at least zero; if not, <i>xerbla</i> is called.
<i>c, s</i>	Specify the Givens rotation to be applied. If <i>lrows</i> = 1, then the matrix $\begin{bmatrix} c & s \\ -s & c \end{bmatrix}$ is applied from the left. If <i>lrows</i> = 0, then the transpose thereof is applied from the right.
<i>a</i>	The array containing the rows or columns to be rotated. The first element of <i>a</i> should be the upper left element to be rotated.
<i>lda</i>	The "effective" leading dimension of <i>a</i>. If <i>a</i> contains a matrix stored in GE or SY format, then this is just the leading dimension of <i>A</i>. If <i>a</i> contains a matrix stored in band (GB or SB) format, then this should be one less than the leading dimension used in the calling routine. Thus, if <i>a</i> in <i>?larot</i> is of size <i>lda</i>*<i>n</i>, then <i>a</i>[(<i>j</i> - 1)*<i>lda</i>] would be the <i>j</i>-th element in the first of the two rows to be rotated, and <i>a</i>[(<i>j</i> - 1)*<i>lda</i> + 1] would be the <i>j</i>-th in the second, regardless of how the array may be stored in the calling routine. <i>a</i> cannot be dimensioned, because for band format the row number may exceed <i>lda</i>, which is not legal FORTRAN. If <i>lrows</i> = 1, then <i>lda</i> must be at least 1, otherwise it must be at least <i>nl</i> minus the number of 1 values in <i>xleft</i> and <i>xright</i>.

xleft If *lrows* = 1, *xleft* is used and modified instead of *a*[1] (if *lrows* = 1) or *a*[*lda* + 1] (if *lrows* = 0).

xright If *lright* = 1, *xright* is used and modified instead of *a*[(*nl* - 1)**lda*] (if *lrows* = 1) or *a*[*nl* - 1] (if *lrows* = 0).

Output Parameters

a On exit, modified array *A*.

?lartgp

Generates a plane rotation.

Syntax

```
lapack_int LAPACKE_slartgp (float f, floatg, float* cs, float* sn, float* r);
lapack_int LAPACKE_dlartgp (doublef, doubleg, double* cs, double* sn, double* r);
```

Include Files

- mkl.h

Description

The routine generates a plane rotation so that

$$\begin{bmatrix} cs & sn \\ -sn & cs \end{bmatrix} \cdot \begin{bmatrix} f \\ g \end{bmatrix} = \begin{bmatrix} r \\ 0 \end{bmatrix}$$

where $cs^2 + sn^2 = 1$

This is a slower, more accurate version of the BLAS Level 1 routine *?rotg*, except for the following differences:

- *f* and *g* are unchanged on return.
- If *g*=0, then *cs*=(+/-)1 and *sn*=0.
- If *f*=0 and *g*≠ 0, then *cs*=0 and *sn*=(+/-)1.

The sign is chosen so that $r \geq 0$.

Input Parameters

f, g The first and second component of the vector to be rotated.

Output Parameters

cs The cosine of the rotation.

sn The sine of the rotation.

r The nonzero component of the rotated vector.

Return Values

If `info = 0`, the execution is successful.

If `info = -1`, `f` is NaN.

If `info = -2`, `g` is NaN.

See Also

[cblas_?rotg](#)

[?lartgs](#)

?lartgs

Generates a plane rotation designed to introduce a bulge in implicit QR iteration for the bidiagonal SVD problem.

Syntax

```
lapack_int LAPACKE_slartgs (floatx, floaty, floatsigma, float* cs, float* sn);
lapack_int LAPACKE_dlartgs (doublex, doubley, doublesigma, double* cs, double* sn);
```

Include Files

- `mkl.h`

Description

The routine generates a plane rotation designed to introduce a bulge in Golub-Reinsch-style implicit QR iteration for the bidiagonal SVD problem. `x` and `y` are the top-row entries, and `sigma` is the shift. The computed `cs` and `sn` define a plane rotation that satisfies the following:

$$\begin{bmatrix} cs & sn \\ -sn & cs \end{bmatrix} \cdot \begin{bmatrix} x^2 - sigma \\ x * y \end{bmatrix} = \begin{bmatrix} r \\ 0 \end{bmatrix}$$

with r nonnegative.

If $x^2 - sigma$ and $x * y$ are 0, the rotation is by $\pi/2$

Input Parameters

`x, y` The (1,1) and (1,2) entries of an upper bidiagonal matrix, respectively.

`sigma` Shift

Output Parameters

`cs` The cosine of the rotation.

`sn` The sine of the rotation.

Return Values

If `info = 0`, the execution is successful.

If `info = - 1`, `x` is NaN.

If `info = - 2`, `y` is NaN.

If *info* = - 3, *sigma* is NaN.

See Also

[?lartgp](#)

?laset

Initializes the off-diagonal elements and the diagonal elements of a matrix to given values.

Syntax

```
lapack_int LAPACKE_slaset (int matrix_layout , char uplo , lapack_int m , lapack_int
n , float alpha , float beta , float * a , lapack_int lda );

lapack_int LAPACKE_dlaset (int matrix_layout , char uplo , lapack_int m , lapack_int
n , double alpha , double beta , double * a , lapack_int lda );

lapack_int LAPACKE_claset (int matrix_layout , char uplo , lapack_int m , lapack_int
n , lapack_complex_float alpha , lapack_complex_float beta , lapack_complex_float * a ,
lapack_int lda );

lapack_int LAPACKE_zlaset (int matrix_layout , char uplo , lapack_int m , lapack_int
n , lapack_complex_double alpha , lapack_complex_double beta , lapack_complex_double *
a , lapack_int lda );
```

Include Files

- mkl.h

Description

The routine initializes an *m*-by-*n* matrix *A* to *beta* on the diagonal and *alpha* on the off-diagonals.

Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>uplo</i>	Specifies the part of the matrix <i>A</i> to be set. If <i>uplo</i> = 'U', upper triangular part is set; the strictly lower triangular part of <i>A</i> is not changed. If <i>uplo</i> = 'L': lower triangular part is set; the strictly upper triangular part of <i>A</i> is not changed. Otherwise: All of the matrix <i>A</i> is set.
<i>m</i>	The number of rows of the matrix <i>A</i> . $m \geq 0$.
<i>n</i>	The number of columns of the matrix <i>A</i> . $n \geq 0$.
<i>alpha</i> , <i>beta</i>	The constants to which the off-diagonal and diagonal elements are to be set, respectively.
<i>a</i>	Array, size at least $\max(1, lda*n)$ for column major and $\max(1, lda*m)$ for row major layout.

The array a contains the m -by- n matrix A .

lda

The leading dimension of the array a .

$lda \geq \max(1, m)$ for column major layout and $lda \geq \max(1, n)$ for row major layout.

Output Parameters

a

On exit, the leading m -by- n submatrix of A is set as follows:

if $uplo = 'U'$, $A_{ij} = \alpha$, $1 \leq i \leq j-1$, $1 \leq j \leq n$,

if $uplo = 'L'$, $A_{ij} = \alpha$, $j+1 \leq i \leq m$, $1 \leq j \leq n$,

otherwise, $A_{ij} = \alpha$, $1 \leq i \leq m$, $1 \leq j \leq n$, $i \neq j$,

and, for all $uplo$, $A_{ij} = \beta$, $1 \leq i \leq \min(m, n)$.

Return Values

This function returns a value $info$.

If $info = 0$, the execution is successful.

If $info = i < 0$, the i -th parameter had an illegal value.

If $info = -1011$, memory allocation error occurred.

?lasrt

Sorts numbers in increasing or decreasing order.

Syntax

```
lapack_int LAPACKE_slasrt (char id , lapack_int n , float * d );
```

```
lapack_int LAPACKE_dlasrt (char id , lapack_int n , double * d );
```

Include Files

- mkl.h

Description

The routine ?lasrt sorts the numbers in d in increasing order (if $id = 'I'$) or in decreasing order (if $id = 'D'$). It uses Quick Sort, reverting to Insertion Sort on arrays of size ≤ 20 . Dimension of `stack` limits n to about 2^{32} .

Input Parameters

id

= 'I': sort d in increasing order;

= 'D': sort d in decreasing order.

n

The length of the array d .

d

On entry, the array to be sorted.

Output Parameters

d On exit, *d* has been sorted into increasing order
 $(d[0] \leq d[1] \leq \dots \leq d[n-1])$ or into decreasing order
 $(d[0] \geq d[1] \geq \dots \geq d[n-1])$, depending on *id*.

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* < 0, the *i*-th parameter had an illegal value.

?laswp

Performs a series of row interchanges on a general rectangular matrix.

Syntax

```
lapack_int LAPACKE_slaswp (int matrix_layout , lapack_int n , float * a , lapack_int
lda , lapack_int k1 , lapack_int k2 , const lapack_int * ipiv , lapack_int incx );

lapack_int LAPACKE_dlaswp (int matrix_layout , lapack_int n , double * a , lapack_int
lda , lapack_int k1 , lapack_int k2 , const lapack_int * ipiv , lapack_int incx );

lapack_int LAPACKE_claswp (int matrix_layout , lapack_int n , lapack_complex_float *
a , lapack_int lda , lapack_int k1 , lapack_int k2 , const lapack_int * ipiv ,
lapack_int incx );

lapack_int LAPACKE_zlaswp (int matrix_layout , lapack_int n , lapack_complex_double *
a , lapack_int lda , lapack_int k1 , lapack_int k2 , const lapack_int * ipiv ,
lapack_int incx );
```

Include Files

- mkl.h

Description

The routine performs a series of row interchanges on the matrix *A*. One row interchange is initiated for each of rows *k1* through *k2* of *A*.

Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>n</i>	The number of columns of the matrix <i>A</i> .
<i>a</i>	Array, size $\max(1, lda \cdot n)$ for column major and $\max(1, lda \cdot mm)$ for row major layout. Here <i>mm</i> is not less than maximum of values $ipiv[k1-1+j* incx]$, $0 \leq j < k2-k1$. Array <i>a</i> contains the <i>m</i> -by- <i>n</i> matrix <i>A</i> .
<i>lda</i>	The leading dimension of the array <i>a</i> .

<i>k1</i>	The first element of <i>ipiv</i> for which a row interchange will be done.
<i>k2</i>	The last element of <i>ipiv</i> for which a row interchange will be done.
<i>ipiv</i>	Array, size $k1 + (k2 - k1) * incx$. The vector of pivot indices. Only the elements in positions <i>k1</i> through <i>k2</i> of <i>ipiv</i> are accessed. $ipiv(k) = l$ implies rows <i>k</i> and <i>l</i> are to be interchanged.
<i>incx</i>	The increment between successive values of <i>ipiv</i> . If <i>ipiv</i> is negative, the pivots are applied in reverse order.

Output Parameters

<i>a</i>	On exit, the permuted matrix.

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = -1011, memory allocation error occurred.

?latm1

Computes the entries of a matrix as specified.

Syntax

```
void slatm1 (lapack_int *mode, *cond, lapack_int *irsign, lapack_int *idist, lapack_int
*iseed, float *d, lapack_int *n, lapack_int *info);
void dlatm1 (lapack_int *mode, *cond, lapack_int *irsign, lapack_int *idist, lapack_int
*iseed, double *d, lapack_int *n, lapack_int *info);
void clatm1 (lapack_int *mode, *cond, lapack_int *irsign, lapack_int *idist, lapack_int
*iseed, lapack_complex *d, lapack_int *n, lapack_int *info);
void zlatm1 (lapack_int *mode, *cond, lapack_int *irsign, lapack_int *idist, lapack_int
*iseed, lapack_complex_double *d, lapack_int *n, lapack_int *info);
```

Include Files

- mkl.h

Description

The ?latm1 routine computes the entries of $D(1..n)$ as specified by *mode*, *cond* and *irsign*. *idist* and *iseed* determine the generation of random numbers.

?latm1 is called by slatmr (for slatm1 and dlatm1), and by clatmr (for clatm1 and zlatm1) to generate random test matrices for LAPACK programs.

Input Parameters

<i>mode</i>	On entry describes how <i>d</i> is to be computed: <i>mode</i> = 0 means do not change <i>d</i>. <i>mode</i> = 1 sets $d[0] = 1$ and $d[1:n - 1] = 1.0/cond$ <i>mode</i> = 2 sets $d[0:n - 2] = 1$ and $d[n - 1] = 1.0/cond$ <i>mode</i> = 3 sets $d[i - 1] = cond^{-(i-1)/(n-1)}$ <i>mode</i> = 4 sets $d[i - 1] = 1 - (i-1)/(n-1) * (1 - 1/cond)$ <i>mode</i> = 5 sets <i>d</i> to random numbers in the range $(1/cond, 1)$ such that their logarithms are uniformly distributed. <i>mode</i> = 6 sets <i>d</i> to random numbers from same distribution as the rest of the matrix. <i>mode</i> < 0 has the same meaning as $abs(mode)$, except that the order of the elements of <i>d</i> is reversed. Thus if <i>mode</i> is positive, <i>d</i> has entries ranging from 1 to $1/cond$, if negative, from $1/cond$ to 1.
<i>cond</i>	On entry, used as described under <i>mode</i> above. If used, it must be ≥ 1 .
<i>irsign</i>	On entry, if <i>mode</i> is not -6, 0, or 6, determines sign of entries of <i>d</i>. If <i>irsign</i> = 0, entries of <i>d</i> are unchanged. If <i>irsign</i> = 1, each entry of <i>d</i> is multiplied by a random complex number uniformly distributed with absolute value 1.
<i>idist</i>	Specifies the distribution of the random numbers. For <i>slatml</i> and <i>dlatml</i>: = 1: uniform (0,1) = 2: uniform (-1,1) = 3: normal (0,1) For <i>clatml</i> and <i>zlatml</i>: = 1: real and imaginary parts each uniform (0,1) = 2: real and imaginary parts each uniform (-1,1) = 3: real and imaginary parts each normal (0,1) = 4: complex number uniform in disk(0, 1)
<i>iseed</i>	Array, size (4). Specifies the seed of the random number generator. The random number generator uses a linear congruential sequence limited to small integers, and so should produce machine independent random numbers. The values of <i>iseed</i>[3] are changed on exit, and can be used in the next call to ?latml to continue the same random number sequence.
<i>d</i>	Array, size <i>n</i> .
<i>n</i>	Number of entries of <i>d</i> .

Output Parameters

<i>iseed</i>	On exit, the seed is updated.
<i>d</i>	On exit, <i>d</i> is updated, unless <i>mode</i> = 0.
<i>info</i>	If <i>info</i> = 0, the execution is successful. If <i>info</i> = -1, <i>mode</i> is not in range -6 to 6. If <i>info</i> = -2, <i>mode</i> is neither -6, 0 nor 6, and <i>irsign</i> is neither 0 nor 1. If <i>info</i> = -3, <i>mode</i> is neither -6, 0 nor 6 and <i>cond</i> is less than 1. If <i>info</i> = -4, <i>mode</i> equals 6 or -6 and <i>idist</i> is not in range 1 to 4. If <i>info</i> = -7, <i>n</i> is negative.

?latm2

Returns an entry of a random matrix.

Syntax

```
float slatm2 (lapack_int *m, lapack_int *n, lapack_int *i, lapack_int *j, lapack_int
*kl, lapack_int *ku, lapack_int *idist, lapack_int *iseed, float *d, lapack_int
*igrade, float *dl, float *dr, lapack_int *ipvtng, lapack_int *iwork, float *sparse);

double dlatm2 (lapack_int *m, lapack_int *n, lapack_int *i, lapack_int *j, lapack_int
*kl, lapack_int *ku, lapack_int *idist, lapack_int *iseed, double *d, lapack_int
*igrade, double *dl, double *dr, lapack_int *ipvtng, lapack_int *iwork, double
*sparse);
```

The data types for complex variations depend on whether or not the application links with Gnu Fortran (gfortran) libraries.

For non-gfortran (libmkl_intel_*) interface libraries:

```
void clatm2 (lapack_complex_float *res, lapack_int *m, lapack_int *n, lapack_int *i,
lapack_int *j, lapack_int *kl, lapack_int *ku, lapack_int *idist, lapack_int *iseed,
lapack_complex_float *d, lapack_int *igrade, lapack_complex_float *dl,
lapack_complex_float *dr, lapack_int *ipvtng, lapack_int *iwork, float *sparse);

void zlatm2 (lapack_complex_double *res, lapack_int *m, lapack_int *n, lapack_int *i,
lapack_int *j, lapack_int *kl, lapack_int *ku, lapack_int *idist, lapack_int *iseed,
lapack_complex_double *d, lapack_int *igrade, lapack_complex_double *dl,
lapack_complex_double *dr, lapack_int *ipvtng, lapack_int *iwork, double *sparse);
```

For gfortran (libmkl_gf_*) interface libraries:

```
lapack_complex_float clatm2 (lapack_int *m, lapack_int *n, lapack_int *i, lapack_int
*j, lapack_int *kl, lapack_int *ku, lapack_int *idist, lapack_int *iseed,
lapack_complex_float *d, lapack_int *igrade, lapack_complex_float *dl,
lapack_complex_float *dr, lapack_int *ipvtng, lapack_int *iwork, float *sparse);

lapack_complex_double zlatm2 (lapack_int *m, lapack_int *n, lapack_int *i, lapack_int
*j, lapack_int *kl, lapack_int *ku, lapack_int *idist, lapack_int *iseed,
lapack_complex_double *d, lapack_int *igrade, lapack_complex_double *dl,
lapack_complex_double *dr, lapack_int *ipvtng, lapack_int *iwork, double *sparse);
```

To understand the difference between the non-gfortran and gfortran interfaces and when to use each of them, see Dynamic Libraries in the lib/intel64 Directory in the *Intel MKL User's Guide*.

Include Files

- `mk1.h`

Description

The `?latm2` routine returns entry (i, j) of a random matrix of dimension (m, n) . It is called by the `?latmr` routine in order to build random test matrices. No error checking on parameters is done, because this routine is called in a tight loop by `?latmr` which has already checked the parameters.

Use of `?latm2` differs from `?latm3` in the order in which the random number generator is called to fill in random matrix entries. With `?latm2`, the generator is called to fill in the pivoted matrix columnwise. With `?latm3`, the generator is called to fill in the matrix columnwise, after which it is pivoted. Thus, `?latm3` can be used to construct random matrices which differ only in their order of rows and/or columns. `?latm2` is used to construct band matrices while avoiding calling the random number generator for entries outside the band (and therefore generating random numbers).

The matrix whose (i, j) entry is returned is constructed as follows (this routine only computes one entry):

- If i is outside $(1..m)$ or j is outside $(1..n)$, returns zero (this is convenient for generating matrices in band format).
- Generate a matrix A with random entries of distribution *idist*.
- Set the diagonal to D .
- Grade the matrix, if desired, from the left (by *dl*) and/or from the right (by *dr* or *dl*) as specified by *igrade*.
- Permute, if desired, the rows and/or columns as specified by *ipvtng* and *iwork*.
- Band the matrix to have lower bandwidth *kl* and upper bandwidth *ku*.
- Set random entries to zero as specified by *sparse*.

Input Parameters

<i>m</i>	Number of rows of the matrix.
<i>n</i>	Number of columns of the matrix.
<i>i</i>	Row of the entry to be returned.
<i>j</i>	Column of the entry to be returned.
<i>kl</i>	Lower bandwidth.
<i>ku</i>	Upper bandwidth.
<i>idist</i>	On entry, <i>idist</i> specifies the type of distribution to be used to generate a random matrix . for <code>slatm2</code> and <code>dlatm2</code> : = 1: uniform (0,1) = 2: uniform (-1,1) = 3: normal (0,1) for <code>clatm2</code> and <code>zlatm2</code> : = 1: real and imaginary parts each uniform (0,1) = 2: real and imaginary parts each uniform (-1,1) = 3: real and imaginary parts each normal (0,1)

	= 4: complex number uniform in disk (0, 1)
<i>iseed</i>	Array, size 4. Seed for the random number generator.
<i>d</i>	Array, size $(\min(i, j))$. Diagonal entries of matrix.
<i>igrade</i>	Specifies grading of matrix as follows: = 0: no grading = 1: matrix premultiplied by $\text{diag}(dl)$ = 2: matrix postmultiplied by $\text{diag}(dr)$ = 3: matrix premultiplied by $\text{diag}(dl)$ and postmultiplied by $\text{diag}(dr)$ = 4: matrix premultiplied by $\text{diag}(dl)$ and postmultiplied by $\text{inv}(\text{diag}(dl))$ For <i>slatm2</i> and <i>slatm2</i> : = 5: matrix premultiplied by $\text{diag}(dl)$ and postmultiplied by $\text{diag}(dl)$ For <i>clatm2</i> and <i>zlatm2</i> : = 5: matrix premultiplied by $\text{diag}(dl)$ and postmultiplied by $\text{diag}(\text{conjg}(dl))$ = 6: matrix premultiplied by $\text{diag}(dl)$ and postmultiplied by $\text{diag}(dl)$
<i>dl</i>	Array, size (<i>i</i> or <i>j</i>), as appropriate. Left scale factors for grading matrix.
<i>dr</i>	Array, size (<i>i</i> or <i>j</i>), as appropriate. Right scale factors for grading matrix.
<i>ipvtng</i>	On entry specifies pivoting permutations as follows: = 0: none = 1: row pivoting = 2: column pivoting = 3: full pivoting, i.e., on both sides
<i>iwork</i>	Array, size (<i>i</i> or <i>j</i>), as appropriate. This array specifies the permutation used. The row (or column) in position <i>k</i> was originally in position <i>iwork</i> [<i>k</i> - 1]. This differs from <i>iwork</i> for <i>?latm3</i> .
<i>sparse</i>	Specifies the sparsity of the matrix. If sparse matrix is to be generated, <i>sparse</i> should lie between 0 and 1. A uniform (0, 1) random number <i>x</i> is generated and compared to <i>sparse</i> . If <i>x</i> is larger the matrix entry is unchanged and if <i>x</i> is smaller the entry is set to zero. Thus on the average a fraction <i>sparse</i> of the entries will be set to zero.

Output Parameters

<i>iseed</i>	On exit, the seed is updated.

Return Values

The function returns an entry of a random matrix (for complex variations libmkl_gf_* interface layer/ libraries return the result as the parameter *res*).

?latm3

Returns set entry of a random matrix.

Syntax

```
float slatm3 (lapack_int *m, lapack_int *n, lapack_int *i, lapack_int *j, lapack_int
*isub, lapack_int *jsub, lapack_int *kl, lapack_int *ku, lapack_int *idist, lapack_int
*iseed, float *d, lapack_int *igrade, float *dl, float *dr, lapack_int *ipvtng,
lapack_int *iwork, float *sparse);

double dlatm3 (lapack_int *m, lapack_int *n, lapack_int *i, lapack_int *j, lapack_int
*isub, lapack_int *jsub, lapack_int *kl, lapack_int *ku, lapack_int *idist, lapack_int
*iseed, double *d, lapack_int *igrade, double *dl, double *dr, lapack_int *ipvtng,
lapack_int *iwork, double *sparse);
```

The data types for complex variations depend on whether or not the application links with Gnu Fortran (gfortran) libraries.

For non-gfortran (libmkl_intel_*) interface libraries:

```
void clatm3 (lapack_complex_float *res, lapack_int *m, lapack_int *n, lapack_int *i,
lapack_int *j, lapack_int *isub, lapack_int *jsub, lapack_int *kl, lapack_int *ku,
lapack_int *idist, lapack_int *iseed, lapack_complex_float *d, lapack_int *igrade,
lapack_complex_float *dl, lapack_complex_float *dr, lapack_int *ipvtng, lapack_int
*iwork, float *sparse);

void zlatm3 (lapack_complex_double *res, lapack_int *m, lapack_int *n, lapack_int *i,
lapack_int *j, lapack_int *isub, lapack_int *jsub, lapack_int *kl, lapack_int *ku,
lapack_int *idist, lapack_int *iseed, lapack_complex_double *d, lapack_int *igrade,
lapack_complex_double *dl, lapack_complex_double *dr, lapack_int *ipvtng, lapack_int
*iwork, double *sparse);
```

For gfortran (libmkl_gf_*) interface libraries:

```
lapack_complex_float clatm3 (lapack_int *m, lapack_int *n, lapack_int *i, lapack_int
*j, lapack_int *isub, lapack_int *jsub, lapack_int *kl, lapack_int *ku, lapack_int
*idist, lapack_int *iseed, lapack_complex_float *d, lapack_int *igrade,
lapack_complex_float *dl, lapack_complex_float *dr, lapack_int *ipvtng, lapack_int
*iwork, float *sparse);

lapack_complex_double zlatm3 (lapack_int *m, lapack_int *n, lapack_int *i, lapack_int
*j, lapack_int *isub, lapack_int *jsub, lapack_int *kl, lapack_int *ku, lapack_int
*idist, lapack_int *iseed, lapack_complex_double *d, lapack_int *igrade,
lapack_complex_double *dl, lapack_complex_double *dr, lapack_int *ipvtng, lapack_int
*iwork, double *sparse);
```

To understand the difference between the non-gfortran and gfortran interfaces and when to use each of them, see Dynamic Libraries in the lib/intel64 Directory in the *Intel MKL User's Guide*.

Include Files

- mkl.h

Description

The `?latm3` routine returns the $(isub, jsub)$ entry of a random matrix of dimension (m, n) described by the other parameters. $(isub, jsub)$ is the final position of the (i, j) entry after pivoting according to *ipvtng* and *iwork*. `?latm3` is called by the `?latmr` routine in order to build random test matrices. No error checking on parameters is done, because this routine is called in a tight loop by `?latmr` which has already checked the parameters.

Use of `?latm3` differs from `?latm2` in the order in which the random number generator is called to fill in random matrix entries. With `?latm2`, the generator is called to fill in the pivoted matrix columnwise. With `?latm3`, the generator is called to fill in the matrix columnwise, after which it is pivoted. Thus, `?latm3` can be used to construct random matrices which differ only in their order of rows and/or columns. `?latm2` is used to construct band matrices while avoiding calling the random number generator for entries outside the band (and therefore generating random numbers in different orders for different pivot orders).

The matrix whose $(isub, jsub)$ entry is returned is constructed as follows (this routine only computes one entry):

- If *isub* is outside $(1..m)$ or *jsub* is outside $(1..n)$, returns zero (this is convenient for generating matrices in band format).
- Generate a matrix *A* with random entries of distribution *idist*.
- Set the diagonal to *D*.
- Grade the matrix, if desired, from the left (by *dl*) and/or from the right (by *dr* or *dl*) as specified by *igrade*.
- Permute, if desired, the rows and/or columns as specified by *ipvtng* and *iwork*.
- Band the matrix to have lower bandwidth *kl* and upper bandwidth *ku*.
- Set random entries to zero as specified by *sparse*.

Input Parameters

<i>m</i>	Number of rows of matrix.
<i>n</i>	Number of columns of matrix.
<i>i</i>	Row of unpivoted entry to be returned.
<i>j</i>	Column of unpivoted entry to be returned.
<i>isub</i>	Row of pivoted entry to be returned.
<i>jsub</i>	Column of pivoted entry to be returned.
<i>kl</i>	Lower bandwidth.
<i>ku</i>	Upper bandwidth.
<i>idist</i>	On entry, <i>idist</i> specifies the type of distribution to be used to generate a random matrix. for <code>slatm2</code> and <code>dlatm2</code> : = 1: uniform (0,1) = 2: uniform (-1,1) = 3: normal (0,1) for <code>clatm2</code> and <code>zlatm2</code> : = 1: real and imaginary parts each uniform (0,1)

- = 2: real and imaginary parts each uniform (-1,1)
- = 3: real and imaginary parts each normal (0,1)
- = 4: complex number uniform in disk(0, 1)

iseed

Array, size 4.

Seed for random number generator.

d

Array, size $(\min(i, j))$. Diagonal entries of matrix.

igrade

Specifies grading of matrix as follows:

= 0: no grading

= 1: matrix premultiplied by $\text{diag}(dl)$

= 2: matrix postmultiplied by $\text{diag}(dr)$

= 3: matrix premultiplied by $\text{diag}(dl)$ and postmultiplied by $\text{diag}(dr)$

= 4: matrix premultiplied by $\text{diag}(dl)$ and postmultiplied by $\text{inv}(\text{diag}(dl))$

For `slatm2` and `slatm2`:

= 5: matrix premultiplied by $\text{diag}(dl)$ and postmultiplied by $\text{diag}(dl)$

For `clatm2` and `zlatm2`:

= 5: matrix premultiplied by $\text{diag}(dl)$ and postmultiplied by $\text{diag}(\text{conjg}(dl))$

= 6: matrix premultiplied by $\text{diag}(dl)$ and postmultiplied by $\text{diag}(dl)$

dl

Array, size (*i* or *j*, as appropriate).

Left scale factors for grading matrix.

dr

Array, size (*i* or *j*, as appropriate).

Right scale factors for grading matrix.

ipvtng

On entry specifies pivoting permutations as follows:

If *ipvtng* = 0: none.

If *ipvtng* = 1: row pivoting.

If *ipvtng* = 2: column pivoting.

If *ipvtng* = 3: full pivoting, i.e., on both sides.

sparse

On entry, specifies the sparsity of the matrix if sparse matrix is to be generated. *sparse* should lie between 0 and 1. A $\text{uniform}(0, 1)$ random number *x* is generated and compared to *sparse*; if *x* is larger the matrix entry is unchanged and if *x* is smaller the entry is set to zero. Thus on the average a fraction *sparse* of the entries will be set to zero.

iwork

Array, size (*i* or *j*, as appropriate). This array specifies the permutation used. The row (or column) originally in position *k* is in position *iwork*[*k* - 1] after pivoting. This differs from *iwork* for `?latm2`.

Output Parameters

<i>isub</i>	On exit, row of pivoted entry is updated.
<i>jsub</i>	On exit, column of pivoted entry is updated.
<i>iseed</i>	On exit, the seed is updated.

Return Values

The function returns an entry of a random matrix (for complex variations `libmkl_gf_*` interface layer/ libraries return the result as the parameter *res*).

?latm5

Generates matrices involved in the Generalized Sylvester equation.

Syntax

```
void slatm5 (*prtype, lapack_int *m, lapack_int *n, float *a, lapack_int *lda, float
*b, lapack_int *ldb, float *c, lapack_int *ldc, float *d, lapack_int *ldd, float *e,
lapack_int *lde, float *f, lapack_int *ldf, float *r, lapack_int *ldr, float *l,
lapack_int *ldl, float *alpha, lapack_int *qblcka, lapack_int *qblckb);

void dlatm5 (*prtype, lapack_int *m, lapack_int *n, double *a, lapack_int *lda, double
*b, lapack_int *ldb, double *c, lapack_int *ldc, double *d, lapack_int *ldd, double
*e, lapack_int *lde, double *f, lapack_int *ldf, double *r, lapack_int *ldr, double
*l, lapack_int *ldl, double *alpha, lapack_int *qblcka, lapack_int *qblckb);

void clatm5 (*prtype, lapack_int *m, lapack_int *n, lapack_complex_float *a, lapack_int
*lda, lapack_complex_float *b, lapack_int *ldb, lapack_complex_float *c, lapack_int
*ldc, lapack_complex_float *d, lapack_int *ldd, lapack_complex_float *e, lapack_int
*lde, lapack_complex_float *f, lapack_int *ldf, lapack_complex_float *r, lapack_int
*ldr, lapack_complex_float *l, lapack_int *ldl, float *alpha, lapack_int *qblcka,
lapack_int *qblckb);

void zlatm5 (*prtype, lapack_int *m, lapack_int *n, lapack_complex_double *a,
lapack_int *lda, lapack_complex_double *b, lapack_int *ldb, lapack_complex_double *c,
lapack_int *ldc, lapack_complex_double *d, lapack_int *ldd, lapack_complex_double *e,
lapack_int *lde, lapack_complex_double *f, lapack_int *ldf, lapack_complex_double *r,
lapack_int *ldr, lapack_complex_double *l, lapack_int *ldl, float *alpha, lapack_int
*qblcka, lapack_int *qblckb);
```

Include Files

- `mkl.h`

Description

The `?latm5` routine generates matrices involved in the Generalized Sylvester equation:

$$A * R - L * B = C$$

$$D * R - L * E = F$$

They also satisfy the diagonalization condition:

$$\begin{bmatrix} I & -L \\ & I \end{bmatrix} \begin{bmatrix} A & -C \\ & B \end{bmatrix} \begin{bmatrix} I & R \\ & I \end{bmatrix} = \begin{bmatrix} A & \\ & B \end{bmatrix}$$

$$\begin{bmatrix} I & -L \\ & I \end{bmatrix} \begin{bmatrix} D & -F \\ & E \end{bmatrix} \begin{bmatrix} I & R \\ & I \end{bmatrix} = \begin{bmatrix} D & \\ & E \end{bmatrix}$$

Input Parameters

prtype

Specifies the type of matrices to generate.

- If *prtype* = 1, *A* and *B* are Jordan blocks, *D* and *E* are identity matrices.

A:

If (*i* == *j*) then $A_{i,j} = 1.0$.

If (*j* == *i* + 1) then $A_{i,j} = -1.0$.

Otherwise $A_{i,j} = 0.0$, *i*, *j* = 1...*m*

B:

If (*i* == *j*) then $B_{i,j} = 1.0 - \alpha$.

If (*j* == *i* + 1) then $B_{i,j} = 1.0$.

Otherwise $B_{i,j} = 0.0$, *i*, *j* = 1...*n*.

D:

If (*i* == *j*) then $D_{i,j} = 1.0$.

Otherwise $D_{i,j} = 0.0$, *i*, *j* = 1...*m*.

E:

If (*i* == *j*) then $E_{i,j} = 1.0$

Otherwise $E_{i,j} = 0.0$, *i*, *j* = 1...*n*.

L = *R* are chosen from [-10...10], which specifies the right hand sides (*C*, *F*).

- If *prtype* = 2 or 3: Triangular and/or quasi- triangular.

A:

If (*i* ≤ *j*) then $A_{i,j} = [-1...1]$.

Otherwise $A_{i,j} = 0.0$, *i*, *j* = 1...*M*.

If (*prtype* = 3) then $A_{k+1,k+1} = A_{k,k}$;

$A_{k+1,k} = [-1...1]$;

$\text{sign}(A_{k,k+1}) = -(\text{sign}(A_{k+1,k}))$.

k = 1, *m* - 1, *qblocka*

B :

If (*i* ≤ *j*) then $B_{i,j} = [-1...1]$.

Otherwise $B_{i,j} = 0.0$, *i*, *j* = 1...*n*.

If (*prtype* = 3) then $B_{k+1,k+1} = B_{k,k}$

$B_{k+1,k} = [-1...1]$

$\text{sign}(B_{k, k+1}) = -(\text{sign}(B_{k+1, k}))$

$k = 1, n-1, qblckb.$

D:

If $(i \leq j)$ then $D_{i,j} = [-1 \dots 1].$

Otherwise $D_{i,j} = 0.0, i, j = 1 \dots m.$

E:

If $(i \leq j)$ then $E_{i,j} = [-1 \dots 1].$

Otherwise $E_{i,j} = 0.0, i, j = 1 \dots N.$

L, R are chosen from $[-10 \dots 10]$, which specifies the right hand sides (*C, F*).

- If *prtype* = 4 Full

$A_{i,j} = [-10 \dots 10]$

$D_{i,j} = [-1 \dots 1] \quad i, j = 1 \dots m$

$B_{i,j} = [-10 \dots 10]$

$E_{i,j} = [-1 \dots 1] \quad i, j = 1 \dots n$

$R_{i,j} = [-10 \dots 10]$

$L_{i,j} = [-1 \dots 1] \quad i = 1 \dots m, j = 1 \dots n$

L and *R* specifies the right hand sides (*C, F*).

- If *prtype* = 5 special case common and/or close eigs.

<i>m</i>	Specifies the order of <i>A</i> and <i>D</i> and the number of rows in <i>C, F, R</i> and <i>L</i> .
<i>n</i>	Specifies the order of <i>B</i> and <i>E</i> and the number of columns in <i>C, F, R</i> and <i>L</i> .
<i>lda</i>	The leading dimension of <i>a</i> .
<i>ldb</i>	The leading dimension of <i>b</i> .
<i>ldc</i>	The leading dimension of <i>c</i> .
<i>ldd</i>	The leading dimension of <i>d</i> .
<i>lde</i>	The leading dimension of <i>e</i> .
<i>ldf</i>	The leading dimension of <i>f</i> .
<i>ldr</i>	The leading dimension of <i>r</i> .
<i>ldl</i>	The leading dimension of <i>l</i> .
<i>alpha</i>	Parameter used in generating <i>prtype</i> = 1 and 5 matrices.
<i>qblcka</i>	When <i>prtype</i> = 3, specifies the distance between 2-by-2 blocks on the diagonal in <i>A</i> . Otherwise, <i>qblcka</i> is not referenced. <i>qblcka</i> > 1.
<i>qblckb</i>	When <i>prtype</i> = 3, specifies the distance between 2-by-2 blocks on the diagonal in <i>B</i> . Otherwise, <i>qblckb</i> is not referenced. <i>qblckb</i> > 1.

Output Parameters

<i>a</i>	Array, size <i>lda</i> * <i>m</i> . On exit <i>a</i> contains the <i>m</i> -by- <i>m</i> array <i>A</i> initialized according to <i>prtype</i> .
<i>b</i>	Array, size <i>ldb</i> * <i>n</i> . On exit <i>b</i> contains the <i>n</i> -by- <i>n</i> array <i>B</i> initialized according to <i>prtype</i> .
<i>c</i>	Array, size <i>ldc</i> * <i>n</i> . On exit <i>c</i> contains the <i>m</i> -by- <i>n</i> array <i>C</i> initialized according to <i>prtype</i> .
<i>d</i>	Array, size <i>ldd</i> * <i>m</i> . On exit <i>d</i> contains the <i>m</i> -by- <i>m</i> array <i>D</i> initialized according to <i>prtype</i> .
<i>e</i>	Array, size <i>lde</i> * <i>n</i> . On exit <i>e</i> contains the <i>n</i> -by- <i>n</i> array <i>E</i> initialized according to <i>prtype</i> .
<i>f</i>	Array, size <i>ldf</i> * <i>n</i> . On exit <i>f</i> contains the <i>m</i> -by- <i>n</i> array <i>F</i> initialized according to <i>prtype</i> .
<i>r</i>	Array, size <i>ldr</i> * <i>n</i> . On exit <i>R</i> contains the <i>m</i> -by- <i>n</i> array <i>R</i> initialized according to <i>prtype</i> .
<i>l</i>	Array, size <i>ldl</i> * <i>n</i> . On exit <i>l</i> contains the <i>m</i> -by- <i>n</i> array <i>L</i> initialized according to <i>prtype</i> .

?latm6

Generates test matrices for the generalized eigenvalue problem, their corresponding right and left eigenvector matrices, and also reciprocal condition numbers for all eigenvalues and the reciprocal condition numbers of eigenvectors corresponding to the 1th and 5th eigenvalues.

Syntax

```
void slatm6 (lapack_int *type, lapack_int *n, float *a, lapack_int *lda, float *b,
float *x, lapack_int *ldx, float *y, lapack_int *ldy, float *alpha, float *beta, float
*wx, float *wy, float *s, float *dif);

void dlatm6 (lapack_int *type, lapack_int *n, double *a, lapack_int *lda, double *b,
double *x, lapack_int *ldx, double *y, lapack_int *ldy, double *alpha, double *beta,
double *wx, double *wy, double *s, double *dif);

void clatm6 (lapack_int *type, lapack_int *n, lapack_complex_float *a, lapack_int *lda,
lapack_complex_float *b, lapack_complex_float *x, lapack_int *ldx, lapack_complex_float
*y, lapack_int *ldy, lapack_complex_float *alpha, lapack_complex_float *beta,
lapack_complex_float *wx, lapack_complex_float *wy, float *s, float *dif);

void zlatm6 (lapack_int *type, lapack_int *n, lapack_complex_double *a, lapack_int
*lda, lapack_complex_double *b, lapack_complex_double *x, lapack_int *ldx,
lapack_complex_double *y, lapack_int *ldy, lapack_complex_double *alpha,
lapack_complex_double *beta, lapack_complex_double *wx, lapack_complex_double *wy,
double *s, double *dif);
```

Description

The `?latm6` routine generates test matrices for the generalized eigenvalue problem, their corresponding right and left eigenvector matrices, and also reciprocal condition numbers for all eigenvalues and the reciprocal condition numbers of eigenvectors corresponding to the 1th and 5th eigenvalues.

There two kinds of test matrix pairs:

$$(A, B) = \text{inverse}(YH) * (Da, Db) * \text{inverse}(X)$$

Type 1:

$$Da = \begin{bmatrix} 1+a & 0 & 0 & 0 & 0 \\ 0 & 2+a & 0 & 0 & 0 \\ 0 & 0 & 3+a & 0 & 0 \\ 0 & 0 & 0 & 4+a & 0 \\ 0 & 0 & 0 & 0 & 5+2 \end{bmatrix} \quad Db = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix}$$

Type 2:

$$Da = \begin{bmatrix} 1+i & 0 & 0 & 0 & 0 \\ 0 & 1-i & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & (1+a)+(1+b)i & 0 \\ 0 & 0 & 0 & 0 & (1+a)-(1+b)i \end{bmatrix} \quad Db = \begin{bmatrix} 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix}$$

In both cases the same `inverse(YH)` and `inverse(X)` are used to compute (A, B) , giving the exact eigenvectors to (A, B) as (YH, X) :

$$YH = \begin{bmatrix} 1 & 0 & -y & y & -y \\ 0 & 1 & -y & y & -y \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix} \quad X = \begin{bmatrix} 1 & 0 & -x & -x & x \\ 0 & 1 & x & -x & -x \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix},$$

where a, b, x and y will have all values independently of each other.

Input Parameters

<i>type</i>	Specifies the problem type.
<i>n</i>	Size of the matrices A and B .
<i>lda</i>	The leading dimension of a and of b .
<i>ldx</i>	The leading dimension of x .
<i>ldy</i>	The leading dimension of y .

<i>alpha, beta</i>	Weighting constants for matrix <i>A</i> .
<i>wx</i>	Constant for right eigenvector matrix.
<i>wy</i>	Constant for left eigenvector matrix.

Output Parameters

<i>a</i>	Array, size <i>lda</i> * <i>n</i> . On exit, <i>a</i> contains the <i>n</i> -by- <i>n</i> matrix initialized according to <i>type</i> .
<i>b</i>	Array, size <i>lda</i> * <i>n</i> . On exit, <i>b</i> contains the <i>n</i> -by- <i>n</i> matrix initialized according to <i>type</i> .
<i>x</i>	Array, size <i>ldx</i> * <i>n</i> . On exit, <i>x</i> contains the <i>n</i> -by- <i>n</i> matrix of right eigenvectors.
<i>y</i>	Array, size <i>ldy</i> * <i>n</i> . On exit, <i>y</i> is the <i>n</i> -by- <i>n</i> matrix of left eigenvectors.
<i>s</i>	Array, size (<i>n</i>). <i>s</i> [<i>i</i> - 1] is the reciprocal condition number for eigenvalue <i>i</i> .
<i>dif</i>	Array, size(<i>n</i>). <i>dif</i> [<i>i</i> - 1] is the reciprocal condition number for eigenvector <i>i</i> .

?latme

Generates random non-symmetric square matrices with specified eigenvalues.

Syntax

```

Description

The `?latme` routine generates random non-symmetric square matrices with specified eigenvalues. `?latme` operates by applying the following sequence of operations:

1. Set the diagonal to d , where d may be input or computed according to *mode*, *cond*, *dmax*, and *rsign* as described below.
2. If *upper* = 'T', the upper triangle of a is set to random values out of distribution *dist*.
3. If *sim*='T', a is multiplied on the left by a random matrix X , whose singular values are specified by *ds*, *modes*, and *conds*, and on the right by X inverse.
4. If $kl < n-1$, the lower bandwidth is reduced to kl using Householder transformations. If $ku < n-1$, the upper bandwidth is reduced to ku .
5. If *anorm* is not negative, the matrix is scaled to have maximum-element-norm *anorm*.

NOTE

Since the matrix cannot be reduced beyond Hessenberg form, no packing options are available.

Input Parameters

<i>n</i>	The number of columns (or rows) of A .
<i>dist</i>	On entry, <i>dist</i> specifies the type of distribution to be used to generate the random eigen-/singular values, and on the upper triangle (see <i>upper</i>). If <i>dist</i> = 'U': uniform(0, 1) If <i>dist</i> = 'S': uniform(-1, 1) If <i>dist</i> = 'N': normal(0, 1) If <i>dist</i> = 'D': uniform on the complex disc $z < 1$.
<i>iseed</i>	Array, size 4. On entry <i>iseed</i> specifies the seed of the random number generator. The elements should lie between 0 and 4095 inclusive, and <i>iseed</i>[3] should be odd. The random number generator uses a linear congruential sequence limited to small integers, and so should produce machine independent random numbers.
<i>d</i>	Array, size (<i>n</i>). This array is used to specify the eigenvalues of A. If <i>mode</i> = 0, then d is assumed to contain the eigenvalues. Otherwise they are computed according to <i>mode</i>, <i>cond</i>, <i>dmax</i>, and <i>rsign</i> and placed in d.
<i>mode</i>	On entry <i>mode</i> describes how the eigenvalues are to be specified: <i>mode</i> = 0 means use d (with <i>ei</i> for <i>slatme</i> and <i>dlatme</i>) as input. <i>mode</i> = 1 sets $d[0] = 1$ and $d(2:n)=1.0/cond$. <i>mode</i> = 2 sets $d[0:n - 2] = 1$ and $d[n - 1]=1.0/cond$. <i>mode</i> = 3 sets $d[i - 1] = cond**(-(i-1)/(n-1))$. <i>mode</i> = 4 sets $d[i - 1] = 1 - (i-1)/(n-1)*(1 - 1/cond)$. <i>mode</i> = 5 sets d to random numbers in the range ($1/cond$, 1) such that their logarithms are uniformly distributed.

$mode = 6$ sets d to random numbers from same distribution as the rest of the matrix.

$mode < 0$ has the same meaning as $abs(mode)$, except that the order of the elements of d is reversed.

Thus if $mode$ is between 1 and 4, d has entries ranging from 1 to $1/cond$, if between -1 and -4, d has entries ranging from $1/cond$ to 1.

$cond$

On entry, this is used as described under $mode$ above. If used, it must be ≥ 1 .

$dmax$

If $mode$ is not -6, 0 or 6, the contents of d as computed according to $mode$ and $cond$ are scaled by $dmax / \max(abs(d[i - 1]))$. Note that $dmax$ needs not be positive or real: if $dmax$ is negative or complex (or zero), d will be scaled by a negative or complex number (or zero). If $rsign='F'$ then the largest (absolute) eigenvalue will be equal to $dmax$.

ei

Used by `slatme` and `dlatme` only.

Array, size (n).

If $mode = 0$, and $ei[0]$ is not ' ' (space character), this array specifies which elements of d (on input) are real eigenvalues and which are the real and imaginary parts of a complex conjugate pair of eigenvalues. The elements of ei may then only have the values 'R' and 'I'.

If $ei[j - 1] = 'R'$ and $ei[j] = 'I'$, then the j -th eigenvalue is `cmplx( d[j - 1] , d[j] )`, and the $(j + 1)$ -th is the complex conjugate thereof.

If $ei[j - 1] = ei[j]='R'$, then the j -th eigenvalue is $d[j - 1]$ (i.e., real). $ei[0]$ may not be 'I', nor may two adjacent elements of ei both have the value 'I'.

If $mode$ is not 0, then ei is ignored. If $mode$ is 0 and $ei[0] = ' '$, then the eigenvalues will all be real.

$rsign$

If $mode$ is not 0, 6, or -6, and $rsign = 'T'$, then the elements of d , as computed according to $mode$ and $cond$, are multiplied by a random sign (+1 or -1) for `slatme` and `dlatme` or by a complex number from the unit circle $|z| = 1$ for `clatme` and `zlatme`.

If $rsign = 'F'$, the elements of d are not multiplied. $rsign$ may only have the values 'T' or 'F'.

$upper$

If $upper = 'T'$, then the elements of a above the diagonal will be set to random numbers out of $dist$.

If $upper = 'F'$, they will not. $upper$ may only have the values 'T' or 'F'.

sim

If $sim = 'T'$, then a will be operated on by a "similarity transform", i.e., multiplied on the left by a matrix X and on the right by X inverse. $X = USV$, where U and V are random unitary matrices and S is a (diagonal) matrix of singular values specified by ds , $modes$, and $conds$.

If $sim = 'F'$, then a will not be transformed.

<i>ds</i>	This array is used to specify the singular values of X , in the same way that d specifies the eigenvalues of a . If $mode = 0$, the ds contains the singular values, which may not be zero.
<i>modes</i>	Similar to $mode$, but for specifying the diagonal of S . $modes = -6$ and $+6$ are not allowed (since they would result in randomly ill-conditioned eigenvalues.)
<i>conds</i>	Similar to $cond$, but for specifying the diagonal of S .
<i>kl</i>	This specifies the lower bandwidth of the matrix. $kl = 1$ specifies upper Hessenberg form. If kl is at least $n-1$, then A will have full lower bandwidth.
<i>ku</i>	This specifies the upper bandwidth of the matrix. $ku = 1$ specifies lower Hessenberg form. If ku is at least $n-1$, then a will have full upper bandwidth. If ku and kl are both at least $n-1$, then a will be dense. Only one of ku and kl may be less than $n-1$.
<i>anorm</i>	If $anorm$ is not negative, then a is scaled by a non-negative real number to make the maximum-element-norm of a to be $anorm$.
<i>lda</i>	Number of rows of matrix A .
<i>work</i>	Array, size $(3*n)$. Workspace.

Output Parameters

<i>iseed</i>	On exit, the seed is updated.
<i>d</i>	Modified if $mode$ is nonzero.
<i>ds</i>	Modified if $mode$ is nonzero.
<i>a</i>	Array, size $lda*n$. On exit, a is the desired test matrix.
<i>info</i>	If $info = 0$, execution is successful. If $info = -1$, n is negative . If $info = -2$, $dist$ is an illegal string. If $info = -5$, $mode$ is not in range -6 to 6. If $info = -6$, $cond$ is less than 1.0, and $mode$ is not -6, 0, or 6 . If $info = -9$, $rsign$ is not 'T' or 'F' . If $info = -10$, $upper$ is not 'T' or 'F'. If $info = -11$, sim is not 'T' or 'F'. If $info = -12$, $modes = 0$ and ds has a zero singular value. If $info = -13$, $modes$ is not in the range -5 to 5. If $info = -14$, $modes$ is nonzero and $conds$ is less than 1. .

If *info* = -15, *kl* is less than 1.

If *info* = -16, *ku* is less than 1, or *kl* and *ku* are both less than *n*-1.

If *info* = -19, *lda* is less than *m*.

If *info* = 1, error return from ?latm1 (computing *d*) .

If *info* = 2, cannot scale to *dmax* (max. eigenvalue is 0) .

If *info* = 3, error return from slatm1(for slatme and clatme), dlatm1 (for dlatme and zlatme) .

If *info* = 4, error return from ?large.

If *info* = 5, zero singular value from slatm1(for slatme and clatme), dlatm1(for dlatme and zlatme).

?latmr

Generates random matrices of various types.

Syntax

```
void slatmr (lapack_int *m, lapack_int *n, char *dist, lapack_int *iseed, char *sym,

```

Description

The ?latmr routine operates by applying the following sequence of operations:

1. Generate a matrix *A* with random entries of distribution *dist*:

If *sym* = 'S', the matrix is symmetric,

If *sym* = 'H', the matrix is Hermitian,

If *sym* = 'N', the matrix is nonsymmetric.

2. Set the diagonal to *D*, where *D* may be input or computed according to *mode*, *cond*, *dmax* and *rsign* as described below.
3. Grade the matrix, if desired, from the left or right as specified by *grade*. The inputs *dl*, *model*, *concl*, *dr*, *moder* and *condr* also determine the grading as described below.
4. Permute, if desired, the rows and/or columns as specified by *pivtnq* and *ipivot*.
5. Set random entries to zero, if desired, to get a random sparse matrix as specified by *sparse*.
6. Make *A* a band matrix, if desired, by zeroing out the matrix outside a band of lower bandwidth *kl* and upper bandwidth *ku*.
7. Scale *A*, if desired, to have maximum entry *anorm*.
8. Pack the matrix if desired. See options specified by the *pack* parameter.

NOTE

If two calls to ?latmr differ only in the pack parameter, they generate mathematically equivalent matrices. If two calls to ?latmr both have full bandwidth (*kl* = *m*-1 and *ku* = *n*-1), and differ only in the *pivtnq* and *pack* parameters, then the matrices generated differ only in the order of the rows and columns, and otherwise contain the same data. This consistency cannot be and is not maintained with less than full bandwidth.

Input Parameters

<i>m</i>	Number of rows of <i>A</i> .
<i>n</i>	Number of columns of <i>A</i> .
<i>dist</i>	On entry, <i>dist</i> specifies the type of distribution to be used to generate a random matrix . If <i>dist</i> = 'U', real and imaginary parts are independent uniform(0, 1). If <i>dist</i> = 'S', real and imaginary parts are independent uniform(-1, 1). If <i>dist</i> = 'N', real and imaginary parts are independent normal(0, 1). If <i>dist</i> = 'D', distribution is uniform on interior of unit disk.
<i>iseed</i>	Array, size 4. On entry, <i>iseed</i> specifies the seed of the random number generator. They should lie between 0 and 4095 inclusive, and <i>iseed</i> [3] should be odd. The random number generator uses a linear congruential sequence limited to small integers, and so should produce machine independent random numbers.
<i>sym</i>	If <i>sym</i> = 'S', generated matrix is symmetric. If <i>sym</i> = 'H', generated matrix is Hermitian. If <i>sym</i> = 'N', generated matrix is nonsymmetric.
<i>d</i>	On entry this array specifies the diagonal entries of the diagonal of <i>A</i> . <i>d</i> may either be specified on entry, or set according to <i>mode</i> and <i>cond</i> as described below. If the matrix is Hermitian, the real part of <i>d</i> is taken. May be changed on exit if <i>mode</i> is nonzero.
<i>mode</i>	On entry describes how <i>d</i> is to be used:

mode = 0 means use *d* as input.

mode = 1 sets $d[0]=1$ and $d[1:n-1]=1.0/cond$.

mode = 2 sets $d[0:n-2]=1$ and $d[n-1]=1.0/cond$.

mode = 3 sets $d[i-1]=cond^{*(-(i-1)/(n-1))}$.

mode = 4 sets $d[i-1]=1 - (i-1)/(n-1)*(1 - 1/cond)$.

mode = 5 sets *d* to random numbers in the range $(1/cond, 1)$ such that their logarithms are uniformly distributed.

mode = 6 sets *d* to random numbers from same distribution as the rest of the matrix.

mode < 0 has the same meaning as $abs(mode)$, except that the order of the elements of *d* is reversed.

Thus if *mode* is between 1 and 4, *d* has entries ranging from 1 to $1/cond$, if between -1 and -4, *D* has entries ranging from $1/cond$ to 1.

<i>cond</i>	On entry, used as described under <i>mode</i> above. If used, <i>cond</i> must be ≥ 1 .
<i>dmax</i>	If <i>mode</i> is not -6, 0, or 6, the diagonal is scaled by $dmax / \max(abs(d[i]))$, so that maximum absolute entry of diagonal is $abs(dmax)$. If <i>dmax</i> is complex (or zero), the diagonal is scaled by a complex number (or zero).
<i>rsign</i>	If <i>mode</i> is not -6, 0, or 6, specifies the sign of the diagonal as follows: For <i>slatmr</i> and <i>dlatmr</i>, if <i>rsign</i> = 'T', diagonal entries are multiplied 1 or -1 with a probability of 0.5. For <i>clatmr</i> and <i>zlatmr</i>, if <i>rsign</i> = 'T', diagonal entries are multiplied by a random complex number uniformly distributed with absolute value 1. If <i>rsign</i> = 'F', diagonal entries are unchanged.
<i>grade</i>	Specifies grading of matrix as follows: If <i>grade</i> = 'N', there is no grading If <i>grade</i> = 'L', matrix is premultiplied by $diag(dl)$ (only if matrix is nonsymmetric) If <i>grade</i> = 'R', matrix is postmultiplied by $diag(dr)$ (only if matrix is nonsymmetric) If <i>grade</i> = 'B', matrix is premultiplied by $diag(dl)$ and postmultiplied by $diag(dr)$ (only if matrix is nonsymmetric) If <i>grade</i> = 'H', matrix is premultiplied by $diag(dl)$ and postmultiplied by $diag(conjg(dl))$ (only if matrix is Hermitian or nonsymmetric) If <i>grade</i> = 'S', matrix is premultiplied by $diag(dl)$ and postmultiplied by $diag(dl)$ (only if matrix is symmetric or nonsymmetric) If <i>grade</i> = 'E', matrix is premultiplied by $diag(dl)$ and postmultiplied by $inv(diag(dl))$ (only if matrix is nonsymmetric)

NOTE

if *grade* = 'E', then *m* must equal *n*.

<i>dl</i>	Array, size (<i>m</i>). If <i>model</i> = 0, then on entry this array specifies the diagonal entries of a diagonal matrix used as described under <i>grade</i> above. If <i>model</i> is not zero, then <i>dl</i> is set according to <i>model</i> and <i>condl</i>, analogous to the way <i>D</i> is set according to <i>mode</i> and <i>cond</i> (except there is no <i>dmax</i> parameter for <i>dl</i>). If <i>grade</i> = 'E', then <i>dl</i> cannot have zero entries. Not referenced if <i>grade</i> = 'N' or 'R'. Changed on exit.
<i>model</i>	This specifies how the diagonal array <i>dl</i> is computed, just as <i>mode</i> specifies how <i>D</i> is computed.
<i>condl</i>	When <i>model</i> is not zero, this specifies the condition number of the computed <i>dl</i> .
<i>dr</i>	If <i>moder</i> = 0, then on entry this array specifies the diagonal entries of a diagonal matrix used as described under <i>grade</i> above. If <i>moder</i> is not zero, then <i>dr</i> is set according to <i>moder</i> and <i>condr</i>, analogous to the way <i>d</i> is set according to <i>mode</i> and <i>cond</i> (except there is no <i>dmax</i> parameter for <i>dr</i>). Not referenced if <i>grade</i> = 'N', 'L', 'H' 'S' or 'E'.
<i>moder</i>	This specifies how the diagonal array <i>dr</i> is to be computed, just as <i>mode</i> specifies how <i>d</i> is to be computed.
<i>condr</i>	When <i>moder</i> is not zero, this specifies the condition number of the computed <i>dr</i> .
<i>pivtnng</i>	On entry specifies pivoting permutations as follows: If <i>pivtnng</i> = 'N' or ' ': no pivoting permutation. If <i>pivtnng</i> = 'L': left or row pivoting (matrix must be nonsymmetric). If <i>pivtnng</i> = 'R': right or column pivoting (matrix must be nonsymmetric). If <i>pivtnng</i> = 'B' or 'F': both or full pivoting, i.e., on both sides. In this case, <i>m</i> must equal <i>n</i>. If two calls to ?latmr both have full bandwidth (<i>kl</i> = <i>m</i> - 1 and <i>ku</i> = <i>n</i> - 1), and differ only in the <i>pivtnng</i> and <i>pack</i> parameters, then the matrices generated differs only in the order of the rows and columns, and otherwise contain the same data. This consistency cannot be maintained with less than full bandwidth.
<i>ipivot</i>	Array, size (<i>n</i> or <i>m</i>) This array specifies the permutation used. After the basic matrix is generated, the rows, columns, or both are permuted.

If row pivoting is selected, `?latmr` starts with the last row and interchanges row m and row $ipivot[m - 1]$, then moves to the next-to-last row, interchanging rows $[m - 2]$ and row $ipivot[m - 2]$, and so on. In terms of "2-cycles", the permutation is $(1\ ipivot[0])\ (2\ ipivot[1])\ \dots\ (m\ ipivot[m - 1])$ where the rightmost cycle is applied first. This is the inverse of the effect of pivoting in LINPACK. The idea is that factoring (with pivoting) an identity matrix which has been inverse-pivoted in this way should result in a pivot vector identical to $ipivot$. Not referenced if $pivtno = 'N'$.

sparse

On entry, specifies the sparsity of the matrix if a sparse matrix is to be generated. *sparse* should lie between 0 and 1. To generate a sparse matrix, for each matrix entry a uniform (0, 1) random number x is generated and compared to *sparse*; if x is larger the matrix entry is unchanged and if x is smaller the entry is set to zero. Thus on the average a fraction *sparse* of the entries is set to zero.

kl

On entry, specifies the lower bandwidth of the matrix. For example, $kl = 0$ implies upper triangular, $kl = 1$ implies upper Hessenberg, and kl at least $m-1$ implies the matrix is not banded. Must equal *ku* if matrix is symmetric or Hermitian.

ku

On entry, specifies the upper bandwidth of the matrix. For example, $ku = 0$ implies lower triangular, $ku = 1$ implies lower Hessenberg, and ku at least $n-1$ implies the matrix is not banded. Must equal *kl* if matrix is symmetric or Hermitian.

anorm

On entry, specifies maximum entry of output matrix (output matrix is multiplied by a constant so that its largest absolute entry equal *anorm*) if *anorm* is nonnegative. If *anorm* is negative no scaling is done.

pack

On entry, specifies packing of matrix as follows:

If *pack* = 'N': no packing

If *pack* = 'U': zero out all subdiagonal entries (if symmetric or Hermitian)

If *pack* = 'L': zero out all superdiagonal entries (if symmetric or Hermitian)

If *pack* = 'C': store the upper triangle columnwise (only if matrix symmetric or Hermitian or square upper triangular)

If *pack* = 'R': store the lower triangle columnwise (only if matrix symmetric or Hermitian or square lower triangular) (same as upper half rowwise if symmetric) (same as conjugate upper half rowwise if Hermitian)

If *pack* = 'B': store the lower triangle in band storage scheme (only if matrix symmetric or Hermitian)

If *pack* = 'Q': store the upper triangle in band storage scheme (only if matrix symmetric or Hermitian)

If *pack* = 'Z': store the entire matrix in band storage scheme (pivoting can be provided for by using this option to store A in the trailing rows of the allocated storage)

Using these options, the various LAPACK packed and banded storage schemes can be obtained:

LAPACK storage scheme	Value of <i>pack</i>
GB	'Z'
PB, HB or TB	'B' or 'Q'
PP, HP or TP	'C' or 'R'

If two calls to `?latmr` differ only in the *pack* parameter, they generate mathematically equivalent matrices.

lda

On entry, *lda* specifies the first dimension of *a* as declared in the calling program.

If *pack* = 'N', 'U' or 'L', *lda* must be at least $\max(1, m)$.

If *pack* = 'C' or 'R', *lda* must be at least 1.

If *pack* = 'B', or 'Q', *lda* must be $\min(ku + 1, n)$.

If *pack* = 'Z', *lda* must be at least $k_{uu} + k_{ll} + 1$, where $k_{uu} = \min(ku, n-1)$ and $k_{ll} = \min(kl, n-1)$.

iwork

Array, size (*n* or *m*). Workspace. Not referenced if *pivtnng* = 'N'. Changed on exit.

Output Parameters

iseed

On exit, the seed is changed.

d

May be changed on exit if *mode* is nonzero.

dl

On exit, array is changed.

dr

On exit, array is changed.

a

On exit, *a* is the desired test matrix. Only those entries of *a* which are significant on output is referenced (even if *a* is in packed or band storage format). The unoccupied corners of *a* in band format are zeroed out.

info

If *info* = 0, the execution is successful.

If *info* = -1, *m* is negative or unequal to *n* and *sym* = 'S' or 'H'.

If *info* = -2, *n* is negative.

If *info* = -3, *dist* is an illegal string.

If *info* = -5, *sym* is an illegal string..

If *info* = -7, *mode* is not in range -6 to 6.

If *info* = -8, *cond* is less than 1.0, and *mode* is neither -6, 0 nor 6.

If *info* = -10, *mode* is neither -6, 0 nor 6 and *rsign* is an illegal string.

If *info* = -11, *grade* is an illegal string, or *grade* = 'E' and *m* is not equal to *n*, or *grade* = 'L', 'R', 'B', 'S' or 'E' and *sym* = 'H', or *grade* = 'L', 'R', 'B', 'H' or 'E' and *sym* = 'S'

If *info* = -12, *grade* = 'E' and *dl* contains zero.

If *info* = -13, *model* is not in range -6 to 6 and *grade* = 'L', 'B', 'H', 'S' or 'E' .

If *info* = -14, *condl* is less than 1.0, *grade* = 'L', 'B', 'H', 'S' or 'E', and *model* is neither -6, 0 nor 6.

If *info* = -16, *moder* is not in range -6 to 6 and *grade* = 'R' or 'B' .

If *info* = -17, *condr* is less than 1.0, *grade* = 'R' or 'B', and *moder* is neither -6, 0 nor 6 .

If *info* = -18, *pivtnng* is an illegal string, or *pivtnng* = 'B' or 'F' and *m* is not equal to *n*, or *pivtnng* = 'L' or 'R' and *sym* = 'S' or 'H'.

If *info* = -19, *ipivot* contains out of range number and *pivtnng* is not equal to 'N' .

If *info* = -20, *kl* is negative.

If *info* = -21, *ku* is negative, or *sym* = 'S' or 'H' and *ku* not equal to *kl* .

If *info* = -22, *sparse* is not in range 0 to 1.

If *info* = -24, *pack* is an illegal string, or *pack* = 'U', 'L', 'B' or 'Q' and *sym* = 'N', or *pack* = 'C' and *sym* = 'N' and either *kl* is not equal to 0 or *n* is not equal to *m*, or *pack* = 'R' and *sym* = 'N', and either *ku* is not equal to 0 or *n* is not equal to *m* .

If *info* = -26, *lda* is too small .

If *info* = 1, error return from ?latm1 (computing *D*) .

If *info* = 2, cannot scale to *dmax* (max. entry is 0) .

If *info* = 3, error return from ?latm1(computing *dl*) .

If *info* = 4, error return from ?latm1(computing *dr*) .

If *info* = 5, *anorm* is positive, but matrix constructed prior to attempting to scale it to have norm *anorm*, is zero .

?lauum

Computes the product $U*U^T(U*U^H)$ or $L^T*L (L^H*L)$,
where *U* and *L* are upper or lower triangular matrices
(blocked algorithm).

Syntax

```
lapack_int LAPACKE_slauum (int matrix_layout , char uplo , lapack_int n , float * a ,
lapack_int lda );

lapack_int LAPACKE_dlauum (int matrix_layout , char uplo , lapack_int n , double * a ,
lapack_int lda );

lapack_int LAPACKE_clauum (int matrix_layout , char uplo , lapack_int n ,
lapack_complex_float * a , lapack_int lda );

lapack_int LAPACKE_zlauum (int matrix_layout , char uplo , lapack_int n ,
lapack_complex_double * a , lapack_int lda );
```

Include Files

- `mkl.h`

Description

The routine `?lauum` computes the product U^*U^T or L^T*L for real flavors, and U^*U^H or L^H*L for complex flavors. Here the triangular factor U or L is stored in the upper or lower triangular part of the array a .

If `uplo = 'U' or 'u'`, then the upper triangle of the result is stored, overwriting the factor U in A .

If `uplo = 'L' or 'l'`, then the lower triangle of the result is stored, overwriting the factor L in A .

This is the blocked form of the algorithm, calling [BLAS Level 3 Routines](#).

Input Parameters

<code>uplo</code>	Specifies whether the triangular factor stored in the array a is upper or lower triangular: = 'U': Upper triangular = 'L': Lower triangular
<code>n</code>	The order of the triangular factor U or L . $n \geq 0$.
<code>a</code>	Array of size $\max(1, lda * n)$. On entry, the triangular factor U or L .
<code>lda</code>	The leading dimension of the array a . $lda \geq \max(1, n)$.

Output Parameters

<code>a</code>	On exit, if <code>uplo = 'U'</code> , then the upper triangle of a is overwritten with the upper triangle of the product $U^*U^T (U^*U^H)$; if <code>uplo = 'L'</code> , then the lower triangle of a is overwritten with the lower triangle of the product $L^T*L (L^H*L)$.

Return Values

This function returns a value `info`.

If `info = 0`, the execution is successful.

If `info = -k`, the k -th parameter had an illegal value.

If `info = -1011`, memory allocation error occurred.

?syswapr

Applies an elementary permutation on the rows and columns of a symmetric matrix.

Syntax

```
lapack_int LAPACKE_ssyswapr (int matrix_layout , char uplo , lapack_int n , float * a ,
lapack_int i1 , lapack_int i2 );

lapack_int LAPACKE_dsyswapr (int matrix_layout , char uplo , lapack_int n , double *
a , lapack_int i1 , lapack_int i2 );
```

```
lapack_int LAPACKE_csyswapr (int matrix_layout , char uplo , lapack_int n ,
lapack_complex_float * a , lapack_int i1 , lapack_int i2 );

lapack_int LAPACKE_zsyswapr (int matrix_layout , char uplo , lapack_int n ,
lapack_complex_double * a , lapack_int i1 , lapack_int i2 );
```

Include Files

- mkl.h

Description

The routine applies an elementary permutation on the rows and columns of a symmetric matrix.

Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>uplo</i>	Must be 'U' or 'L'. Indicates how the input matrix <i>A</i> has been factored: If <i>uplo</i> = 'U', the array <i>a</i> stores the upper triangular factor <i>U</i> of the factorization $A = U * D * U^T$. If <i>uplo</i> = 'L', the array <i>a</i> stores the lower triangular factor <i>L</i> of the factorization $A = L * D * L^T$.
<i>n</i>	The order of matrix <i>A</i> ; $n \geq 0$.
<i>nrhs</i>	The number of right-hand sides; $nrhs \geq 0$.
<i>a</i>	Array of size at least $\max(1, lda * n)$. The array <i>a</i> contains the block diagonal matrix <i>D</i> and the multipliers used to obtain the factor <i>U</i> or <i>L</i> as computed by ?sytrf.
<i>i1</i>	Index of the first row to swap.
<i>i2</i>	Index of the second row to swap.

Output Parameters

<i>a</i>	If <i>info</i> = 0, the symmetric inverse of the original matrix. If <i>info</i> = 'U', the upper triangular part of the inverse is formed and the part of <i>A</i> below the diagonal is not referenced. If <i>info</i> = 'L', the lower triangular part of the inverse is formed and the part of <i>A</i> above the diagonal is not referenced.

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = -1011, memory allocation error occurred.

See Also[?sytrf](#)**?heswapr**

Applies an elementary permutation on the rows and columns of a Hermitian matrix.

Syntax

```
lapack_int LAPACKE_cheswapr (int matrix_layout, char uplo, lapack_int n,
lapack_complex_float* a, lapack_int i1, lapack_int i2);
```

```

?sfrk

Performs a symmetric rank-k operation for matrix in RFP format.

Syntax

```
lapack_int LAPACKE_ssfrk (int matrix_layout , char transr , char uplo , char trans ,
lapack_int n , lapack_int k , float alpha , const float * a , lapack_int lda , float
beta , float * c );
```

```
lapack_int LAPACKE_dsfrk (int matrix_layout , char transr , char uplo , char trans ,
lapack_int n , lapack_int k , double alpha , const double * a , lapack_int lda ,
double beta , double * c );
```

Include Files

- mkl.h

Description

The ?sfrk routines perform a matrix-matrix operation using symmetric matrices. The operation is defined as

$$C := \alpha A A^T + \beta C,$$

or

$$C := \alpha A^T A + \beta C,$$

where:

alpha and *beta* are scalars,

C is an *n*-by-*n* symmetric matrix in [rectangular full packed \(RFP\) format](#),

A is an *n*-by-*k* matrix in the first case and a *k*-by-*n* matrix in the second case.

Input Parameters

matrix_layout Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).

transr if *transr* = 'N' or 'n', the normal form of RFP C is stored;
if *transr*= 'T' or 't', the transpose form of RFP C is stored.

<i>uplo</i>	Specifies whether the upper or lower triangular part of the array <i>c</i> is used. If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the array <i>c</i> is used. If <i>uplo</i> = 'L' or 'l', then the low triangular part of the array <i>c</i> is used.									
<i>trans</i>	Specifies the operation: if <i>trans</i> = 'N' or 'n', then $C := \alpha A A^T + \beta C$; if <i>trans</i> = 'T' or 't', then $C := \alpha A^T A + \beta C$;									
<i>n</i>	Specifies the order of the matrix <i>C</i> . The value of <i>n</i> must be at least zero.									
<i>k</i>	On entry with <i>trans</i> = 'N' or 'n', <i>k</i> specifies the number of columns of the matrix <i>A</i> , and on entry with <i>trans</i> = 'T' or 't', <i>k</i> specifies the number of rows of the matrix <i>A</i> . The value of <i>k</i> must be at least zero.									
<i>alpha</i>	Specifies the scalar <i>alpha</i> .									
<i>a</i>	Array, size $\max(1, lda * ka)$, where <i>ka</i> is in the following table: <table><tr><td></td><td>Col_major</td><td>Row_major</td></tr><tr><td><i>trans</i> = 'N'</td><td><i>k</i></td><td><i>n</i></td></tr><tr><td><i>trans</i> = 'T'</td><td><i>n</i></td><td><i>k</i></td></tr></table> Before entry with <i>trans</i> = 'N' or 'n', the leading <i>n</i> -by- <i>k</i> part of the array <i>a</i> must contain the matrix <i>A</i> , otherwise the leading <i>k</i> -by- <i>n</i> part of the array <i>a</i> must contain the matrix <i>A</i> .		Col_major	Row_major	<i>trans</i> = 'N'	<i>k</i>	<i>n</i>	<i>trans</i> = 'T'	<i>n</i>	<i>k</i>
	Col_major	Row_major								
<i>trans</i> = 'N'	<i>k</i>	<i>n</i>								
<i>trans</i> = 'T'	<i>n</i>	<i>k</i>								
<i>lda</i>	Specifies the leading dimension of <i>a</i> as declared in the calling (sub)program. <i>lda</i> is defined by the following table: <table><tr><td></td><td>Col_major</td><td>Row_major</td></tr><tr><td><i>trans</i> = 'N'</td><td>$\max(1, n)$</td><td>$\max(1, k)$</td></tr><tr><td><i>trans</i> = 'T'</td><td>$\max(1, k)$</td><td>$\max(1, n)$</td></tr></table>		Col_major	Row_major	<i>trans</i> = 'N'	$\max(1, n)$	$\max(1, k)$	<i>trans</i> = 'T'	$\max(1, k)$	$\max(1, n)$
	Col_major	Row_major								
<i>trans</i> = 'N'	$\max(1, n)$	$\max(1, k)$								
<i>trans</i> = 'T'	$\max(1, k)$	$\max(1, n)$								
<i>beta</i>	Specifies the scalar <i>beta</i> .									
<i>c</i>	Array, size $(n * (n + 1) / 2)$. Before entry contains the symmetric matrix <i>C</i> in RFP format .									

Output Parameters

<i>c</i>	If <i>trans</i> = 'N' or 'n', then <i>c</i> contains $C := \alpha A A^T + \beta C$; if <i>trans</i> = 'T' or 't', then <i>c</i> contains $C := \alpha A^T A + \beta C$;

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* < 0, the *i*-th parameter had an illegal value.

If `info = -1011`, memory allocation error occurred.

?hfrk

Performs a Hermitian rank- k operation for matrix in RFP format.

Syntax

```
lapack_int LAPACKE_chfrk( int matrix_layout, char transr, char uplo, char trans,
lapack_int n, lapack_int k, float alpha, const lapack_complex_float* a, lapack_int
lda, float beta, lapack_complex_float* c );

lapack_int LAPACKE_zhfrk( int matrix_layout, char transr, char uplo, char trans,
lapack_int n, lapack_int k, double alpha, const lapack_complex_double* a, lapack_int
lda, double beta, lapack_complex_double* c );
```

Include Files

- `mkl.h`

Description

The `?hfrk` routines perform a matrix-matrix operation using Hermitian matrices. The operation is defined as

$$C := \alpha A A^H + \beta C,$$

or

$$C := \alpha A^H A + \beta C,$$

where:

α and β are real scalars,

C is an n -by- n Hermitian matrix in [RFP format](#),

A is an n -by- k matrix in the first case and a k -by- n matrix in the second case.

Input Parameters

<code>matrix_layout</code>	Specifies whether matrix storage layout is row major (<code>LAPACK_ROW_MAJOR</code>) or column major (<code>LAPACK_COL_MAJOR</code>).
<code>transr</code>	if <code>transr = 'N'</code> or <code>'n'</code> , the normal form of RFP C is stored; if <code>transr = 'C'</code> or <code>'c'</code> , the conjugate-transpose form of RFP C is stored.
<code>uplo</code>	Specifies whether the upper or lower triangular part of the array c is used. If <code>uplo = 'U'</code> or <code>'u'</code> , then the upper triangular part of the array c is used. If <code>uplo = 'L'</code> or <code>'l'</code> , then the low triangular part of the array c is used.
<code>trans</code>	Specifies the operation: if <code>trans = 'N'</code> or <code>'n'</code> , then $C := \alpha A A^H + \beta C$; if <code>trans = 'C'</code> or <code>'c'</code> , then $C := \alpha A^H A + \beta C$.
<code>n</code>	Specifies the order of the matrix C . The value of n must be at least zero.

k On entry with *trans* = 'N' or 'n', *k* specifies the number of columns of the matrix *a*, and on entry with *trans* = 'T' or 't' or 'C' or 'c', *k* specifies the number of rows of the matrix *a*.
The value of *k* must be at least zero.

alpha Specifies the scalar *alpha*.

a Array, size $\max(1, lda \cdot ka)$, where *ka* is in the following table:

	Col_major	Row_major
<i>trans</i> = 'N'	<i>k</i>	<i>n</i>
<i>trans</i> = 'T'	<i>n</i>	<i>k</i>

Before entry with *trans* = 'N' or 'n', the leading *n*-by-*k* part of the array *a* must contain the matrix *A*, otherwise the leading *k*-by-*n* part of the array *a* must contain the matrix *A*.

lda Specifies the leading dimension of *a* as declared in the calling (sub)program. *lda* is defined by the following table:

	Col_major	Row_major
<i>trans</i> = 'N'	$\max(1, n)$	$\max(1, k)$
<i>trans</i> = 'T'	$\max(1, k)$	$\max(1, n)$

beta Specifies the scalar *beta*.

c Array, size $(n \cdot (n+1) / 2)$. Before entry contains the Hermitian matrix *C* in [RFP format](#).

Output Parameters

c If *trans* = 'N' or 'n', then *c* contains $C := \alpha A A^H + \beta C$;
if *trans* = 'C' or 'c', then *c* contains $C := \alpha A^H A + \beta C$;

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* < 0, the *i*-th parameter had an illegal value.

If *info* = -1011, memory allocation error occurred.

?tfsm

Solves a matrix equation (one operand is a triangular matrix in RFP format).

Syntax

```
lapack_int LAPACKE_stfsm (int matrix_layout , char transr , char side , char uplo ,
char trans , char diag , lapack_int m , lapack_int n , float alpha , const float * a ,
float * b , lapack_int ldb );
```

```
lapack_int LAPACKE_dtfsm (int matrix_layout , char transr , char side , char uplo ,
char trans , char diag , lapack_int m , lapack_int n , double alpha , const double *
a , double * b , lapack_int ldb );
```

```
lapack_int LAPACKE_ctfsm (int matrix_layout , char transr , char side , char uplo ,

Description

The ?tfsm routines solve one of the following matrix equations:

$\text{op}(A) * X = \alpha * B,$

or

$X * \text{op}(A) = \alpha * B,$

where:

α is a scalar,

X and B are m -by- n matrices,

A is a unit, or non-unit, upper or lower triangular matrix in [rectangular full packed \(RFP\) format](#).

$\text{op}(A)$ can be one of the following:

- $\text{op}(A) = A$ or $\text{op}(A) = A^T$ for real flavors
- $\text{op}(A) = A$ or $\text{op}(A) = A^H$ for complex flavors

The matrix B is overwritten by the solution matrix X .

Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>transr</i>	if <i>transr</i> = 'N' or 'n', the normal form of RFP A is stored; if <i>transr</i> = 'T' or 't', the transpose form of RFP A is stored; if <i>transr</i> = 'C' or 'c', the conjugate-transpose form of RFP A is stored.
<i>side</i>	Specifies whether $\text{op}(A)$ appears on the left or right of X in the equation: if <i>side</i> = 'L' or 'l', then $\text{op}(A) * X = \alpha * B$; if <i>side</i> = 'R' or 'r', then $X * \text{op}(A) = \alpha * B$.
<i>uplo</i>	Specifies whether the RFP matrix A is upper or lower triangular: if <i>uplo</i> = 'U' or 'u', then the matrix is upper triangular; if <i>uplo</i> = 'L' or 'l', then the matrix is low triangular.

<i>trans</i>	Specifies the form of $\text{op}(A)$ used in the matrix multiplication: if <i>trans</i> = 'N' or 'n', then $\text{op}(A) = A$; if <i>trans</i> = 'T' or 't', then $\text{op}(A) = A'$; if <i>trans</i> = 'C' or 'c', then $\text{op}(A) = \text{conjg}(A')$.
<i>diag</i>	Specifies whether the RFP matrix <i>A</i> is unit triangular: if <i>diag</i> = 'U' or 'u' then the matrix is unit triangular; if <i>diag</i> = 'N' or 'n', then the matrix is not unit triangular.
<i>m</i>	Specifies the number of rows of <i>B</i> . The value of <i>m</i> must be at least zero.
<i>n</i>	Specifies the number of columns of <i>B</i> . The value of <i>n</i> must be at least zero.
<i>alpha</i>	Specifies the scalar <i>alpha</i>. When <i>alpha</i> is zero, then <i>a</i> is not referenced and <i>b</i> need not be set before entry.
<i>a</i>	Array, size $(n*(n+1)/2)$. Contains the matrix <i>A</i> in RFP format .
<i>b</i>	Array, size $\max(1, \text{ldb}*n)$ for column major and $\max(1, \text{ldb}*m)$ for row major. Before entry, the leading <i>m</i>-by-<i>n</i> part of the array <i>b</i> must contain the right-hand side matrix <i>B</i>.
<i>ldb</i>	Specifies the leading dimension of <i>b</i> as declared in the calling (sub)program. The value of <i>ldb</i> must be at least $\max(1, m)$ for column major and $\max(1, n)$ for row major.

Output Parameters

<i>b</i>	Overwritten by the solution matrix <i>X</i> .

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* < 0, the *i*-th parameter had an illegal value.

If *info* = -1011, memory allocation error occurred.

?tfttp

Copies a triangular matrix from the rectangular full packed format (TF) to the standard packed format (TP).

Syntax

```
lapack_int LAPACKE_stfttp (int matrix_layout , char transr , char uplo , lapack_int n ,
const float * arf , float * ap );
```

```
lapack_int LAPACKE_dtfttp (int matrix_layout , char transr , char uplo , lapack_int n ,
const double * arf , double * ap );
```

```
lapack_int LAPACKE_ctfttp (int matrix_layout , char transr , char uplo , lapack_int n ,
const lapack_complex_float * arf , lapack_complex_float * ap );

lapack_int LAPACKE_ztfttp (int matrix_layout , char transr , char uplo , lapack_int n ,
const lapack_complex_double * arf , lapack_complex_double * ap );
```

Description

The routine copies a triangular matrix A from the Rectangular Full Packed (RFP) format to the standard packed format. For the description of the RFP format, see [Matrix Storage Schemes](#).

Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>transr</i>	= 'N': <i>arf</i> is in the Normal format, = 'T': <i>arf</i> is in the Transpose format (for stfttp and dtfttp), = 'C': <i>arf</i> is in the Conjugate-transpose format (for ctfttp and ztfttp).
<i>uplo</i>	Specifies whether A is upper or lower triangular: = 'U': A is upper triangular, = 'L': A is lower triangular.
<i>n</i>	The order of the matrix A . $n \geq 0$.
<i>arf</i>	Array, size at least $\max(1, n*(n+1)/2)$. On entry, the upper or lower triangular matrix A stored in the RFP format.

Output Parameters

<i>ap</i>	Array, size at least $\max(1, n*(n+1)/2)$. On exit, the upper or lower triangular matrix A , packed columnwise in a linear array.

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* < 0, the *i*-th parameter had an illegal value.

If *info* = -1011, memory allocation error occurred.

?tfttr

Copies a triangular matrix from the rectangular full packed format (TF) to the standard full format (TR) .

Syntax

```
lapack_int LAPACKE_stfttr (int matrix_layout , char transr , char uplo , lapack_int n ,
const float * arf , float * a , lapack_int lda );
```

```
lapack_int LAPACKE_dftttr (int matrix_layout , char transr , char uplo , lapack_int n ,
const double * arf , double * a , lapack_int lda );
```

```
lapack_int LAPACKE_ctfttr (int matrix_layout , char transr , char uplo , lapack_int n ,
const lapack_complex_float * arf , lapack_complex_float * a , lapack_int lda );
```

```
lapack_int LAPACKE_zftttr (int matrix_layout , char transr , char uplo , lapack_int n ,
const lapack_complex_double * arf , lapack_complex_double * a , lapack_int lda );
```

Description

The routine copies a triangular matrix A from the Rectangular Full Packed (RFP) format to the standard full format. For the description of the RFP format, see [Matrix Storage Schemes](#).

Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>transr</i>	= 'N': <i>arf</i> is in the Normal format, = 'T': <i>arf</i> is in the Transpose format (for <i>stfttr</i> and <i>dftttr</i>), = 'C': <i>arf</i> is in the Conjugate-transpose format (for <i>ctfttr</i> and <i>zftttr</i>).
<i>uplo</i>	Specifies whether A is upper or lower triangular: = 'U': A is upper triangular, = 'L': A is lower triangular.
<i>n</i>	The order of the matrices <i>arf</i> and a . $n \geq 0$.
<i>arf</i>	Array, size at least $\max(1, n*(n+1)/2)$. On entry, the upper or lower triangular matrix A stored in the RFP format.
<i>lda</i>	The leading dimension of the array a . $lda \geq \max(1, n)$.

Output Parameters

<i>a</i>	Array, size $\max(1, lda * n)$. On exit, the triangular matrix A . If <i>uplo</i> = 'U', the leading n -by- n upper triangular part of the array a contains the upper triangular matrix, and the strictly lower triangular part of a is not referenced. If <i>uplo</i> = 'L', the leading n -by- n lower triangular part of the array a contains the lower triangular matrix, and the strictly upper triangular part of a is not referenced.

Return Values

This function returns a value *info*.

If `info = 0`, the execution is successful.

If `info < 0`, the *i*-th parameter had an illegal value.

If `info = -1011`, memory allocation error occurred.

?tpqrt2

Computes a QR factorization of a real or complex "triangular-pentagonal" matrix, which is composed of a triangular block and a pentagonal block, using the compact WY representation for Q.

Syntax

```
lapack_int LAPACKE_stpqrt2 (int matrix_layout, lapack_int m, lapack_int n, lapack_int
l, float * a, lapack_int lda, float * b, lapack_int ldb, float * t, lapack_int ldt);

lapack_int LAPACKE_dtpqrt2 (int matrix_layout, lapack_int m, lapack_int n, lapack_int
l, double * a, lapack_int lda, double * b, lapack_int ldb, double * t, lapack_int
ldt);

lapack_int LAPACKE_ctpqrt2 (int matrix_layout, lapack_int m, lapack_int n, lapack_int
l, lapack_complex_float * a, lapack_int lda, lapack_complex_float * b, lapack_int ldb,
lapack_complex_float * t, lapack_int ldt );

lapack_int LAPACKE_ztpqrt2 (int matrix_layout, lapack_int m, lapack_int n, lapack_int
l, lapack_complex_double * a, lapack_int lda, lapack_complex_double * b, lapack_int
ldb, lapack_complex_double * t, lapack_int ldt );
```

Include Files

- `mkl.h`

Description

The input matrix *C* is an $(n+m)$ -by-*n* matrix

$$C = \begin{bmatrix} A \\ B \end{bmatrix} \leftarrow \begin{matrix} n \times n \text{ upper triangular} \\ m \times n \text{ pentagonal} \end{matrix}$$

where *A* is an *n*-by-*n* upper triangular matrix, and *B* is an *m*-by-*n* pentagonal matrix consisting of an $(m-1)$ -by-*n* rectangular matrix *B1* on top of an *l*-by-*n* upper trapezoidal matrix *B2*:

$$B = \begin{bmatrix} B1 \\ B2 \end{bmatrix} \leftarrow \begin{matrix} (m-1) \times n \text{ rectangular} \\ l \times n \text{ upper trapezoidal} \end{matrix}$$

The upper trapezoidal matrix *B2* consists of the first *l* rows of an *n*-by-*n* upper triangular matrix, where $0 \leq l \leq \min(m, n)$. If *l*=0, *B* is an *m*-by-*n* rectangular matrix. If *m*=*l*=*n*, *B* is upper triangular. The matrix *W* contains the elementary reflectors *H*(*i*) in the *i*th column below the diagonal (of *A*) in the $(n+m)$ -by-*n* input matrix *C* so that *W* can be represented as

$$W = \begin{bmatrix} I \\ V \end{bmatrix} \leftarrow \begin{matrix} n \times n \text{ identity} \\ m \times n \text{ pentagonal} \end{matrix}$$

Thus, V contains all of the information needed for W , and is returned in array b .

NOTE

V has the same form as B :

$$V = \begin{bmatrix} V1 \\ V2 \end{bmatrix} \leftarrow \begin{matrix} (m-l) \times n \text{ rectangular} \\ l \times n \text{ upper trapezoidal} \end{matrix}$$

The columns of V represent the vectors which define the $H(i)$ s.

The $(m+n)$ -by- $(m+n)$ block reflector H is then given by

$H = I - W^* T^* W^T$ for real flavors, and

$H = I - W^* T^* W^H$ for complex flavors

where W^T is the transpose of W , W^H is the conjugate transpose of W , and T is the upper triangular factor of the block reflector.

Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>m</i>	The total number of rows in the matrix B ($m \geq 0$).
<i>n</i>	The number of columns in B and the order of the triangular matrix A ($n \geq 0$).
<i>l</i>	The number of rows of the upper trapezoidal part of B ($\min(m, n) \geq l \geq 0$).
<i>a, b</i>	Arrays: <i>a</i> , size $\max(1, lda * n)$ contains the n -by- n upper triangular matrix A . <i>b</i> , size $\max(1, ldb * n)$ for column major and $\max(1, ldb * m)$ for row major, the pentagonal m -by- n matrix B . The first $(m-l)$ rows contain the rectangular $B1$ matrix, and the next l rows contain the upper trapezoidal $B2$ matrix.
<i>lda</i>	The leading dimension of <i>a</i> ; at least $\max(1, n)$.
<i>ldb</i>	The leading dimension of <i>b</i> ; at least $\max(1, m)$ for column major and $\max(1, n)$ for row major.
<i>ldt</i>	The leading dimension of <i>t</i> ; at least $\max(1, n)$.

Output Parameters

<i>a</i>	The elements on and above the diagonal of the array contain the upper triangular matrix <i>R</i> .
<i>b</i>	The pentagonal matrix <i>V</i> .
<i>t</i>	Array, size $\max(1, ldt * n)$. The upper <i>n</i> -by- <i>n</i> upper triangular factor <i>T</i> of the block reflector.

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* < 0 and *info* = -*i*, the *i*th argument had an illegal value.

If *info* = -1011, memory allocation error occurred.

?tprfb

Applies a real or complex "triangular-pentagonal" blocked reflector to a real or complex matrix, which is composed of two blocks.

Syntax

```
lapack_int LAPACKE_stprfb (int matrix_layout, char side, char trans, char direct, char storev, lapack_int m, lapack_int n, lapack_int k, lapack_int l, const float * v, lapack_int ldv, const float * t, lapack_int ldt, float * a, lapack_int lda, float * b, lapack_int ldb);
```

```
lapack_int LAPACKE_dtpfrfb (int matrix_layout, char side, char trans, char direct, char storev, lapack_int m, lapack_int n, lapack_int k, lapack_int l, const double * v, lapack_int ldv, const double * t, lapack_int ldt, double * a, lapack_int lda, double * b, lapack_int ldb);
```

```
lapack_int LAPACKE_ctprfb (int matrix_layout, char side, char trans, char direct, char storev, lapack_int m, lapack_int n, lapack_int k, lapack_int l, const lapack_complex_float * v, lapack_int ldv, const lapack_complex_float * t, lapack_int ldt, lapack_complex_float * a, lapack_int lda, lapack_complex_float * b, lapack_int ldb);
```

```
lapack_int LAPACKE_ztpfrfb (int matrix_layout, char side, char trans, char direct, char storev, lapack_int m, lapack_int n, lapack_int k, lapack_int l, const lapack_complex_double * v, lapack_int ldv, const lapack_complex_double * t, lapack_int ldt, lapack_complex_double * a, lapack_int lda, lapack_complex_double * b, lapack_int ldb);
```

Include Files

- mkl.h

Description

The ?tprfb routine applies a real or complex "triangular-pentagonal" block reflector H , H^T , or H^H from either the left or the right to a real or complex matrix *C*, which is composed of two blocks *A* and *B*.

The block *B* is *m*-by-*n*. If *side* = 'R', *A* is *m*-by-*k*, and if *side* = 'L', *A* is of size *k*-by-*n*.

$$\begin{array}{ll}
 \text{direct} = \text{'F'} & \text{direct} = \text{'B'} \\
 \text{side} = \text{'R'} & C = \begin{bmatrix} A & B \end{bmatrix} \quad C = \begin{bmatrix} B & A \end{bmatrix} \\
 \text{side} = \text{'L'} & C = \begin{bmatrix} A \\ B \end{bmatrix} \quad C = \begin{bmatrix} B \\ A \end{bmatrix}
 \end{array}$$

The pentagonal matrix V is composed of a rectangular block $V1$ and a trapezoidal block $V2$. The size of the trapezoidal block is determined by the parameter l , where $0 \leq l \leq k$. if $l=k$, the $V2$ block of V is triangular; if $l=0$, there is no trapezoidal block, thus $V = V1$ is rectangular.

$\text{direct} = \text{'F'}$	$\text{direct} = \text{'B'}$
$\text{storev} = \text{'C'}$	
$V = \begin{bmatrix} V1 \\ V2 \end{bmatrix}$	$V = \begin{bmatrix} V2 \\ V1 \end{bmatrix}$
$V2$ is upper trapezoidal (first l rows of k -by- k upper triangular)	$V2$ is lower trapezoidal (last l rows of k -by- k lower triangular matrix)
$\text{storev} = \text{'R'}$	
$V = \begin{bmatrix} V1 & V2 \end{bmatrix}$	$V = \begin{bmatrix} V2 & V1 \end{bmatrix}$
$V2$ is lower trapezoidal (first l columns of k -by- k lower triangular matrix)	$V2$ is upper trapezoidal (last l columns of k -by- k upper triangular matrix)

	$\text{side} = \text{'L'}$	$\text{side} = \text{'R'}$
$\text{storev} = \text{'C'}$	V is m -by- k	V is n -by- k
	$V2$ is l -by- k	$V2$ is l -by- k
$\text{storev} = \text{'R'}$	V is k -by- m	V is k -by- n
	$V2$ is k -by- l	$V2$ is k -by- l

Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>side</i>	= 'L': apply H , H^T , or H^H from the left, = 'R': apply H , H^T , or H^H from the right.
<i>trans</i>	= 'N': apply H (no transpose), = 'T': apply H^T (transpose), = 'C': apply H^H (conjugate transpose).
<i>direct</i>	Indicates how H is formed from a product of elementary reflectors: = 'F': $H = H(1) H(2) \dots H(k)$ (Forward),

= 'B': $H = H(k) \dots H(2) H(1)$ (Backward).

storev

Indicates how the vectors that define the elementary reflectors are stored:

= 'C': Columns,

= 'R': Rows.

m

The total number of rows in the matrix B ($m \geq 0$).

n

The number of columns in B ($n \geq 0$).

k

The order of the matrix T , which is the number of elementary reflectors whose product defines the block reflector. ($k \geq 0$)

l

The order of the trapezoidal part of V . ($k \geq l \geq 0$).

v

An array containing the pentagonal matrix v (the elementary reflectors $H(1), H(2), \dots, H(k)$). The size limitations depend on values of parameters *storev* and *side* as described in the following table

	<i>storev</i> = C		<i>storev</i> = R	
	<i>side</i> = L	<i>side</i> = R	<i>side</i> = L	<i>side</i> = R
Column major	$\max(1, l_{dv} * k)$	$\max(1, l_{dv} * k)$	$\max(1, l_{dv} * m)$	$\max(1, l_{dv} * n)$
Row major	$\max(1, l_{dv} * m)$	$\max(1, l_{dv} * n)$	$\max(1, l_{dv} * k)$	$\max(1, l_{dv} * k)$

ldv

The leading dimension of the array *v*. It should satisfy the following conditions:

	<i>storev</i> = C		<i>storev</i> = R	
	<i>side</i> = L	<i>side</i> = R	<i>side</i> = L	<i>side</i> = R
Column major	$\max(1, m)$	$\max(1, n)$	$\max(1, k)$	$\max(1, k)$
Row major	$\max(1, k)$	$\max(1, k)$	$\max(1, m)$	$\max(1, n)$

t

Array size $\max(1, l_{dt} * k)$. The triangular k -by- k matrix T in the representation of the block reflector.

ldt

The leading dimension of the array *t* ($l_{dt} \geq k$).

a

size should satisfy the following conditions:

k if *side* = 'R'.

	<i>side</i> = L	<i>side</i> = R
Column major	$\max(1, l_{da} * n)$	$\max(1, l_{da} * k)$
Row major	$\max(1, l_{da} * k)$	$\max(1, l_{da} * m)$

The k -by- n or m -by- k matrix A .

lda

The leading dimension of the array *a* should satisfy the following conditions:

	<i>side</i> = L	<i>side</i> = R
Column major	$\max(1, k)$	$\max(1, m)$
Row major	$\max(1, n)$	$\max(1, k)$

b

Array size at least $\max(1, \text{ldb} * n)$ for column major layout and $\max(1, \text{ldb} * m)$ for row major layout, the *m*-by-*n* matrix *B*.

ldb

The leading dimension of the array *b* ($\text{ldb} \geq \max(1, m)$ for column major layout and $\text{ldb} \geq \max(1, n)$ for row major layout).

Output Parameters

a

Contains the corresponding block of H^*C , $H^T * C$, $H^H * C$, C^*H , C^*H^T , or C^*H^H .

b

Contains the corresponding block of H^*C , $H^T * C$, $H^H * C$, C^*H , C^*H^T , or C^*H^H .

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* < 0, the *i*-th parameter had an illegal value.

If *info* = -1011, memory allocation error occurred.

?tpptf

Copies a triangular matrix from the standard packed format (TP) to the rectangular full packed format (TF).

Syntax

```
lapack_int LAPACKE_stpttf (int matrix_layout , char transr , char uplo , lapack_int n ,
const float * ap , float * arf );
```

```
lapack_int LAPACKE_dtpttf (int matrix_layout , char transr , char uplo , lapack_int n ,
const double * ap , double * arf );
```

```
lapack_int LAPACKE_ctpttf (int matrix_layout , char transr , char uplo , lapack_int n ,
const lapack_complex_float * ap , lapack_complex_float * arf );
```

```
lapack_int LAPACKE_ztpttf (int matrix_layout , char transr , char uplo , lapack_int n ,
const lapack_complex_double * ap , lapack_complex_double * arf );
```

Include Files

- mkl.h

Description

The routine copies a triangular matrix *A* from the standard packed format to the Rectangular Full Packed (RFP) format. For the description of the RFP format, see [Matrix Storage Schemes](#).

Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>transr</i>	= 'N': <i>arf</i> must be in the Normal format, = 'T': <i>arf</i> must be in the Transpose format (for <i>stpttf</i> and <i>dtpttf</i>), = 'C': <i>arf</i> must be in the Conjugate-transpose format (for <i>ctpttf</i> and <i>ztpttf</i>).
<i>uplo</i>	Specifies whether <i>A</i> is upper or lower triangular: = 'U': <i>A</i> is upper triangular, = 'L': <i>A</i> is lower triangular.
<i>n</i>	The order of the matrix <i>A</i> . $n \geq 0$.
<i>ap</i>	Array, size at least $\max(1, n*(n+1)/2)$. On entry, the upper or lower triangular matrix <i>A</i> , packed in a linear array. See Matrix Storage Schemes for more information.

Output Parameters

<i>arf</i>	Array, size at least $\max(1, n*(n+1)/2)$. On exit, the upper or lower triangular matrix <i>A</i> stored in the RFP format.

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

< 0: if *info* = -*i*, the *i*-th parameter had an illegal value.

If *info* = -1011, memory allocation error occurred.

?tpttr

Copies a triangular matrix from the standard packed format (TP) to the standard full format (TR).

Syntax

```
lapack_int LAPACKE_stpttr (int matrix_layout , char uplo , lapack_int n , const float *
ap , float * a , lapack_int lda );

lapack_int LAPACKE_dtptr (int matrix_layout , char uplo , lapack_int n , const double
* ap , double * a , lapack_int lda );

lapack_int LAPACKE_ctpttr (int matrix_layout , char uplo , lapack_int n , const
lapack_complex_float * ap , lapack_complex_float * a , lapack_int lda );

lapack_int LAPACKE_ztptr (int matrix_layout , char uplo , lapack_int n , const
lapack_complex_double * ap , lapack_complex_double * a , lapack_int lda );
```

Include Files

Description

The routine copies a triangular matrix A from the standard packed format to the standard full format.

Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (<code>LAPACK_ROW_MAJOR</code>) or column major (<code>LAPACK_COL_MAJOR</code>).
<i>uplo</i>	Specifies whether A is upper or lower triangular: = 'U': A is upper triangular, = 'L': A is lower triangular.
<i>n</i>	The order of the matrices ap and a . $n \geq 0$.
<i>ap</i>	Array, size at least $\max(1, n*(n+1)/2)$. (see Matrix Storage Schemes).
<i>lda</i>	The leading dimension of the array a . $lda \geq \max(1, n)$.

Output Parameters

<i>a</i>	Array, size $\max(1, lda*n)$. On exit, the triangular matrix A . If <i>uplo</i> = 'U', the leading n -by- n upper triangular part of the array a contains the upper triangular part of the matrix A , and the strictly lower triangular part of a is not referenced. If <i>uplo</i> = 'L', the leading n -by- n lower triangular part of the array a contains the lower triangular part of the matrix A , and the strictly upper triangular part of a is not referenced.

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* = $-i$, the i -th parameter had an illegal value.

If *info* = -1011, memory allocation error occurred.

?trttf

Copies a triangular matrix from the standard full format (TR) to the rectangular full packed format (TF).

Syntax

```
lapack_int LAPACKE_strttf (int matrix_layout , char transr , char uplo , lapack_int n ,
const float * a , lapack_int lda , float * arf );
```

```
lapack_int LAPACKE_dtrttf (int matrix_layout , char transr , char uplo , lapack_int n ,
const double * a , lapack_int lda , double * arf );
```

```
lapack_int LAPACKE_ctrttf (int matrix_layout , char transr , char uplo , lapack_int n ,
const lapack_complex_float * a , lapack_int lda , lapack_complex_float * arf );
```

```
lapack_int LAPACKE_ztrttf (int matrix_layout , char transr , char uplo , lapack_int n ,

<i>uplo</i>	Specifies whether <i>A</i> is upper or lower triangular: = 'U': <i>A</i> is upper triangular, = 'L': <i>A</i> is lower triangular.
<i>n</i>	The order of the matrix <i>A</i> . $n \geq 0$.
<i>a</i>	Array, size $\max(1, (lda*n))$. On entry, the triangular matrix <i>A</i> . If <i>uplo</i> = 'U', the leading <i>n</i> -by- <i>n</i> upper triangular part of the array <i>a</i> contains the upper triangular matrix, and the strictly lower triangular part of <i>a</i> is not referenced. If <i>uplo</i> = 'L', the leading <i>n</i> -by- <i>n</i> lower triangular part of the array <i>a</i> contains the lower triangular matrix, and the strictly upper triangular part of <i>a</i> is not referenced.
<i>lda</i>	The leading dimension of the array <i>a</i> . $lda \geq \max(1, n)$.

Output Parameters

<i>arf</i>	Array, size at least $\max(1, n*(n+1)/2)$. On exit, the upper or lower triangular matrix <i>A</i> stored in the RFP format.

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* < 0, the *i*-th parameter had an illegal value.

If *info* = -1011, memory allocation error occurred.

?trttp

Copies a triangular matrix from the standard full format (TR) to the standard packed format (TP) .

Syntax

```
lapack_int LAPACKE_strttp (int matrix_layout , char uplo , lapack_int n , const float *
a , lapack_int lda , float * ap );

lapack_int LAPACKE_dtrttp (int matrix_layout , char uplo , lapack_int n , const double
* a , lapack_int lda , double * ap );

lapack_int LAPACKE_ctrttp (int matrix_layout , char uplo , lapack_int n , const
lapack_complex_float * a , lapack_int lda , lapack_complex_float * ap );

lapack_int LAPACKE_ztrttp (int matrix_layout , char uplo , lapack_int n , const
lapack_complex_double * a , lapack_int lda , lapack_complex_double * ap );
```

Include Files

- mkl.h

Description

The routine copies a triangular matrix *A* from the standard full format to the standard packed format.

Input Parameters

<i>uplo</i>	Specifies whether <i>A</i> is upper or lower triangular: = 'U': <i>A</i> is upper triangular, = 'L': <i>A</i> is lower triangular.
<i>n</i>	The order of the matrix <i>A</i> , $n \geq 0$.
<i>a</i>	Array, size $\max(1, lda * n)$. On entry, the triangular matrix <i>A</i> . If <i>uplo</i> = 'U', the leading <i>n</i> -by- <i>n</i> upper triangular part of the array <i>a</i> contains the upper triangular matrix, and the strictly lower triangular part of <i>a</i> is not referenced. If <i>uplo</i> = 'L', the leading <i>n</i> -by- <i>n</i> lower triangular part of the array <i>a</i> contains the lower triangular matrix, and the strictly upper triangular part of <i>a</i> is not referenced.
<i>lda</i>	The leading dimension of the array <i>a</i> . $lda \geq \max(1, n)$.

Output Parameters

<i>ap</i>	Array, size at least $\max(1, n*(n+1)/2)$. On exit, the upper or lower triangular matrix <i>A</i> , packed columnwise in a linear array. (see Matrix Storage Schemes)

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* < 0, the *i*-th parameter had an illegal value.

If `info = -1011`, memory allocation error occurred.

zlacp2

Copies all or part of a real two-dimensional array to a complex array.

Syntax

```
lapack_int LAPACKE_zlacp2 (int matrix_layout , char uplo , lapack_int m , lapack_int
n , const float * a , lapack_int lda , lapack_complex_float * b , lapack_int ldb );
lapack_int LAPACKE_zlacp2 (int matrix_layout , char uplo , lapack_int m , lapack_int
n , const double * a , lapack_int lda , lapack_complex_double * b , lapack_int ldb );
```

Include Files

- mkl.h

Description

The routine copies all or part of a real matrix *A* to another matrix *B*.

Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>uplo</i>	Specifies the part of the matrix <i>A</i> to be copied to <i>B</i> . If <i>uplo</i> = 'U', the upper triangular part of <i>A</i> ; if <i>uplo</i> = 'L', the lower triangular part of <i>A</i> . Otherwise, all of the matrix <i>A</i> is copied.
<i>m</i>	The number of rows in the matrix <i>A</i> ($m \geq 0$).
<i>n</i>	The number of columns in <i>A</i> ($n \geq 0$).
<i>a</i>	Array, size at least $\max(1, lda \cdot n)$ for column major and $\max(1, lda \cdot m)$ for row major, contains the <i>m</i> -by- <i>n</i> matrix <i>A</i> . If <i>uplo</i> = 'U', only the upper triangle or trapezoid is accessed; if <i>uplo</i> = 'L', only the lower triangle or trapezoid is accessed.
<i>lda</i>	The leading dimension of <i>a</i> ; $lda \geq \max(1, m)$ for column major and $lda \geq \max(1, n)$ for row major.
<i>ldb</i>	The leading dimension of the output array <i>b</i> ; $ldb \geq \max(1, m)$ for column major and $ldb \geq \max(1, n)$ for row major.

Output Parameters

<i>b</i>	Array, size at least $\max(1, ldb \cdot n)$ for column major layout and $\max(1, ldb \cdot m)$ for row major layout, contains the <i>m</i> -by- <i>n</i> matrix <i>B</i> . On exit, $B = A$ in the locations specified by <i>uplo</i> .

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* < 0, the *i*-th parameter had an illegal value.

If *info* = -1011, memory allocation error occurred.

mkl_?tppack

Copies a triangular/symmetric matrix or submatrix from standard full format to standard packed format.

Syntax

```
lapack_int LAPACKE_mkl_stppack (int matrix_layout, char uplo, char trans, lapack_int n,
float* ap, lapack_int i, lapack_int j, lapack_int rows, lapack_int cols, const float*
a, lapack_int lda);
```

```
lapack_int LAPACKE_mkl_dtpack (int matrix_layout, char uplo, char trans, lapack_int n,
double* ap, lapack_int i, lapack_int j, lapack_int rows, lapack_int cols, const
double* a, lapack_int lda);
```

```
lapack_int LAPACKE_mkl_ctppack (int matrix_layout, char uplo, char trans, lapack_int n,
MKL_Complex8* ap, lapack_int i, lapack_int j, lapack_int rows, lapack_int cols, const
MKL_Complex8* a, lapack_int lda);
```

```
lapack_int LAPACKE_mkl_ztpack (int matrix_layout, char uplo, char trans, lapack_int n,
MKL_Complex16* ap, lapack_int i, lapack_int j, lapack_int rows, lapack_int cols, const
MKL_Complex16* a, lapack_int lda);
```

Include Files

- mkl.h

Description

The routine copies a triangular or symmetric matrix or its submatrix from standard full format to packed format

```
 $AP_{i:i+rows-1, j:j+cols-1} := op(A)$ 
```

Standard packed formats include:

- TP: triangular packed storage
- SP: symmetric indefinite packed storage
- HP: Hermitian indefinite packed storage
- PP: symmetric or Hermitian positive definite packed storage

Full formats include:

- GE: general
- TR: triangular
- SY: symmetric indefinite
- HE: Hermitian indefinite
- PO: symmetric or Hermitian positive definite

NOTE

Any elements of the copied submatrix rectangular outside of the triangular part of the matrix AP are skipped.

Input Parameters

<i>uplo</i>	Specifies whether the matrix AP is upper or lower triangular. If <i>uplo</i> = 'U', AP is upper triangular. If <i>uplo</i> = 'L': AP is lower triangular.
<i>trans</i>	Specifies whether or not the copied block of A is transposed or not. If <i>trans</i> = 'N', no transpose: $\text{op}(A) = A$. If <i>trans</i> = 'T', transpose: $\text{op}(A) = A^T$. If <i>trans</i> = 'C', conjugate transpose: $\text{op}(A) = A^H$. For real data this is the same as <i>trans</i> = 'T'.
<i>n</i>	The order of the matrix AP ; $n \geq 0$
<i>i, j</i>	Coordinates of the left upper corner of the destination submatrix in AP . If <i>uplo</i> ='U', $1 \leq i \leq j \leq n$. If <i>uplo</i> ='L', $1 \leq j \leq i \leq n$.
<i>rows</i>	Number of rows in the destination submatrix. $0 \leq \text{rows} \leq n - i + 1$.
<i>cols</i>	Number of columns in the destination submatrix. $0 \leq \text{cols} \leq n - j + 1$.
<i>a</i>	Pointer to the source submatrix. Array <i>a</i> contains the <i>rows</i> -by- <i>cols</i> submatrix stored as unpacked rows-by-columns if <i>trans</i> = 'N', or unpacked columns-by-rows if <i>trans</i> = 'T' or <i>trans</i> = 'C'. The size of <i>a</i> is

	<i>trans</i> = 'N'	<i>trans</i> ='T' or <i>trans</i> ='C'
<i>matrix_layout</i> = LAPACK_COL_MAJOR	<i>lda</i> * <i>cols</i>	<i>lda</i> * <i>rows</i>
<i>matrix_layout</i> = LAPACK_ROW_MAJOR	<i>lda</i> * <i>rows</i>	<i>lda</i> * <i>cols</i>

NOTE

If there are elements outside of the triangular part of AP , they are skipped and are not copied from *a*.

<i>lda</i>	The leading dimension of the array <i>a</i> .

	<i>trans</i> = 'N'	<i>trans</i> ='T' or <i>trans</i> ='C'
<i>matrix_layout</i> = LAPACK_COL_MAJOR	<i>lda</i> ≥ max(1, <i>rows</i>)	<i>lda</i> ≥ max(1, <i>cols</i>)
<i>matrix_layout</i> = LAPACK_ROW_MAJOR	<i>lda</i> ≥ max(1, <i>cols</i>)	<i>lda</i> ≥ max(1, <i>rows</i>)

Output Parameters

ap

Array of size at least $\max(1, n(n+1)/2)$. The array *ap* contains either the upper or the lower triangular part of the matrix *AP* (as specified by *uplo*) in packed storage (see [Matrix Storage Schemes](#)). The submatrix of *ap* from row *i* to row *i* + *rows* - 1 and column *j* to column *j* + *cols* - 1 is overwritten with a copy of the source matrix.

Return Values

This function returns a value *info*. If *info*=0, the execution is successful. If *info* = -*i*, the *i*-th parameter had an illegal value.

mkl_?tpunpack

Copies a triangular/symmetric matrix or submatrix from standard packed format to full format.

Syntax

```
lapack_int LAPACK_mkl_stpunpack ( int matrix_layout, char uplo, char trans,
    lapack_int n, const float* ap, lapack_int i, lapack_int j, lapack_int rows,
    lapack_int cols, float* a, lapack_int lda );

lapack_int LAPACK_mkl_dtpunpack ( int matrix_layout, char uplo, char trans,
    lapack_int n, const double* ap, lapack_int i, lapack_int j, lapack_int rows,
    lapack_int cols, double* a, lapack_int lda );

lapack_int LAPACK_mkl_ctpunpack ( int matrix_layout, char uplo, char trans,
    lapack_int n, const MKL_Complex8* ap, lapack_int i, lapack_int j, lapack_int rows,
    lapack_int cols, MKL_Complex8* a, lapack_int lda );

lapack_int LAPACK_mkl_ztpunpack ( int matrix_layout, char uplo, char trans,
    lapack_int n, const MKL_Complex16* ap, lapack_int i, lapack_int j, lapack_int rows,
    lapack_int cols, MKL_Complex16* a, lapack_int lda );
```

Include Files

- mkl.h

Description

The routine copies a triangular or symmetric matrix or its submatrix from standard packed format to full format.

$A := \text{op}(AP_{i:i+\text{rows}-1, j:j+\text{cols}-1})$

Standard packed formats include:

- TP: triangular packed storage
- SP: symmetric indefinite packed storage
- HP: Hermitian indefinite packed storage
- PP: symmetric or Hermitian positive definite packed storage

Full formats include:

- GE: general
- TR: triangular
- SY: symmetric indefinite
- HE: Hermitian indefinite
- PO: symmetric or Hermitian positive definite

NOTE

Any elements of the copied submatrix rectangular outside of the triangular part of AP are skipped.

Input Parameters

<i>uplo</i>	Specifies whether matrix AP is upper or lower triangular. If <i>uplo</i> = 'U', AP is upper triangular. If <i>uplo</i> = 'L': AP is lower triangular.
<i>trans</i>	Specifies whether or not the copied block of AP is transposed. If <i>trans</i> = 'N', no transpose: $\text{op}(AP) = AP$. If <i>trans</i> = 'T', transpose: $\text{op}(AP) = AP^T$. If <i>trans</i> = 'C', conjugate transpose: $\text{op}(AP) = AP^H$. For real data this is the same as <i>trans</i> = 'T'.
<i>n</i>	The order of the matrix AP ; $n \geq 0$.
<i>ap</i>	Array, size at least $\max(1, n(n+1)/2)$. The array <i>ap</i> contains either the upper or the lower triangular part of the matrix AP (as specified by <i>uplo</i>) in packed storage (see Matrix Storage Schemes). It is the source for the submatrix of AP from row i to row $i + \text{rows} - 1$ and column j to column $j + \text{cols} - 1$ to be copied.
<i>i, j</i>	Coordinates of left upper corner of the submatrix in AP to copy. If <i>uplo</i> ='U', $1 \leq i \leq j \leq n$. If <i>uplo</i> ='L', $1 \leq j \leq i \leq n$.
<i>rows</i>	Number of rows to copy. $0 \leq \text{rows} \leq n - i + 1$.
<i>cols</i>	Number of columns to copy. $0 \leq \text{cols} \leq n - j + 1$.
<i>lda</i>	The leading dimension of array <i>a</i> .

	<i>trans</i> = 'N'	<i>trans</i> ='T' or <i>trans</i> ='C'
<i>matrix_layout</i> = LAPACK_COL_MAJOR	<i>lda</i> ≥ max(1, <i>rows</i>)	<i>lda</i> ≥ max(1, <i>cols</i>)
<i>matrix_layout</i> = LAPACK_ROW_MAJOR	<i>lda</i> ≥ max(1, <i>cols</i>)	<i>lda</i> ≥ max(1, <i>rows</i>)

Output Parameters

a Pointer to the destination matrix. On exit, array *a* is overwritten with a copy of the unpacked *rows*-by-*cols* submatrix of *ap* unpacked rows-by-columns if *trans* = 'N', or unpacked columns-by-rows if *trans* = 'T' or *trans* = 'C'.
The size of *a* is

	<i>trans</i> = 'N'	<i>trans</i> ='T' or <i>trans</i> ='C'
<i>matrix_layout</i> = LAPACK_COL_MAJOR	<i>lda</i> * <i>cols</i>	<i>lda</i> * <i>rows</i>
<i>matrix_layout</i> = LAPACK_ROW_MAJOR	<i>lda</i> * <i>rows</i>	<i>lda</i> * <i>cols</i>

NOTE
If there are elements outside of the triangular part of *ap* indicated by *uplo*, they are skipped and are not copied to *a*.

Return Values

This function returns a value *info*. If *info*=0, the execution is successful. If *info* = -*i*, the *i*-th parameter had an illegal value.

Utility Functions and Routines

This section describes LAPACK utility functions and routines.

See Also

- [lsame](#) Tests two characters for equality regardless of the case.
- [lsamen](#) Tests two character strings for equality regardless of the case.
- [second/dsecnd](#) Returns elapsed time in seconds. Use to estimate real time between two calls to this function.

?lamch

Determines machine parameters for floating-point arithmetic.

Syntax

```
float LAPACKE_slamch (char cmach );
double LAPACKE_dlamch (char cmach );
```

Include Files

- mkl.h

Description

The function ?lamch determines single precision and double precision machine parameters.

Input Parameters

cmach Specifies the value to be returned by ?lamch:

- = 'E' or 'e', *val* = *eps*
- = 'S' or 's', *val* = *sfmin*
- = 'B' or 'b', *val* = *base*
- = 'P' or 'p', *val* = *eps*base*
- = 'n' or 'N', *val* = *t*
- = 'R' or 'r', *val* = *rnd*
- = 'M' or 'm', *val* = *emin*
- = 'U' or 'u', *val* = *rmin*
- = 'L' or 'l', *val* = *emax*
- = 'O' or 'o', *val* = *rmax*

where

- eps* = relative machine precision;
- sfmin* = safe minimum, such that $1/sfmin$ does not overflow;
- base* = base of the machine;
- prec* = $eps*base$;
- t* = number of (base) digits in the mantissa;
- rnd* = 1.0 when rounding occurs in addition, 0.0 otherwise;
- emin* = minimum exponent before (gradual) underflow;
- rmin* = $underflow\_threshold - base^{*(emin-1)}$;
- emax* = largest exponent before overflow;
- rmax* = $overflow\_threshold - (base^{*emax})*(1-eps)$.

NOTE

You can use a character string for *cmach* instead of a single character in order to make your code more readable. The first character of the string determines the value to be returned. For example, 'Precision' is interpreted as 'p'.

Output Parameters

val Value returned by the function.

Test Functions and Routines

This section describes LAPACK test functions and routines.

?lagge

Generates a general m -by- n matrix .

Syntax

```
lapack_int LAPACKE_slagge (int matrix_layout , lapack_int m , lapack_int n , lapack_int
kl , lapack_int ku , const float * d , float * a , lapack_int lda , lapack_int *
iseed );
```

```
lapack_int LAPACKE_dlagge (int matrix_layout , lapack_int m , lapack_int n , lapack_int
kl , lapack_int ku , const double * d , double * a , lapack_int lda , lapack_int *
iseed );
```

```
lapack_int LAPACKE_clagge (int matrix_layout , lapack_int m , lapack_int n , lapack_int
kl , lapack_int ku , const float * d , lapack_complex_float * a , lapack_int lda ,
lapack_int * iseed );
```

```
lapack_int LAPACKE_zlagge (int matrix_layout , lapack_int m , lapack_int n , lapack_int
kl , lapack_int ku , const double * d , lapack_complex_double * a , lapack_int lda ,
lapack_int * iseed );
```

Include Files

- mkl.h

Description

The routine generates a general m -by- n matrix A , by pre- and post- multiplying a real diagonal matrix D with random matrices U and V :

$$A := U^* D V,$$

where U and V are orthogonal for real flavors and unitary for complex flavors. The lower and upper bandwidths may then be reduced to kl and ku by additional orthogonal transformations.

Input Parameters

m	The number of rows of the matrix A ($m \geq 0$).
n	The number of columns of the matrix A ($n \geq 0$).
kl	The number of nonzero subdiagonals within the band of A ($0 \leq kl \leq m-1$).
ku	The number of nonzero superdiagonals within the band of A ($0 \leq ku \leq n-1$).
d	The array d with the dimension of $(\min(m, n))$ contains the diagonal elements of the diagonal matrix D .

<i>lda</i>	The leading dimension of the array <i>a</i> ($lda \geq m$) for column major layout and ($lda \geq n$) for row major layout.
<i>iseed</i>	The array <i>iseed</i> with the dimension of 4 contains the seed of the random number generator. The elements must be between 0 and 4095 and <i>iseed</i> must be odd.

Output Parameters

<i>a</i>	The array <i>a</i> with size at least $\max(1, lda * n)$ for column major layout and $\max(1, lda * m)$ for row major layout contains the generated <i>m</i> -by- <i>n</i> matrix <i>A</i> .
<i>iseed</i>	The array <i>iseed</i> contains the updated seed on exit.

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* < 0, the *i*-th parameter had an illegal value.

If *info* = -1011, memory allocation error occurred.

?laghe

Generates a complex Hermitian matrix .

Syntax

```
lapack_int LAPACKE_claghe (int matrix_layout , lapack_int n , lapack_int k , const
float * d , lapack_complex_float * a , lapack_int lda , lapack_int * iseed );
```

```
lapack_int LAPACKE_zlaghe (int matrix_layout , lapack_int n , lapack_int k , const
double * d , lapack_complex_double * a , lapack_int lda , lapack_int * iseed );
```

Include Files

- mkl.h

Description

The routine generates a complex Hermitian matrix *A*, by pre- and post- multiplying a real diagonal matrix *D* with random unitary matrix:

$$A := U * D * U^H$$

The semi-bandwidth may then be reduced to *k* by additional unitary transformations.

Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>n</i>	The order of the matrix <i>A</i> ($n \geq 0$).
<i>k</i>	The number of nonzero subdiagonals within the band of <i>A</i> ($0 \leq k \leq n-1$).

<i>d</i>	The array <i>d</i> with the dimension of (<i>n</i>) contains the diagonal elements of the diagonal matrix <i>D</i> .
<i>lda</i>	The leading dimension of the array <i>a</i> (<i>lda</i> ≥ <i>n</i>).
<i>iseed</i>	The array <i>iseed</i> with the dimension of 4 contains the seed of the random number generator. The elements must be between 0 and 4095 and <i>iseed</i> [3] must be odd.

Output Parameters

<i>a</i>	The array <i>a</i> of size at least max (1, <i>lda</i> * <i>n</i>) contains the generated <i>n</i> -by- <i>n</i> Hermitian matrix <i>D</i> .
<i>iseed</i>	The array <i>iseed</i> contains the updated seed on exit.

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* < 0, the *i*-th parameter had an illegal value.

If *info* = -1011, memory allocation error occurred.

?lagsy

Generates a symmetric matrix by pre- and post-multiplying a real diagonal matrix with a random unitary matrix .

Syntax

```
lapack_int LAPACKE_slagsy (int matrix_layout , lapack_int n , lapack_int k , const
float * d , float * a , lapack_int lda , lapack_int * iseed );
```

```
lapack_int LAPACKE_dlagsy (int matrix_layout , lapack_int n , lapack_int k , const
double * d , double * a , lapack_int lda , lapack_int * iseed );
```

```
lapack_int LAPACKE_clagsy (int matrix_layout , lapack_int n , lapack_int k , const
float * d , lapack_complex_float * a , lapack_int lda , lapack_int * iseed );
```

```
lapack_int LAPACKE_zlagsy (int matrix_layout , lapack_int n , lapack_int k , const
double * d , lapack_complex_double * a , lapack_int lda , lapack_int * iseed );
```

Include Files

- mkl.h

Description

The ?lagsy routine generates a symmetric matrix *A* by pre- and post- multiplying a real diagonal matrix *D* with a random matrix *U*:

$$A := U^T D U,$$

where *U* is orthogonal for real flavors and unitary for complex flavors. The semi-bandwidth may then be reduced to *k* by additional unitary transformations.

Input Parameters

<i>n</i>	The order of the matrix <i>A</i> ($n \geq 0$).
<i>k</i>	The number of nonzero subdiagonals within the band of <i>A</i> ($0 \leq k \leq n-1$).
<i>d</i>	The array <i>d</i> with the dimension of (<i>n</i>) contains the diagonal elements of the diagonal matrix <i>D</i> .
<i>lda</i>	The leading dimension of the array <i>a</i> ($lda \geq n$).
<i>iseed</i>	The array <i>iseed</i> with the dimension of 4 contains the seed of the random number generator. The elements must be between 0 and 4095 and <i>iseed</i> [3] must be odd.

Output Parameters

<i>a</i>	The array <i>aof</i> size max (1, <i>lda</i> * <i>n</i>) contains the generated symmetric <i>n</i> -by- <i>n</i> matrix <i>D</i> .
<i>iseed</i>	The array <i>iseed</i> contains the updated seed on exit.

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* < 0, the *i*-th parameter had an illegal value.

If *info* = -1011, memory allocation error occurred.

?latms

Generates a general m-by-n matrix with specific singular values.

Syntax

```
lapack_int LAPACKE_slatms (int matrix_layout, lapack_int m, lapack_int n, char dist,
lapack_int * iseed, char sym, float * d, lapack_int mode, float cond, float dmax,
lapack_int kl, lapack_int ku, char pack, float * a, lapack_int lda);

lapack_int LAPACKE_dlatms (int matrix_layout, lapack_int m, lapack_int n, char dist,
lapack_int * iseed, char sym, double * d, lapack_int mode, double cond, double dmax,
lapack_int kl, lapack_int ku, char pack, double * a, lapack_int lda);

lapack_int LAPACKE_clatms (int matrix_layout, lapack_int m, lapack_int n, char dist,
lapack_int * iseed, char sym, float * d, lapack_int mode, float cond, float dmax,
lapack_int kl, lapack_int ku, char pack, lapack_complex_float * a, lapack_int lda);

lapack_int LAPACKE_zlatms (int matrix_layout, lapack_int m, lapack_int n, char dist,
lapack_int * iseed, char sym, double * d, lapack_int mode, double cond, double dmax,
lapack_int kl, lapack_int ku, char pack, lapack_complex_double * a, lapack_int lda);
```

Include Files

- mkl.h

Description

The `?latms` routine generates random matrices with specified singular values, or symmetric/Hermitian matrices with specified eigenvalues for testing LAPACK programs.

It applies this sequence of operations:

1. Set the diagonal to d , where d is input or computed according to *mode*, *cond*, *dmax*, and *sym* as described in Input Parameters.
2. Generate a matrix with the appropriate band structure, by one of two methods:

Method A

 1. Generate a dense m -by- n matrix by multiplying d on the left and the right by random unitary matrices, then:
 2. Reduce the bandwidth according to kl and ku , using Householder transformations.

Method B:

Convert the bandwidth-0 (i.e., diagonal) matrix to a bandwidth-1 matrix using Givens rotations, "chasing" out-of-band elements back, much as in QR; then convert the bandwidth-1 to a bandwidth-2 matrix, etc.

Note that for reasonably small bandwidths (relative to m and n) this requires less storage, as a dense matrix is not generated. Also, for symmetric or Hermitian matrices, only one triangle is generated.

Method A is chosen if the bandwidth is a large fraction of the order of the matrix, and *lda* is at least m (so a dense matrix can be stored.) Method B is chosen if the bandwidth is small (less than $(1/2)*n$ for symmetric or Hermitian or less than $.3*n+m$ for nonsymmetric), or *lda* is less than m and not less than the bandwidth.

Pack the matrix if desired, using one of the methods specified by the *pack* parameter.

If Method B is chosen and band format is specified, then the matrix is generated in the band format and no repacking is necessary.

Input Parameters

<i>matrix_layout</i>	Specifies whether matrix storage layout is row major (LAPACK_ROW_MAJOR) or column major (LAPACK_COL_MAJOR).
<i>m</i>	The number of rows of the matrix A ($m \geq 0$).
<i>n</i>	The number of columns of the matrix A ($n \geq 0$).
<i>dist</i>	Specifies the type of distribution to be used to generate the random singular values or eigenvalues: • 'U': uniform distribution (0, 1) • 'S': symmetric uniform distribution (-1, 1) • 'N': normal distribution (0, 1)
<i>iseed</i>	Array with size 4. Specifies the seed of the random number generator. Values should lie between 0 and 4095 inclusive, and <i>iseed</i>[3] should be odd. The random number generator uses a linear congruential sequence limited to small

integers, and so should produce machine independent random numbers. The values of the array are modified, and can be used in the next call to `latms` to continue the same random number sequence.

sym

If *sym*='S' or 'H', the generated matrix is symmetric or Hermitian, with eigenvalues specified by *d*, *cond*, *mode*, and *dmax*; they can be positive, negative, or zero.

If *sym*='P', the generated matrix is symmetric or Hermitian, with eigenvalues (which are singular, non-negative values) specified by *d*, *cond*, *mode*, and *dmax*.

If *sym*='N', the generated matrix is nonsymmetric, with singular, non-negative values specified by *d*, *cond*, *mode*, and *dmax*.

d

Array, size (MIN(*m*, *n*))

This array is used to specify the singular values or eigenvalues of *A* (see the description of *sym*). If *mode*=0, then *d* is assumed to contain the eigenvalues or singular values, otherwise elements of *d* are computed according to *mode*, *cond*, and *dmax*.

mode

Describes how the singular/eigenvalues are specified.

- *mode* = 0: use *d* as input
- *mode* = 1: set $d[0] = 1$ and $d[1:n - 1] = 1.0/cond$
- *mode* = 2: set $d[0:n - 2] = 1$ and $d[n - 1] = 1.0/cond$
- *mode* = 3: set $d[i] = cond^{-i/(n - 1)}$
- *mode* = 4: set $d[i] = 1 - i/(n - 1) * (1 - 1/cond)$
- *mode* = 5: set elements of *d* to random numbers in the range (1/*cond*, 1) such that their logarithms are uniformly distributed.
- *mode* = 6: set elements of *d* to random numbers from same distribution as the rest of the matrix.

mode < 0 has the same meaning as ABS(*mode*), except that the order of the elements of *d* is reversed. Thus, if *mode* is positive, *d* has entries ranging from 1 to 1/*cond*, if negative, from 1/*cond* to 1.

If *sym*='S' or 'H', and *mode* is not 0, 6, nor -6, then the elements of *d* are also given a random sign (multiplied by +1 or -1).

cond

Used in setting *d* as described for the *mode* parameter. If used, $cond \geq 1$.

dmax

If *mode* is not -6, 0 nor 6, the contents of *d*, as computed according to *mode* and *cond*, are scaled by $dmax / \max(\text{abs}(d[i-1]))$; thus, the maximum absolute eigenvalue or singular value (the norm) is $\text{abs}(dmax)$.

NOTE

dmax need not be positive: if *dmax* is negative (or zero), *d* will be scaled by a negative number (or zero).

kl Specifies the lower bandwidth of the matrix. For example, $kl=0$ implies upper triangular, $kl=1$ implies upper Hessenberg, and kl being at least $m - 1$ means that the matrix has full lower bandwidth. kl must equal ku if the matrix is symmetric or Hermitian.

ku Specifies the upper bandwidth of the matrix. For example, $ku=0$ implies lower triangular, $ku=1$ implies lower Hessenberg, and ku being at least $n - 1$ means that the matrix has full upper bandwidth. kl must equal ku if the matrix is symmetric or Hermitian.

pack Specifies packing of matrix:

- 'N': no packing
- 'U': zero out all subdiagonal entries (if symmetric or Hermitian)
- 'L': zero out all superdiagonal entries (if symmetric or Hermitian)
- 'B': store the lower triangle in band storage scheme (only if matrix symmetric, Hermitian, or lower triangular)
- 'Q': store the upper triangle in band storage scheme (only if matrix symmetric, Hermitian, or upper triangular)
- 'Z': store the entire matrix in band storage scheme (pivoting can be provided for by using this option to store A in the trailing rows of the allocated storage)

Using these options, the various LAPACK packed and banded storage schemes can be obtained:

	'Z'	'B'	'Q'	'C'	'R'
GB: general band	x				
PB: symmetric positive definite band		x	x		
SB: symmetric band		x	x		
HB: Hermitian band		x	x		
TB: triangular band		x	x		
PP: symmetric positive definite packed				x	x
SP: symmetric packed				x	x
HP: Hermitian packed				x	x
TP: triangular packed				x	x

If two calls to `?latms` differ only in the *pack* parameter, they generate mathematically equivalent matrices.

lda *lda* specifies the first dimension of *a* as declared in the calling program.

If *pack*='N', 'U', 'L', 'C', or 'R', then *lda* must be at least *m* for column major or at least *n* for row major.

If *pack*='B' or 'Q', then *lda* must be at least $\text{MIN}(kl, m - 1)$ (which is equal to $\text{MIN}(ku, n - 1)$).

If *pack*='Z', *lda* must be large enough to hold the packed array: $\text{MIN}(ku, n - 1) + \text{MIN}(kl, m - 1) + 1$.

Output Parameters

iseed The array *iseed* contains the updated seed.

d The array *d* contains the updated seed.

NOTE

The array *d* is not modified if *mode* = 0.

a Array of size *lda* by *n*.

The array *a* contains the generated *m*-by-*n* matrix *A*.

a is first generated in full (unpacked) form, and then packed, if so specified by *pack*. Thus, the first *m* elements of the first *n* columns are always modified. If *pack* specifies a packed or banded storage scheme, all *lda* elements of the first *n* columns are modified; the elements of the array which do not correspond to elements of the generated matrix are set to zero.

Return Values

This function returns a value *info*.

If *info* = 0, the execution is successful.

If *info* < 0, the *i*-th parameter had an illegal value.

If *info* = -1011, memory allocation error occurred.

If *info* = 2, cannot scale to *dmax* (maximum singular value is 0).

If *info* = 3, error return from [lagge](#), [?laghe](#), or [lagsy](#).

ScaLAPACK Routines

This chapter describes the Intel® Math Kernel Library implementation of routines from the ScaLAPACK package for distributed-memory architectures. Routines are supported for both real and complex dense and band matrices to perform the tasks of solving systems of linear equations, solving linear least-squares problems, eigenvalue and singular value problems, as well as performing a number of related computational tasks.

Intel MKL ScaLAPACK routines are written in FORTRAN 77 with exception of a few utility routines written in C to exploit the IEEE arithmetic. All routines are available in all precision types: single precision, double precision, complexm, and double complex precision. See the `mkl_scalapack.h` header file for C declarations of ScaLAPACK routines.

NOTE

ScaLAPACK routines are provided only for Intel® 64 or Intel® Many Integrated Core architectures.

Sections in this chapter include descriptions of ScaLAPACK [computational routines](#) that perform distinct computational tasks, as well as [driver routines](#) for solving standard types of problems in one call.

The `<install_directory>/examples/scalapackf` directory contains sample code demonstrating the use of ScaLAPACK routines.

Generally, ScaLAPACK runs on a network of computers using MPI as a message-passing layer and a set of prebuilt communication subprograms (BLACS), as well as a set of BLAS optimized for the target architecture. Intel MKL version of ScaLAPACK is optimized for Intel® processors. For the detailed system and environment requirements, see *Intel® MKL Release Notes* and *Intel® MKL User's Guide*.

For full reference on ScaLAPACK routines and related information, see [\[SLUG\]](#).

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Overview

The model of the computing environment for ScaLAPACK is represented as a one-dimensional array of processes (for operations on band or tridiagonal matrices) or also a two-dimensional process grid (for operations on dense matrices). To use ScaLAPACK, all global matrices or vectors should be distributed on this array or grid prior to calling the ScaLAPACK routines.

ScaLAPACK uses the two-dimensional block-cyclic data distribution as a layout for dense matrix computations. This distribution provides good work balance between available processors, and also gives the opportunity to use BLAS Level 3 routines for optimal local computations. Information about the data distribution that is required to establish the mapping between each global matrix and its corresponding process and memory location is contained in the array called the *array descriptor* associated with each global matrix. The size of the array descriptor is denoted as *dlen_*.

Let A be a two-dimensional block cyclicly distributed matrix with the array descriptor array *desca*. The meaning of each array descriptor element depends on the type of the matrix A . The tables [Array descriptor for dense matrices](#) and [Array descriptor for narrow-band and tridiagonal matrices](#) describe the meaning of each element for the different types of matrices.

Array descriptor for dense matrices (*dlen_=9*)

Element Name	Stored in	Description	Element Index Number
<i>dtype_a</i>	<i>desca[dtype_]</i>	Descriptor type (=1 for dense matrices).	0
<i>ctxt_a</i>	<i>desca[ctxt_]</i>	BLACS context handle for the process grid.	1
<i>m_a</i>	<i>desca[m_]</i>	Number of rows in the global matrix A .	2
<i>n_a</i>	<i>desca[n_]</i>	Number of columns in the global matrix A .	3
<i>mb_a</i>	<i>desca[mb_]</i>	Row blocking factor.	4
<i>nb_a</i>	<i>desca[nb_]</i>	Column blocking factor.	5
<i>rsrc_a</i>	<i>desca[rsrc_]</i>	Process row over which the first row of the global matrix A is distributed.	6
<i>csrc_a</i>	<i>desca[csrc_]</i>	Process column over which the first column of the global matrix A is distributed.	7
<i>lld_a</i>	<i>desca[lld_]</i>	Leading dimension of the local matrix A .	8

Array descriptor for narrow-band and tridiagonal matrices (*dlen_=7*)

Element Name	Stored in	Description	Element Index Number
<i>dtype_a</i>	<i>desca[dtype_]</i>	Descriptor type <i>dtype_a</i>=501: 1-by-P grid, <i>dtype_a</i>=502: P-by-1 grid.	0
<i>ctxt_a</i>	<i>desca[ctxt_]</i>	BLACS context handle indicating the BLACS process grid over which the global matrix A is distributed. The context itself is global, but the handle (the integer value) can vary.	1
<i>n_a</i>	<i>desca[n_]</i>	The size of the matrix dimension being distributed.	2
<i>nb_a</i>	<i>desca[nb_]</i>	The blocking factor used to distribute the distributed dimension of the matrix A .	3
<i>src_a</i>	<i>desca[src_]</i>	The process row or column over which the first row or column of the matrix A is distributed.	4
<i>lld_a</i>	<i>desca[lld_]</i>	The leading dimension of the local matrix storing the local blocks of the distributed matrix A . The minimum value of <i>lld_a</i> depends on <i>dtype_a</i> . <i>dtype_a</i>=501: $lld_a \geq \max(\text{size of undistributed dimension}, 1)$, <i>dtype_a</i>=502: $lld_a \geq \max(nb_a, 1)$.	5
Not applicable		Reserved for future use.	6

Similar notations are used for different matrices. For example: *lld_b* is the leading dimension of the local matrix storing the local blocks of the distributed matrix B and *dtype_z* is the type of the global matrix Z .

The number of rows and columns of a global dense matrix that a particular process in a grid receives after data distributing is denoted by $LOC_r()$ and $LOC_c()$, respectively. To compute these numbers, you can use the ScaLAPACK tool routine `numroc`.

After the block-cyclic distribution of global data is done, you may choose to perform an operation on a submatrix $\text{sub}(A)$ of the global matrix A defined by the following 6 values (for dense matrices):

m	The number of rows of $\text{sub}(A)$
n	The number of columns of $\text{sub}(A)$

<i>a</i>	A pointer to the local matrix containing the entire global matrix <i>A</i>
<i>ia</i>	The row index of sub(<i>A</i>) in the global matrix <i>A</i>
<i>ja</i>	The column index of sub(<i>A</i>) in the global matrix <i>A</i>
<i>desca</i>	The array descriptor for the global matrix <i>A</i>

Optimization Notice

Notice revision #20110804

Routine Naming Conventions

For each routine introduced in this chapter, you can use the ScaLAPACK name. The naming convention for ScaLAPACK routines is similar to that used for LAPACK routines. A general rule is that each routine name in ScaLAPACK, which has an LAPACK equivalent, is simply the LAPACK name prefixed by initial letter *p*.

ScaLAPACK names have the structure *p?yyzzz* or *p?yyzz*, which is described below.

The initial letter *p* is a distinctive prefix of ScaLAPACK routines and is present in each such routine.

The second symbol *?* indicates the data type:

<i>s</i>	real, single precision
<i>d</i>	real, double precision
<i>c</i>	complex, single precision
<i>z</i>	complex, double precision

The second and third letters *yy* indicate the matrix type as:

<i>ge</i>	general
<i>gb</i>	general band
<i>gg</i>	a pair of general matrices (for a generalized problem)
<i>dt</i>	general tridiagonal (diagonally dominant-like)
<i>db</i>	general band (diagonally dominant-like)
<i>po</i>	symmetric or Hermitian positive-definite
<i>pb</i>	symmetric or Hermitian positive-definite band
<i>pt</i>	symmetric or Hermitian positive-definite tridiagonal
<i>sy</i>	symmetric

st	symmetric tridiagonal (real)
he	Hermitian
or	orthogonal
tr	triangular (or quasi-triangular)
tz	trapezoidal
un	unitary

For computational routines, the last three letters **zzz** indicate the computation performed and have the same meaning as for LAPACK routines.

For driver routines, the last two letters **zz** or three letters **zzz** have the following meaning:

sv	a <i>simple</i> driver for solving a linear system
svx	an <i>expert</i> driver for solving a linear system
ls	a driver for solving a linear least squares problem
ev	a simple driver for solving a symmetric eigenvalue problem
evd	a simple driver for solving an eigenvalue problem using a divide and conquer algorithm
evx	an expert driver for solving a symmetric eigenvalue problem
svd	a driver for computing a singular value decomposition
gvx	an expert driver for solving a generalized symmetric definite eigenvalue problem

Simple driver here means that the driver just solves the general problem, whereas an *expert* driver is more versatile and can also optionally perform some related computations (such, for example, as refining the solution and computing error bounds after the linear system is solved).

Computational Routines

In the sections that follow, the descriptions of ScaLAPACK computational routines are given. These routines perform distinct computational tasks that can be used for:

- [Solving Systems of Linear Equations](#)
- [Orthogonal Factorizations and LLS Problems](#)
- [Symmetric Eigenproblems](#)
- [Nonsymmetric Eigenproblems](#)
- [Singular Value Decomposition](#)
- [Generalized Symmetric-Definite Eigenproblems](#)

See also the respective [driver routines](#).

Linear Equations

ScaLAPACK supports routines for the systems of equations with the following types of matrices:

- general
- general banded

- general diagonally dominant-like banded (including general tridiagonal)
- symmetric or Hermitian positive-definite
- symmetric or Hermitian positive-definite banded
- symmetric or Hermitian positive-definite tridiagonal

A *diagonally dominant-like* matrix is defined as a matrix for which it is known in advance that pivoting is not required in the *LU* factorization of this matrix.

For the above matrix types, the library includes routines for performing the following computations: *factoring* the matrix; *equilibrating* the matrix; *solving* a system of linear equations; *estimating the condition number* of a matrix; *refining* the solution of linear equations and computing its error bounds; *inverting* the matrix. Note that for some of the listed matrix types only part of the computational routines are provided (for example, routines that refine the solution are not provided for band or tridiagonal matrices). See [Table “Computational Routines for Systems of Linear Equations”](#) for full list of available routines.

To solve a particular problem, you can either call two or more computational routines or call a corresponding [driver routine](#) that combines several tasks in one call. Thus, to solve a system of linear equations with a general matrix, you can first call `p?getrf` (*LU* factorization) and then `p?getrs` (computing the solution). Then, you might wish to call `p?gerfs` to refine the solution and get the error bounds. Alternatively, you can just use the driver routine `p?gesvx` which performs all these tasks in one call.

[Table “Computational Routines for Systems of Linear Equations”](#) lists the ScaLAPACK computational routines for factorizing, equilibrating, and inverting matrices, estimating their condition numbers, solving systems of equations with real matrices, refining the solution, and estimating its error.

Computational Routines for Systems of Linear Equations

Matrix type, storage scheme	Factorize matrix	Equilibrate matrix	Solve system	Condition number	Estimate error	Invert matrix
general (partial pivoting)	p?getrf	p?geequ	p?getrs	p?gecon	p?gerfs	p?getri
general band (partial pivoting)	p?gbtrf		p?gbtrs			
general band (no pivoting)	p?dbtrf		p?dbtrs			
general tridiagonal (no pivoting)	p?dttrf		p?dttrs			
symmetric/Hermitian positive-definite	p?potrf	p?poequ	p?potrs	p?pocon	p?porfs	p?potri
symmetric/Hermitian positive-definite, band	p?pbtrf		p?pbtrs			
symmetric/Hermitian positive-definite, tridiagonal	p?pttrf		p?pttrs			
triangular			p?trtrs	p?trcon	p?trrfs	p?trtri

In this table ? stands for s (single precision real), d (double precision real), c (single precision complex), or z (double precision complex).

Routines for Matrix Factorization

This section describes the ScaLAPACK routines for matrix factorization. The following factorizations are supported:

- LU factorization of general matrices
- LU factorization of diagonally dominant-like matrices
- Cholesky factorization of real symmetric or complex Hermitian positive-definite matrices

You can compute the factorizations using full and band storage of matrices.

[p?getrf](#)

Computes the LU factorization of a general m-by-n distributed matrix.

Syntax

```
void psgetrf (MKL_INT *m , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , MKL_INT *ipiv , MKL_INT *info );

void pdgetrf (MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_INT *ipiv , MKL_INT *info );

void pcgetrf (MKL_INT *m , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_INT *ipiv , MKL_INT *info );

void pzgetrf (MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_INT *ipiv , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The `p?getrf` function forms the LU factorization of a general m -by- n distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$ as

$$A = P * L * U$$

where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if $m > n$) and U is upper triangular (upper trapezoidal if $m < n$). L and U are stored in $\text{sub}(A)$.

The function uses partial pivoting, with row interchanges.

Input Parameters

<i>m</i>	(global) The number of rows in the distributed matrix $\text{sub}(A)$; $m \geq 0$.
<i>n</i>	(global) The number of columns in the distributed matrix $\text{sub}(A)$; $n \geq 0$.
<i>a</i>	(local) Pointer into the local memory to an array of local size $lld\_a * LOCC(ja+n-1)$. Contains the local pieces of the distributed matrix $\text{sub}(A)$ to be factored.
<i>ia, ja</i>	(global) The row and column indices in the global matrix A indicating the first row and the first column of the matrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix A .

Output Parameters

<i>a</i>	Overwritten by local pieces of the factors L and U from the factorization $A = P * L * U$. The unit diagonal elements of L are not stored.
<i>ipiv</i>	(local) Array of size $LOCr(m\_a) + mb\_a$. Contains the pivoting information: local row i was interchanged with global row $ipiv[i-1]$. This array is tied to the distributed matrix A .
<i>info</i>	(global) If $info=0$, the execution is successful.

$info < 0$: if the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

If $info = i > 0$, $u_{ia+i, ja+j-1}$ is 0. The factorization has been completed, but the factor U is exactly singular. Division by zero will occur if you use the factor U for solving a system of linear equations.

See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

p?gbtrf

Computes the LU factorization of a general n -by- n banded distributed matrix.

Syntax

```
void psgbtrf (MKL_INT *n , MKL_INT *bwl , MKL_INT *bwu , float *a , MKL_INT *ja ,
MKL_INT *desca , MKL_INT *ipiv , float *af , MKL_INT *laf , float *work , MKL_INT
*lwork , MKL_INT *info );

void pdgbtrf (MKL_INT *n , MKL_INT *bwl , MKL_INT *bwu , double *a , MKL_INT *ja ,
MKL_INT *desca , MKL_INT *ipiv , double *af , MKL_INT *laf , double *work , MKL_INT
*lwork , MKL_INT *info );

void pcgbtrf (MKL_INT *n , MKL_INT *bwl , MKL_INT *bwu , MKL_Complex8 *a , MKL_INT
*ja , MKL_INT *desca , MKL_INT *ipiv , MKL_Complex8 *af , MKL_INT *laf , MKL_Complex8
*work , MKL_INT *lwork , MKL_INT *info );

void pzgbtrf (MKL_INT *n , MKL_INT *bwl , MKL_INT *bwu , MKL_Complex16 *a , MKL_INT
*ja , MKL_INT *desca , MKL_INT *ipiv , MKL_Complex16 *af , MKL_INT *laf ,
MKL_Complex16 *work , MKL_INT *lwork , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The `p?gbtrf` function computes the LU factorization of a general n -by- n real/complex banded distributed matrix $A(1:n, ja:ja+n-1)$ using partial pivoting with row interchanges.

The resulting factorization is not the same factorization as returned from the LAPACK function `?gbtrf`. Additional permutations are performed on the matrix for the sake of parallelism.

The factorization has the form

$$A(1:n, ja:ja+n-1) = P * L * U * Q$$

where P and Q are permutation matrices, and L and U are banded lower and upper triangular matrices, respectively. The matrix Q represents reordering of columns for the sake of parallelism, while P represents reordering of rows for numerical stability using classic partial pivoting.

Notice revision #20110804

Input Parameters

n	(global) The number of rows and columns in the distributed submatrix $A(1:n, ja:ja+n-1)$; $n \geq 0$.
bwl	(global) The number of sub-diagonals within the band of A ($0 \leq bwl \leq n-1$).
bwu	(global) The number of super-diagonals within the band of A ($0 \leq bwu \leq n-1$).
a	(local) Pointer into the local memory to an array of local size $lld\_a * LOCc(ja+n-1)$ where $lld\_a \geq 2*bwl + 2*bwu + 1$. Contains the local pieces of the n -by- n distributed banded matrix $A(1:n, ja:ja+n-1)$ to be factored.
ja	(global) The index in the global matrix A indicating the start of the matrix to be operated on (which may be either all of A or a submatrix of A).
$desca$	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix A . If $dtype\_a = 501$, then $dlen\_ \geq 7$; else if $dtype\_a = 1$, then $dlen\_ \geq 9$.
laf	(local) The size of the array af . Must be $laf \geq (nb\_a + bwu) * (bwl + bwu) + 6 * (bwl + bwu) * (bwl + 2 * bwu)$. If laf is not large enough, an error code will be returned and the minimum acceptable size will be returned in $af[0]$.
$work$	(local) Same type as a . Workspace array of size $lwork$.
$lwork$	(local or global) The size of the $work$ array ($lwork \geq 1$). If $lwork$ is too small, the minimal acceptable size will be returned in $work[0]$ and an error code is returned.

Output Parameters

a	On exit, this array contains details of the factorization. Note that additional permutations are performed on the matrix, so that the factors returned are different from those returned by LAPACK.

<i>ipiv</i>	(local) array. The size of <i>ipiv</i> must be $\geq nb\_a$. Contains pivot indices for local factorizations. Note that you <i>should not alter</i> the contents of this array between factorization and solve.
<i>af</i>	(local) Array of size <i>laf</i> . Auxiliary fill-in space. The fill-in space is created in a call to the factorization function <i>p?gbtrf</i> and is stored in <i>af</i> . Note that if a linear system is to be solved using <i>p?gbtrs</i> after the factorization function, <i>af</i> must not be altered after the factorization.
<i>work</i> [0]	On exit, <i>work</i> [0] contains the minimum value of <i>lwork</i> required.
<i>info</i>	(global) If <i>info</i> =0, the execution is successful. <i>info</i> < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j</i> - 1, had an illegal value, then <i>info</i> = -(<i>i</i> *100+ <i>j</i>); if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> . <i>info</i> > 0: If <i>info</i> = <i>k</i> ≤ NPROCS, the submatrix stored on processor <i>info</i> and factored locally was not nonsingular, and the factorization was not completed. If <i>info</i> = <i>k</i> > NPROCS, the submatrix stored on processor <i>info</i> -NPROCS representing interactions with other processors was not nonsingular, and the factorization was not completed.

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

p?dbtrf

Computes the LU factorization of a n-by-n diagonally dominant-like banded distributed matrix.

Syntax

```
void psdbtrf (MKL_INT *n , MKL_INT *bwl , MKL_INT *bwu , float *a , MKL_INT *ja ,
MKL_INT *desca , float *af , MKL_INT *laf , float *work , MKL_INT *lwork , MKL_INT
*info );

void pddbtrf (MKL_INT *n , MKL_INT *bwl , MKL_INT *bwu , double *a , MKL_INT *ja ,
MKL_INT *desca , double *af , MKL_INT *laf , double *work , MKL_INT *lwork , MKL_INT
*info );

void pcdbrf (MKL_INT *n , MKL_INT *bwl , MKL_INT *bwu , MKL_Complex8 *a , MKL_INT

Description

The `p?dbtrf` function computes the LU factorization of a n -by- n real/complex diagonally dominant-like banded distributed matrix $A(1:n, ja:ja+n-1)$ without pivoting.

NOTE

A matrix is called *diagonally dominant-like* if pivoting is not required for LU to be numerically stable.

Note that the resulting factorization is not the same factorization as returned from LAPACK. Additional permutations are performed on the matrix for the sake of parallelism.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

n	(global) The number of rows and columns in the distributed submatrix $A(1:n, ja:ja+n-1)$; $n \geq 0$.
bwl	(global) The number of sub-diagonals within the band of A ($0 \leq bwl \leq n-1$).
bwu	(global) The number of super-diagonals within the band of A ($0 \leq bwu \leq n-1$).
a	(local) Pointer into the local memory to an array of local size $lld\_a * LOCc(ja+n-1)$. Contains the local pieces of the n -by- n distributed banded matrix $A(1:n, ja:ja+n-1)$ to be factored.
ja	(global) The index in the global matrix A indicating the start of the matrix to be operated on (which may be either all of A or a submatrix of A).
$desca$	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix A . If $dtype\_a = 501$, then $dlen\_ \geq 7$; else if $dtype\_a = 1$, then $dlen\_ \geq 9$.
laf	(local) The size of the array af .

Must be $laf \geq NB * (bwl + bwu) + 6 * (\max(bwl, bwu))^2$.

If laf is not large enough, an error code will be returned and the minimum acceptable size will be returned in $af[0]$.

work

(local) Workspace array of size *lwork*.

lwork

(local or global) The size of the *work* array, must be $lwork \geq (\max(bwl, bwu))^2$. If *lwork* is too small, the minimal acceptable size will be returned in $work[0]$ and an error code is returned.

Output Parameters

a

On exit, this array contains details of the factorization. Note that additional permutations are performed on the matrix, so that the factors returned are different from those returned by LAPACK.

af

(local)

Array of size *laf*.

Auxiliary fill-in space. The fill-in space is created in a call to the factorization function `p?dbtrf` and is stored in *af*.

Note that if a linear system is to be solved using `p?dbtrs` after the factorization function, *af* must not be altered after the factorization.

work[0]

On exit, *work[0]* contains the minimum value of *lwork* required for optimum performance.

info

(global)

If *info*=0, the execution is successful.

info < 0:

If the *i*-th argument is an array and the *j*-th entry, indexed *j* - 1, had an illegal value, then *info* = -(*i**100+*j*); if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

info > 0:

If *info* = *k* ≤ NPROCS, the submatrix stored on processor *info* and factored locally was not diagonally dominant-like, and the factorization was not completed.

If *info* = *k* > NPROCS, the submatrix stored on processor *info*-NPROCS representing interactions with other processors was not nonsingular, and the factorization was not completed.

Notice revision #20110804

Input Parameters

n	(global) The number of rows and columns to be operated on, that is, the order of the distributed submatrix $A(1:n, ja:ja+n-1)$ ($n \geq 0$).
dl, d, du	(local) Pointers to the local arrays of size nb_a each. On entry, the array dl contains the local part of the global vector storing the subdiagonal elements of the matrix. Globally, $dl[0]$ is not referenced, and dl must be aligned with d. On entry, the array d contains the local part of the global vector storing the diagonal elements of the matrix. On entry, the array du contains the local part of the global vector storing the super-diagonal elements of the matrix. $du[n-1]$ is not referenced, and du must be aligned with d.

<i>ja</i>	(global) The index in the global matrix <i>A</i> indicating the start of the matrix to be operated on (which may be either all of <i>A</i> or a submatrix of <i>A</i>).
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> . If <i>dtype_a</i> = 501, then <i>dlen_</i> ≥ 7; else if <i>dtype_a</i> = 1, then <i>dlen_</i> ≥ 9.
<i>laf</i>	(local) The size of the array <i>af</i> . Must be <i>laf</i> ≥ 2*(NB+2) . If <i>laf</i> is not large enough, an error code will be returned and the minimum acceptable size will be returned in <i>af</i> [0].
<i>work</i>	(local) Same type as <i>d</i> . Workspace array of size <i>lwork</i> .
<i>lwork</i>	(local or global) The size of the <i>work</i> array, must be at least <i>lwork</i> ≥ 8*NPCOL.

Output Parameters

<i>dl, d, du</i>	On exit, overwritten by the information containing the factors of the matrix.
<i>af</i>	(local) Array of size <i>laf</i> . Auxiliary fill-in space. The fill-in space is created in a call to the factorization function <i>p?dttrf</i> and is stored in <i>af</i> . Note that if a linear system is to be solved using <i>p?dttrs</i> after the factorization function, <i>af</i> must not be altered.
<i>work</i> [0]	On exit, <i>work</i> [0] contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	(global) If <i>info</i> =0, the execution is successful. <i>info</i> < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j</i> - 1, had an illegal value, then <i>info</i> = -(<i>i</i> *100+ <i>j</i>); if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> . <i>info</i> > 0: If <i>info</i> = <i>k</i> ≤ NPROCS, the submatrix stored on processor <i>info</i> and factored locally was not diagonally dominant-like, and the factorization was not completed. If <i>info</i> = <i>k</i> > NPROCS, the submatrix stored on processor <i>info</i> -NPROCS representing interactions with other processors was not nonsingular, and the factorization was not completed.

p?potrf

Computes the Cholesky factorization of a symmetric (Hermitian) positive-definite distributed matrix.

Syntax

```
void pspotrf (char *uplo , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info );

void pdpotrf (char *uplo , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info );

void pcpotrf (char *uplo , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info );

void pzpotrf (char *uplo , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The `p?potrf` function computes the Cholesky factorization of a real symmetric or complex Hermitian positive-definite distributed n -by- n matrix $A(ia:ia+n-1, ja:ja+n-1)$, denoted below as $\text{sub}(A)$.

The factorization has the form

$\text{sub}(A) = U^H * U$ if `uplo='U'`, or

$\text{sub}(A) = L * L^H$ if `uplo='L'`

where L is a lower triangular matrix and U is upper triangular.

Input Parameters

<code>uplo</code>	(global) Indicates whether the upper or lower triangular part of $\text{sub}(A)$ is stored. Must be 'U' or 'L'. If <code>uplo = 'U'</code> , the array <code>a</code> stores the upper triangular part of the matrix $\text{sub}(A)$ that is factored as $U^H * U$. If <code>uplo = 'L'</code> , the array <code>a</code> stores the lower triangular part of the matrix $\text{sub}(A)$ that is factored as $L * L^H$.
<code>n</code>	(global) The order of the distributed matrix $\text{sub}(A)$ ($n \geq 0$).
<code>a</code>	(local) Pointer into the local memory to an array of size <code>lld_a * LOCc(ja+n-1)</code> . On entry, this array contains the local pieces of the n -by- n symmetric/Hermitian distributed matrix $\text{sub}(A)$ to be factored. Depending on <code>uplo</code> , the array <code>a</code> contains either the upper or the lower triangular part of the matrix $\text{sub}(A)$ (see <code>uplo</code>).
<code>ia, ja</code>	(global) The row and column indices in the global matrix A indicating the first row and the first column of the matrix $\text{sub}(A)$, respectively.

desca (global and local) array of size *dlen_*. The array descriptor for the distributed matrix *A*.

Output Parameters

a The upper or lower triangular part of *a* is overwritten by the Cholesky factor *U* or *L*, as specified by *uplo*.

info (global) .

If *info*=0, the execution is successful;

info < 0: if the *i*-th argument is an array, and the *j*-th entry, indexed *j* - 1, had an illegal value, then *info* = -(*i**100+*j*); if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

If *info* = *k* > 0, the leading minor of order *k*, *A*(*ia:ia+k-1*, *ja:ja+k-1*), is not positive-definite, and the factorization could not be completed.

Routines for Solving Systems of Linear Equations

This section describes the ScaLAPACK routines for solving systems of linear equations. Before calling most of these routines, you need to factorize the matrix of your system of equations (see [Routines for Matrix Factorization](#) in this chapter). However, the factorization is not necessary if your system of equations has a triangular matrix.

p?getrs

Solves a system of distributed linear equations with a general square matrix, using the LU factorization computed by p?getrf.

Syntax

```
void psgetrs (char *trans , MKL_INT *n , MKL_INT *nrhs , float *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_INT *ipiv , float *b , MKL_INT *ib , MKL_INT *jb ,
MKL_INT *descb , MKL_INT *info );

void pdgetrs (char *trans , MKL_INT *n , MKL_INT *nrhs , double *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_INT *ipiv , double *b , MKL_INT *ib , MKL_INT *jb ,
MKL_INT *descb , MKL_INT *info );

void pcgetrs (char *trans , MKL_INT *n , MKL_INT *nrhs , MKL_Complex8 *a , MKL_INT
*ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *ipiv , MKL_Complex8 *b , MKL_INT *ib ,
MKL_INT *jb , MKL_INT *descb , MKL_INT *info );

void pzgetrs (char *trans , MKL_INT *n , MKL_INT *nrhs , MKL_Complex16 *a , MKL_INT
*ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *ipiv , MKL_Complex16 *b , MKL_INT *ib ,
MKL_INT *jb , MKL_INT *descb , MKL_INT *info );
```

Include Files

Description

The `p?getrs` function solves a system of distributed linear equations with a general n -by- n distributed matrix $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$ using the LU factorization computed by `p?getrf`.

The system has one of the following forms specified by *trans*:

$\text{sub}(A)*X = \text{sub}(B)$ (no transpose),

$\text{sub}(A)^T*X = \text{sub}(B)$ (transpose),

$\text{sub}(A)^H*X = \text{sub}(B)$ (conjugate transpose),

where $\text{sub}(B) = B(\text{ib}:\text{ib}+n-1, \text{jb}:\text{jb}+\text{nrhs}-1)$.

Before calling this function, you must call `p?getrf` to compute the LU factorization of $\text{sub}(A)$.

Input Parameters

<i>trans</i>	(global) Must be 'N' or 'T' or 'C'. Indicates the form of the equations: If <i>trans</i> = 'N', then $\text{sub}(A)*X = \text{sub}(B)$ is solved for X . If <i>trans</i> = 'T', then $\text{sub}(A)^T*X = \text{sub}(B)$ is solved for X . If <i>trans</i> = 'C', then $\text{sub}(A)^H*X = \text{sub}(B)$ is solved for X .
<i>n</i>	(global) The number of linear equations; the order of the matrix $\text{sub}(A)$ ($n \geq 0$).
<i>nrhs</i>	(global) The number of right hand sides; the number of columns of the distributed matrix $\text{sub}(B)$ ($\text{nrhs} \geq 0$).
<i>a, b</i>	(global) Pointers into the local memory to arrays of local sizes $\text{lld}_a * \text{LOCc}(\text{ja}+n-1)$ and $\text{lld}_b * \text{LOCc}(\text{jb}+\text{nrhs}-1)$, respectively.

On entry, the array *a* contains the local pieces of the factors *L* and *U* from the factorization $\text{sub}(A) = P * L * U$; the unit diagonal elements of *L* are not stored. On entry, the array *b* contains the right hand sides $\text{sub}(B)$.

<i>ia, ja</i>	(global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the matrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .
<i>ipiv</i>	(local) Array of size of $LOCr(m\_a) + mb\_a$. Contains the pivoting information: local row <i>i</i> of the matrix was interchanged with the global row <i>ipiv</i> [<i>i</i> -1]. This array is tied to the distributed matrix <i>A</i> .
<i>ib, jb</i>	(global) The row and column indices in the global matrix <i>B</i> indicating the first row and the first column of the matrix $\text{sub}(B)$, respectively.
<i>descb</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>B</i> .

Output Parameters

<i>b</i>	On exit, overwritten by the solution distributed matrix <i>X</i> .
<i>info</i>	If <i>info</i> =0, the execution is successful. <i>info</i> < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j</i> - 1, had an illegal value, then <i>info</i> = -(<i>i</i> *100+ <i>j</i>); if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

Description

The `pzgbtrs` function solves a system of distributed linear equations with a general band distributed matrix $\text{sub}(A) = A(1:n, ja:ja+n-1)$ using the LU factorization computed by `pzgbtrf`.

The system has one of the following forms specified by `trans`:

$\text{sub}(A)*X = \text{sub}(B)$ (no transpose),

$\text{sub}(A)^T*X = \text{sub}(B)$ (transpose),

$\text{sub}(A)^H*X = \text{sub}(B)$ (conjugate transpose),

where $\text{sub}(B) = B(ib:ib+n-1, 1:nrhs)$.

Before calling this function, you must call `pzgbtrf` to compute the LU factorization of $\text{sub}(A)$.

Input Parameters

<code>trans</code>	(global) Must be 'N' or 'T' or 'C'. Indicates the form of the equations: If <code>trans</code> = 'N', then $\text{sub}(A)*X = \text{sub}(B)$ is solved for X . If <code>trans</code> = 'T', then $\text{sub}(A)^T*X = \text{sub}(B)$ is solved for X . If <code>trans</code> = 'C', then $\text{sub}(A)^H*X = \text{sub}(B)$ is solved for X .
<code>n</code>	(global) The number of linear equations; the order of the distributed matrix $\text{sub}(A)$ ($n \geq 0$).
<code>bwl</code>	(global) The number of sub-diagonals within the band of A ($0 \leq bwl \leq n-1$).
<code>bwu</code>	(global) The number of super-diagonals within the band of A ($0 \leq bwu \leq n-1$).
<code>nrhs</code>	(global) The number of right hand sides; the number of columns of the distributed matrix $\text{sub}(B)$ ($nrhs \geq 0$).
<code>a, b</code>	(global) Pointers into the local memory to arrays of local sizes $lld\_a*LOCc(ja+n-1)$ and $lld\_b*LOCc(nrhs)$, respectively. The array <code>a</code> contains details of the LU factorization of the distributed band matrix A . On entry, the array <code>b</code> contains the local pieces of the right hand sides $B(ib:ib+n-1, 1:nrhs)$.
<code>ja</code>	(global) The index in the global matrix A indicating the start of the matrix to be operated on (which may be either all of A or a submatrix of A).

<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> . If <i>dtype_a</i> = 501, then <i>dlen_</i> ≥ 7; else if <i>dtype_a</i> = 1, then <i>dlen_</i> ≥ 9.
<i>ib</i>	(global) The index in the global matrix <i>A</i> indicating the start of the matrix to be operated on (which may be either all of <i>A</i> or a submatrix of <i>A</i>).
<i>descb</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> . If <i>dtype_b</i> = 502, then <i>dlen_</i> ≥ 7; else if <i>dtype_b</i> = 1, then <i>dlen_</i> ≥ 9.
<i>laf</i>	(local) The size of the array <i>af</i> . Must be $laf \geq nb\_a * (bwl + bwu) + 6 * (bwl + bwu) * (bwl + 2 * bwu)$. If <i>laf</i> is not large enough, an error code will be returned and the minimum acceptable size will be returned in <i>af</i> [0].
<i>work</i>	(local) Same type as <i>a</i> . Workspace array of size <i>lwork</i> .
<i>lwork</i>	(local or global) The size of the <i>work</i> array, must be at least $lwork \geq nrhs * (nb\_a + 2 * bwl + 4 * bwu)$.

Output Parameters

<i>ipiv</i>	(local) array. The size of <i>ipiv</i> must be ≥ <i>nb_a</i> . Contains pivot indices for local factorizations. Note that you should not alter the contents of this array between factorization and solve.
<i>b</i>	On exit, overwritten by the local pieces of the solution distributed matrix <i>X</i> .
<i>af</i>	(local) Array of size <i>laf</i> . Auxiliary Fill-in space. The fill-in space is created in a call to the factorization function <i>p?gbtrf</i> and is stored in <i>af</i> . Note that if a linear system is to be solved using <i>p?gbtrs</i> after the factorization function, <i>af</i> must not be altered after the factorization.
<i>work</i> [0]	On exit, <i>work</i> [0] contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	If <i>info</i> =0, the execution is successful. <i>info</i> < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j</i> - 1, had an illegal value, then <i>info</i> = -(<i>i</i> *100+ <i>j</i>); if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

Description

The p?dbtrs function solves for X one of the systems of equations:

$\text{sub}(A) * X = \text{sub}(B),$
 $(\text{sub}(A))^T * X = \text{sub}(B),$ or
 $(\text{sub}(A))^H * X = \text{sub}(B),$

where $\text{sub}(A) = A(1:n, ja:ja+n-1)$ is a diagonally dominant-like banded distributed matrix, and $\text{sub}(B)$ denotes the distributed matrix $B(ib:ib+n-1, 1:nrhs)$.

This function uses the LU factorization computed by p?dbtrf.

Input Parameters

<i>trans</i>	(global) Must be 'N' or 'T' or 'C'. Indicates the form of the equations: If <i>trans</i> = 'N', then $\text{sub}(A) * X = \text{sub}(B)$ is solved for X . If <i>trans</i> = 'T', then $(\text{sub}(A))^T * X = \text{sub}(B)$ is solved for X . If <i>trans</i> = 'C', then $(\text{sub}(A))^H * X = \text{sub}(B)$ is solved for X .
<i>n</i>	(global) The order of the distributed matrix $\text{sub}(A)$ ($n \geq 0$).
<i>bwl</i>	(global) The number of subdiagonals within the band of A

	($0 \leq bwl \leq n-1$).
<i>bwu</i>	(global) The number of superdiagonals within the band of <i>A</i> ($0 \leq bwu \leq n-1$).
<i>nrhs</i>	(global) The number of right hand sides; the number of columns of the distributed matrix sub(<i>B</i>) ($nrhs \geq 0$).
<i>a, b</i>	(local) Pointers into the local memory to arrays of local sizes $lld\_a * LOCC(ja+n-1)$ and $lld\_b * LOCC(nrhs)$, respectively. On entry, the array <i>a</i> contains details of the <i>LU</i> factorization of the band matrix <i>A</i> , as computed by <code>p?dbtrf</code> . On entry, the array <i>b</i> contains the local pieces of the right hand side distributed matrix sub(<i>B</i>).
<i>ja</i>	(global) The index in the global matrix <i>A</i> indicating the start of the matrix to be operated on (which may be either all of <i>A</i> or a submatrix of <i>A</i>).
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> . If <i>dtype_a</i> = 501, then $dlen_ \geq 7$; else if <i>dtype_a</i> = 1, then $dlen_ \geq 9$.
<i>ib</i>	(global) The row index in the global matrix <i>B</i> indicating the first row of the matrix to be operated on (which may be either all of <i>B</i> or a submatrix of <i>B</i>).
<i>descb</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>B</i> . If <i>dtype_b</i> = 502, then $dlen_ \geq 7$; else if <i>dtype_b</i> = 1, then $dlen_ \geq 9$.
<i>af, work</i>	(local) Arrays of size <i>laf</i> and <i>lwork</i> , respectively The array <i>af</i> contains auxiliary fill-in space. The fill-in space is created in a call to the factorization function <code>p?dbtrf</code> and is stored in <i>af</i> . The array <i>work</i> is a workspace array.
<i>laf</i>	(local) The size of the array <i>af</i> . Must be $laf \geq NB * (bwl + bwu) + 6 * (\max(bwl, bwu))^2$. If <i>laf</i> is not large enough, an error code will be returned and the minimum acceptable size will be returned in <i>af</i> [0].
<i>lwork</i>	(local or global) The size of the array <i>work</i> , must be at least $lwork \geq (\max(bwl, bwu))^2$.

Output Parameters

<i>b</i>	On exit, this array contains the local pieces of the solution distributed matrix <i>X</i> .
<i>work</i> [0]	On exit, <i>work</i> [0] contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	If <i>info</i>=0, the execution is successful. <i>info</i> < 0: If the <i>i</i>-th argument is an array and the <i>j</i>-th entry, indexed <i>j</i> - 1, had an illegal value, then <i>info</i> = -(<i>i</i>*100+<i>j</i>); if the <i>i</i>-th argument is a scalar and had an illegal value, then <i>info</i> = -<i>i</i>.

Description

The `p?dttrs` function solves for *X* one of the systems of equations:

$\text{sub}(A) * X = \text{sub}(B)$,
 $(\text{sub}(A))^T * X = \text{sub}(B)$, or
 $(\text{sub}(A))^H * X = \text{sub}(B)$,

where $\text{sub}(A) = A(1:n, ja:ja+n-1)$ is a diagonally dominant-like tridiagonal distributed matrix, and $\text{sub}(B)$ denotes the distributed matrix $B(ib:ib+n-1, 1:nrhs)$.

This function uses the *LU* factorization computed by `p?dttrf`.

Input Parameters

<i>trans</i>	(global) Must be 'N' or 'T' or 'C'. Indicates the form of the equations: If <i>trans</i> = 'N', then $\text{sub}(A)*X = \text{sub}(B)$ is solved for X. If <i>trans</i> = 'T', then $(\text{sub}(A))^T * X = \text{sub}(B)$ is solved for X. If <i>trans</i> = 'C', then $(\text{sub}(A))^H * X = \text{sub}(B)$ is solved for X.
<i>n</i>	(global) The order of the distributed matrix $\text{sub}(A)$ ($n \geq 0$).
<i>nrhs</i>	(global) The number of right hand sides; the number of columns of the distributed matrix $\text{sub}(B)$ ($nrhs \geq 0$).
<i>dl, d, du</i>	(local) Pointers to the local arrays of size <i>nb_a</i> each. On entry, these arrays contain details of the factorization. Globally, <i>dl</i>[0] and <i>du</i>[<i>n</i>-1] are not referenced; <i>dl</i> and <i>du</i> must be aligned with <i>d</i>.
<i>ja</i>	(global) The index in the global matrix A indicating the start of the matrix to be operated on (which may be either all of A or a submatrix of A).
<i>desca</i>	(global and local) array of size <i>dlen_</i>. The array descriptor for the distributed matrix A. If <i>dtype_a</i> = 501 or <i>dtype_a</i> = 502, then <i>dlen_</i> $\geq$ 7; else if <i>dtype_a</i> = 1, then <i>dlen_</i> $\geq$ 9.
<i>b</i>	(local) Same type as <i>d</i>. Pointer into the local memory to an array of local size <i>lld_b</i>*<i>LOCc</i>(<i>nrhs</i>) On entry, the array <i>b</i> contains the local pieces of the <i>n</i>-by-<i>nrhs</i> right hand side distributed matrix $\text{sub}(B)$.
<i>ib</i>	(global) The row index in the global matrix B indicating the first row of the matrix to be operated on (which may be either all of B or a submatrix of B).
<i>descb</i>	(global and local) array of size <i>dlen_</i>. The array descriptor for the distributed matrix B. If <i>dtype_b</i> = 502, then <i>dlen_</i> $\geq$ 7; else if <i>dtype_b</i> = 1, then <i>dlen_</i> $\geq$ 9.
<i>af, work</i>	(local) Arrays of size <i>laf</i> and (<i>lwork</i>), respectively. The array <i>af</i> contains auxiliary fill-in space. The fill-in space is created in a call to the factorization function <i>p?dttrf</i> and is stored in <i>af</i>. If a linear system is to be solved using <i>p?dttrs</i> after the factorization function, <i>af</i> must not be altered. The array <i>work</i> is a workspace array.
<i>laf</i>	(local) The size of the array <i>af</i> .

Must be $laf \geq NB * (bwl + bwu) + 6 * (bwl + bwu) * (bwl + 2 * bwu)$.

If laf is not large enough, an error code will be returned and the minimum acceptable size will be returned in $af[0]$.

$lwork$ (local or global) The size of the array $work$, must be at least $lwork \geq 10 * NPCOL + 4 * nrhs$.

Output Parameters

b On exit, this array contains the local pieces of the solution distributed matrix X .

$work[0]$ On exit, $work[0]$ contains the minimum value of $lwork$ required for optimum performance.

$info$ If $info=0$, the execution is successful. $info < 0$:
If the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then $info = -(i * 100 + j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

Description

The `p?potrs` function solves for X a system of distributed linear equations in the form:

$$\text{sub}(A) * X = \text{sub}(B) ,$$

where $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$ is an n -by- n real symmetric or complex Hermitian positive definite distributed matrix, and $\text{sub}(B)$ denotes the distributed matrix $B(ib:ib+n-1, jb:jb+nrhs-1)$.

This function uses Cholesky factorization

$$\text{sub}(A) = U^H * U, \text{ or } \text{sub}(A) = L * L^H$$

computed by `p?potrf`.

Input Parameters

<i>uplo</i>	(global) Must be 'U' or 'L'. If <i>uplo</i> = 'U', upper triangle of sub(<i>A</i>) is stored; If <i>uplo</i> = 'L', lower triangle of sub(<i>A</i>) is stored.
<i>n</i>	(global) The order of the distributed matrix sub(<i>A</i>) ($n \geq 0$).
<i>nrhs</i>	(global) The number of right hand sides; the number of columns of the distributed matrix sub(<i>B</i>) ($nrhs \geq 0$).
<i>a, b</i>	(local) Pointers into the local memory to arrays of local sizes <i>lld_a</i> * <i>LOCc</i> (<i>ja</i> + <i>n</i> -1) and <i>lld_b</i> * <i>LOCc</i> (<i>jb</i> + <i>nrhs</i> -1), respectively. The array <i>a</i> contains the factors <i>L</i> or <i>U</i> from the Cholesky factorization sub(<i>A</i>) = <i>L</i> * <i>L</i> ^H or sub(<i>A</i>) = <i>U</i> ^H * <i>U</i> , as computed by <code>p?potrf</code> . On entry, the array <i>b</i> contains the local pieces of the right hand sides sub(<i>B</i>).
<i>ia, ja</i>	(global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the matrix sub(<i>A</i>), respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .
<i>ib, jb</i>	(global) The row and column indices in the global matrix <i>B</i> indicating the first row and the first column of the matrix sub(<i>B</i>), respectively.
<i>descb</i>	(local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>B</i> .

Output Parameters

<i>b</i>	Overwritten by the local pieces of the solution matrix <i>X</i> .
<i>info</i>	If <i>info</i> =0, the execution is successful. <i>info</i> < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j</i> - 1, had an illegal value, then <i>info</i> = -(<i>i</i> *100+ <i>j</i>); if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

Description

The `p?pbtrs` function solves for X a system of distributed linear equations in the form:

$$\text{sub}(A) * X = \text{sub}(B) ,$$

where $\text{sub}(A) = A(1:n, ja:ja+n-1)$ is an n -by- n real symmetric or complex Hermitian positive definite distributed band matrix, and $\text{sub}(B)$ denotes the distributed matrix $B(ib:ib+n-1, 1:nrhs)$.

This function uses Cholesky factorization

$$\text{sub}(A) = P * U^H * U * P^T, \text{ or } \text{sub}(A) = P * L * L^H * P^T$$

computed by `p?pbtrf`.

Input Parameters

<i>uplo</i>	(global) Must be 'U' or 'L'. If <i>uplo</i> = 'U', upper triangle of $\text{sub}(A)$ is stored; If <i>uplo</i> = 'L', lower triangle of $\text{sub}(A)$ is stored.
<i>n</i>	(global) The order of the distributed matrix $\text{sub}(A)$ ($n \geq 0$).
<i>bw</i>	(global) The number of superdiagonals of the distributed matrix if <i>uplo</i> = 'U', or the number of subdiagonals if <i>uplo</i> = 'L' ($bw \geq 0$).
<i>nrhs</i>	(global) The number of right hand sides; the number of columns of the distributed matrix $\text{sub}(B)$ ($nrhs \geq 0$).
<i>a, b</i>	(local) Pointers into the local memory to arrays of local sizes $lld\_a * LOCc(ja+n-1)$ and $lld\_b * LOCc(nrhs-1)$, respectively. The array <i>a</i> contains the permuted triangular factor U or L from the Cholesky factorization $\text{sub}(A) = P * U^H * U * P^T$, or $\text{sub}(A) = P * L * L^H * P^T$ of the band matrix A , as returned by <code>p?pbtrf</code> .

	On entry, the array <i>b</i> contains the local pieces of the <i>n</i> -by- <i>nrhs</i> right hand side distributed matrix <i>sub(B)</i> .
<i>ja</i>	(global) The index in the global matrix <i>A</i> indicating the start of the matrix to be operated on (which may be either all of <i>A</i> or a submatrix of <i>A</i>).
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> . If <i>dtype_a</i> = 501, then <i>dlen_</i> ≥ 7; else if <i>dtype_a</i> = 1, then <i>dlen_</i> ≥ 9.
<i>ib</i>	(global) The row index in the global matrix <i>B</i> indicating the first row of the matrix <i>sub(B)</i> .
<i>descb</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>B</i> . If <i>dtype_b</i> = 502, then <i>dlen_</i> ≥ 7; else if <i>dtype_b</i> = 1, then <i>dlen_</i> ≥ 9.
<i>af, work</i>	(local) Arrays, same type as <i>a</i> . The array <i>af</i> is of size <i>laf</i> . It contains auxiliary fill-in space. The fill-in space is created in a call to the factorization function p?dbtrf and is stored in <i>af</i> . The array <i>work</i> is a workspace array of size <i>lwork</i> .
<i>laf</i>	(local) The size of the array <i>af</i> . Must be <i>laf</i> ≥ <i>nrhs</i> * <i>bw</i> . If <i>laf</i> is not large enough, an error code will be returned and the minimum acceptable size will be returned in <i>af</i> [0].
<i>lwork</i>	(local or global) The size of the array <i>work</i> , must be at least <i>lwork</i> ≥ <i>bw</i> ² .

Output Parameters

<i>b</i>	On exit, if <i>info</i> =0, this array contains the local pieces of the <i>n</i> -by- <i>nrhs</i> solution distributed matrix <i>X</i> .
<i>work</i> [0]	On exit, <i>work</i> [0] contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	If <i>info</i> =0, the execution is successful. <i>info</i> < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j</i> - 1, had an illegal value, then <i>info</i> = -(<i>i</i> *100+ <i>j</i>); if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

Description

The p?pttrs function solves for X a system of distributed linear equations in the form:

$$\text{sub}(A) * X = \text{sub}(B) ,$$

where $\text{sub}(A) = A(1:n, ja:ja+n-1)$ is an n -by- n real symmetric or complex Hermitian positive definite tridiagonal distributed matrix, and $\text{sub}(B)$ denotes the distributed matrix $B(ib:ib+n-1, 1:nrhs)$.

This function uses the factorization

$$\text{sub}(A) = P * L * D * L^H * P^T, \text{ or } \text{sub}(A) = P * U^H * D * U * P^T$$

computed by p?pttrf.

Input Parameters

<i>uplo</i>	(global, used in complex flavors only) Must be 'U' or 'L'. If <i>uplo</i> = 'U', upper triangle of $\text{sub}(A)$ is stored; If <i>uplo</i> = 'L', lower triangle of $\text{sub}(A)$ is stored.
<i>n</i>	(global) The order of the distributed matrix $\text{sub}(A)$ ($n \geq 0$).
<i>nrhs</i>	(global) The number of right hand sides; the number of columns of the distributed matrix $\text{sub}(B)$ ($nrhs \geq 0$).
<i>d, e</i>	(local) Pointers into the local memory to arrays of size <i>nb_a</i> each.

These arrays contain details of the factorization as returned by `p?pttrf`

<i>ja</i>	(global) The index in the global matrix <i>A</i> indicating the start of the matrix to be operated on (which may be either all of <i>A</i> or a submatrix of <i>A</i>).
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> . If <i>dtype_a</i> = 501 or <i>dtype_a</i> = 502, then <i>dlen_</i> ≥ 7; else if <i>dtype_a</i> = 1, then <i>dlen_</i> ≥ 9.
<i>b</i>	(local) Same type as <i>d</i> , <i>e</i> . Pointer into the local memory to an array of local size <i>lld_b</i> * <i>LOCc</i> (<i>nrhs</i>). On entry, the array <i>b</i> contains the local pieces of the <i>n</i> -by- <i>nrhs</i> right hand side distributed matrix sub(<i>B</i>).
<i>ib</i>	(global) The row index in the global matrix <i>B</i> indicating the first row of the matrix to be operated on (which may be either all of <i>B</i> or a submatrix of <i>B</i>).
<i>descb</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>B</i> . If <i>dtype_b</i> = 502, then <i>dlen_</i> ≥ 7; else if <i>dtype_b</i> = 1, then <i>dlen_</i> ≥ 9.
<i>af, work</i>	(local) Arrays of size <i>laf</i> and (<i>lwork</i>), respectively. The array <i>af</i> contains auxiliary fill-in space. The fill-in space is created in a call to the factorization function <code>p?pttrf</code> and is stored in <i>af</i> . The array <i>work</i> is a workspace array.
<i>laf</i>	(local) The size of the array <i>af</i> . Must be <i>laf</i> ≥ <i>nb_a</i> +2. If <i>laf</i> is not large enough, an error code is returned and the minimum acceptable size will be returned in <i>af</i> [0].
<i>lwork</i>	(local or global) The size of the array <i>work</i> , must be at least <i>lwork</i> ≥ (10+2* <i>min</i> (100, <i>nrhs</i>))* <i>NPCOL</i> +4* <i>nrhs</i> .

Output Parameters

<i>b</i>	On exit, this array contains the local pieces of the solution distributed matrix <i>X</i> .
<i>work</i> [0])	On exit, <i>work</i> [0] contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	If <i>info</i> =0, the execution is successful. <i>info</i> < 0:

if the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

MKL_INT *ib , MKL_INT *jb , MKL_INT *descb , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The p?trtrs function solves for X one of the following systems of linear equations:

$\text{sub}(A)*X = \text{sub}(B)$,

$(\text{sub}(A))^T*X = \text{sub}(B)$, or

$(\text{sub}(A))^H*X = \text{sub}(B)$,

where $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$ is a triangular distributed matrix of order n , and $\text{sub}(B)$ denotes the distributed matrix $B(ib:ib+n-1, jb:jb+nrhs-1)$.

A check is made to verify that $\text{sub}(A)$ is nonsingular.

Input Parameters

<i>uplo</i>	(global) Must be 'U' or 'L'. Indicates whether $\text{sub}(A)$ is upper or lower triangular: If <i>uplo</i> = 'U', then $\text{sub}(A)$ is upper triangular. If <i>uplo</i> = 'L', then $\text{sub}(A)$ is lower triangular.
<i>trans</i>	(global) Must be 'N' or 'T' or 'C'. Indicates the form of the equations: If <i>trans</i> = 'N', then $\text{sub}(A)*X = \text{sub}(B)$ is solved for X .

If $trans = 'T'$, then $sub(A)^T X = sub(B)$ is solved for X .

If $trans = 'C'$, then $sub(A)^H X = sub(B)$ is solved for X .

diag (global) Must be 'N' or 'U'.

If $diag = 'N'$, then $sub(A)$ is not a unit triangular matrix.

If $diag = 'U'$, then $sub(A)$ is unit triangular.

n (global) The order of the distributed matrix $sub(A)$ ($n \geq 0$).

nrhs (global) The number of right-hand sides; i.e., the number of columns of the distributed matrix $sub(B)$ ($nrhs \geq 0$).

a, b (local)

Pointers into the local memory to arrays of local sizes $lld\_a * LOCc(ja+n-1)$ and $lld\_b * LOCc(jb+nrhs-1)$, respectively.

The array *a* contains the local pieces of the distributed triangular matrix $sub(A)$.

If $uplo = 'U'$, the leading n -by- n upper triangular part of $sub(A)$ contains the upper triangular matrix, and the strictly lower triangular part of $sub(A)$ is not referenced.

If $uplo = 'L'$, the leading n -by- n lower triangular part of $sub(A)$ contains the lower triangular matrix, and the strictly upper triangular part of $sub(A)$ is not referenced.

If $diag = 'U'$, the diagonal elements of $sub(A)$ are also not referenced and are assumed to be 1.

On entry, the array *b* contains the local pieces of the right hand side distributed matrix $sub(B)$.

ia, ja (global) The row and column indices in the global matrix *A* indicating the first row and the first column of the matrix $sub(A)$, respectively.

desca (global and local) array of size $dlen\_$. The array descriptor for the distributed matrix *A*.

ib, jb (global) The row and column indices in the global matrix *B* indicating the first row and the first column of the matrix $sub(B)$, respectively.

descb (global and local) array of size $dlen\_$. The array descriptor for the distributed matrix *B*.

Output Parameters

b On exit, if $info=0$, $sub(B)$ is overwritten by the solution matrix *X*.

info If $info=0$, the execution is successful.

$info < 0$:

if the *i*-th argument is an array and the *j*-th entry, indexed *j* - 1, had an illegal value, then $info = -(i*100+j)$; if the *i*-th argument is a scalar and had an illegal value, then $info = -i$.

`info > 0:`

if `info = i`, the i -th diagonal element of $\text{sub}(A)$ is zero, indicating that the submatrix is singular and the solutions X have not been computed.

Routines for Estimating the Condition Number

This section describes the ScaLAPACK routines for estimating the condition number of a matrix. The condition number is used for analyzing the errors in the solution of a system of linear equations. Since the condition number may be arbitrarily large when the matrix is nearly singular, the routines actually compute the *reciprocal* condition number.

p?gecon

Estimates the reciprocal of the condition number of a general distributed matrix in either the 1-norm or the infinity-norm.

Syntax

```
void psgecon (char *norm , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , float *anorm , float *rcond , float *work , MKL_INT *lwork , MKL_INT *iwork ,
MKL_INT *liwork , MKL_INT *info );
```

```
void pdgecon (char *norm , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *anorm , double *rcond , double *work , MKL_INT *lwork ,
MKL_INT *iwork , MKL_INT *liwork , MKL_INT *info );
```

```
void pcgecon (char *norm , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , float *anorm , float *rcond , MKL_Complex8 *work , MKL_INT *lwork ,
float *rwork , MKL_INT *lrwork , MKL_INT *info );
```

```
void pzgecon (char *norm , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *anorm , double *rcond , MKL_Complex16 *work , MKL_INT
*lwork , double *rwork , MKL_INT *lrwork , MKL_INT *info );
```

Include Files

- `mkl_scalapack.h`

Description

The `p?gecon` function estimates the reciprocal of the condition number of a general distributed real/complex matrix $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$ in either the 1-norm or infinity-norm, using the LU factorization computed by `p?getrf`.

An estimate is obtained for $\|(\text{sub}(A))^{-1}\|$, and the reciprocal of the condition number is computed as

```
.....!..... !.....! .....
```

Input Parameters

<i>norm</i>	(global) Must be '1' or 'O' or 'I'. Specifies whether the 1-norm condition number or the infinity-norm condition number is required. If <i>norm</i> = '1' or 'O', then the 1-norm is used; If <i>norm</i> = 'I', then the infinity-norm is used.
<i>n</i>	(global) The order of the distributed matrix sub(<i>A</i>) ($n \geq 0$).
<i>a</i>	(local) Pointer into the local memory to an array of size $lld\_a * LOCC(ja+n-1)$. The array <i>a</i> contains the local pieces of the factors <i>L</i> and <i>U</i> from the factorization $sub(A) = P * L * U$; the unit diagonal elements of <i>L</i> are not stored.
<i>ia, ja</i>	(global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the matrix sub(<i>A</i>), respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .
<i>anorm</i>	(global) If <i>norm</i> = '1' or 'O', the 1-norm of the original distributed matrix sub(<i>A</i>); If <i>norm</i> = 'I', the infinity-norm of the original distributed matrix sub(<i>A</i>).
<i>work</i>	(local) The array <i>work</i> of size <i>lwork</i> is a workspace array.
<i>lwork</i>	(local or global) The size of the array <i>work</i>. For real flavors: <i>lwork</i> must be at least $lwork \geq 2 * LOCr(n + \text{mod}(ia-1, mb\_a)) + 2 * LOCC(n + \text{mod}(ja-1, nb\_a)) + \max(2, \max(nb\_a * \max(1, \text{iceil}(NPROW-1, NPCOL)), LOCC(n + \text{mod}(ja-1, nb\_a)) + nb\_a * \max(1, \text{iceil}(NPCOL-1, NPROW))))).$ For complex flavors: <i>lwork</i> must be at least $lwork \geq 2 * LOCr(n + \text{mod}(ia-1, mb\_a)) + \max(2, \max(nb\_a * \text{iceil}(NPROW-1, NPCOL), LOCC(n + \text{mod}(ja-1, nb\_a)) + nb\_a * \text{iceil}(NPCOL-1, NPROW))).$ <i>LOCr</i> and <i>LOCC</i> values can be computed using the ScaLAPACK tool function <code>numroc</code>; <i>NPROW</i> and <i>NPCOL</i> can be determined by calling the function <code>blacs_gridinfo</code>.

NOTE

$\text{iceil}(x, y)$ is the ceiling of x/y , and $\text{mod}(x, y)$ is the integer remainder of x/y .

<i>iwork</i>	(local) Workspace array of size <i>liwork</i> . Used in real flavors only.
<i>liwork</i>	(local or global) The size of the array <i>iwork</i> ; used in real flavors only. Must be at least $liwork \geq LOCr(n + \text{mod}(ia - 1, mb\_a)).$
<i>rwork</i>	(local) Workspace array of size <i>lrwork</i> . Used in complex flavors only.
<i>lrwork</i>	(local or global) The size of the array <i>rwork</i> ; used in complex flavors only. Must be at least $lrwork \geq \max(1, 2 * LOCc(n + \text{mod}(ja - 1, nb\_a))).$

Output Parameters

<i>rcond</i>	(global) The reciprocal of the condition number of the distributed matrix sub(A). See Description.
<i>work</i> [0]	On exit, <i>work</i> [0] contains the minimum value of <i>lwork</i> required for optimum performance.
<i>iwork</i> [0]	On exit, <i>iwork</i> [0] contains the minimum value of <i>liwork</i> required for optimum performance (for real flavors).
<i>rwork</i> [0]	On exit, <i>rwork</i> [0] contains the minimum value of <i>lrwork</i> required for optimum performance (for complex flavors).
<i>info</i>	(global) If <i>info</i> =0, the execution is successful. <i>info</i> < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j</i> - 1, had an illegal value, then <i>info</i> = -(<i>i</i> *100+ <i>j</i>); if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

Description

The `p?pococon` function estimates the reciprocal of the condition number (in the 1 - norm) of a real symmetric or complex Hermitian positive definite distributed matrix $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$, using the Cholesky factorization $\text{sub}(A) = U^H * U$ or $\text{sub}(A) = L * L^H$ computed by `p?potrf`.

An estimate is obtained for $\|(\text{sub}(A))^{-1}\|$, and the reciprocal of the condition number is computed as

.....! : : : : : ! : : : : : ! : : : : : !

Input Parameters

<i>uplo</i>	(global) Must be 'U' or 'L'. Specifies whether the factor stored in $\text{sub}(A)$ is upper or lower triangular. If <i>uplo</i> = 'U', $\text{sub}(A)$ stores the upper triangular factor U of the Cholesky factorization $\text{sub}(A) = U^H * U$. If <i>uplo</i> = 'L', $\text{sub}(A)$ stores the lower triangular factor L of the Cholesky factorization $\text{sub}(A) = L * L^H$.
<i>n</i>	(global) The order of the distributed matrix $\text{sub}(A)$ ($n \geq 0$).
<i>a</i>	(local) Pointer into the local memory to an array of size $\text{lld\_a} * \text{LOCc}(\text{ja}+n-1)$. The array <i>a</i> contains the local pieces of the factors L or U from the Cholesky factorization $\text{sub}(A) = U^H * U$, or $\text{sub}(A) = L * L^H$, as computed by <code>p?potrf</code> .
<i>ia, ja</i>	(global) The row and column indices in the global matrix A indicating the first row and the first column of the matrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix A .
<i>anorm</i>	(global) The 1-norm of the symmetric/Hermitian distributed matrix $\text{sub}(A)$.

<i>work</i>	(local) The array <i>work</i> of size <i>lwork</i> is a workspace array.
<i>lwork</i>	(local or global) The size of the array <i>work</i> . <i>For real flavors:</i> <i>lwork</i> must be at least $lwork \geq 2*LOCr(n+mod(ia-1,mb\_a))+2*LOCc(n+mod(ja-1,nb\_a))+max(2, max(nb\_a*iceil(NPROW-1, NPCOL), LOCc(n+mod(ja-1,nb\_a))+nb\_a*iceil(NPCOL-1, NPROW)))$ <i>For complex flavors:</i> <i>lwork</i> must be at least $lwork \geq 2*LOCr(n+mod(ia-1,mb\_a))+max(2, max(nb\_a*max(1,iceil(NPROW-1, NPCOL)), LOCc(n+mod(ja-1,nb\_a))+nb\_a*max(1,iceil(NPCOL-1, NPROW))))$
NOTE iceil(<i>x</i>,<i>y</i>) is the ceiling of <i>x</i>/<i>y</i>, and mod(<i>x</i>,<i>y</i>) is the integer remainder of <i>x</i>/<i>y</i>.	
<i>iwork</i>	(local) Workspace array of size <i>liwork</i> . Used in real flavors only.
<i>liwork</i>	(local or global) The size of the array <i>iwork</i> ; used in real flavors only. Must be at least $liwork \geq LOCr(n+mod(ia-1,mb\_a))$.
<i>rwork</i>	(local) Workspace array of size <i>lrwork</i> . Used in complex flavors only.
<i>lrwork</i>	(local or global) The size of the array <i>rwork</i> ; used in complex flavors only. Must be at least $lrwork \geq 2*LOCc(n+mod(ja-1,nb\_a))$.

Output Parameters

<i>rcond</i>	(global) The reciprocal of the condition number of the distributed matrix sub(A).
<i>work</i> [0]	On exit, <i>work</i> [0] contains the minimum value of <i>lwork</i> required for optimum performance.
<i>iwork</i> [0]	On exit, <i>iwork</i> [0] contains the minimum value of <i>liwork</i> required for optimum performance (for real flavors).
<i>rwork</i> [0]	On exit, <i>rwork</i> [0] contains the minimum value of <i>lrwork</i> required for optimum performance (for complex flavors).
<i>info</i>	(global) If <i>info</i> =0, the execution is successful. <i>info</i> < 0:

If the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

Description

The `p?trcon` function estimates the reciprocal of the condition number of a triangular distributed matrix $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$, in either the 1-norm or the infinity-norm.

The norm of $\text{sub}(A)$ is computed and an estimate is obtained for $\|(\text{sub}(A))^{-1}\|$, then the reciprocal of the condition number is computed as

.....!:::!! !:~::~:~!! !:~::~:~!!

Input Parameters

norm

(global) Must be '1' or 'O' or 'I'.

Specifies whether the 1-norm condition number or the infinity-norm condition number is required.

If *norm* = '1' or 'O', then the 1-norm is used;

If *norm* = 'I', then the infinity-norm is used.

<i>uplo</i>	(global) Must be 'U' or 'L'. If <i>uplo</i> = 'U', sub(A) is upper triangular. If <i>uplo</i> = 'L', sub(A) is lower triangular.
<i>diag</i>	(global) Must be 'N' or 'U'. If <i>diag</i> = 'N', sub(A) is non-unit triangular. If <i>diag</i> = 'U', sub(A) is unit triangular.
<i>n</i>	(global) The order of the distributed matrix sub(A), ($n \geq 0$).
<i>a</i>	(local) Pointer into the local memory to an array of size <code>lld_a*LOCc(ja+n-1)</code>. The array <i>a</i> contains the local pieces of the triangular distributed matrix sub(A). If <i>uplo</i> = 'U', the leading <i>n</i>-by-<i>n</i> upper triangular part of this distributed matrix contains the upper triangular matrix, and its strictly lower triangular part is not referenced. If <i>uplo</i> = 'L', the leading <i>n</i>-by-<i>n</i> lower triangular part of this distributed matrix contains the lower triangular matrix, and its strictly upper triangular part is not referenced. If <i>diag</i> = 'U', the diagonal elements of sub(A) are also not referenced and are assumed to be 1.
<i>ia, ja</i>	(global) The row and column indices in the global matrix A indicating the first row and the first column of the matrix sub(A), respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix A.
<i>work</i>	(local) The array <i>work</i> of size <i>lwork</i> is a workspace array.
<i>lwork</i>	(local or global) The size of the array <i>work</i>. For real flavors: <i>lwork</i> must be at least $lwork \geq 2*LOCr(n+\text{mod}(ia-1, mb\_a))+LOCc(n+\text{mod}(ja-1, nb\_a))+\max(2, \max(nb\_a*\max(1, \text{ceil}(\text{NPROW}-1, NPCOL)), LOCc(n+\text{mod}(ja-1, nb\_a))+nb\_a*\max(1, \text{ceil}(NPCOL-1, NPROW)))).$ For complex flavors: <i>lwork</i> must be at least $lwork \geq 2*LOCr(n+\text{mod}(ia-1, mb\_a))+\max(2, \max(nb\_a*\text{ceil}(\text{NPROW}-1, NPCOL), LOCc(n+\text{mod}(ja-1, nb\_a))+nb\_a*\text{ceil}(NPCOL-1, NPROW))).$

NOTE

$\text{iceil}(x, y)$ is the ceiling of x/y , and $\text{mod}(x, y)$ is the integer remainder of x/y .

<i>iwork</i>	(local) Workspace array of size <i>liwork</i> . Used in real flavors only.
<i>liwork</i>	(local or global) The size of the array <i>iwork</i> ; used in real flavors only. Must be at least $liwork \geq LOCr(n + \text{mod}(ia-1, mb\_a)).$
<i>rwork</i>	(local) Workspace array of size <i>lrwork</i> . Used in complex flavors only.
<i>lrwork</i>	(local or global) The size of the array <i>rwork</i> ; used in complex flavors only. Must be at least $lrwork \geq LOCc(n + \text{mod}(ja-1, nb\_a)).$

Output Parameters

<i>rcond</i>	(global) The reciprocal of the condition number of the distributed matrix sub(A).
<i>work</i> [0]	On exit, <i>work</i> [0] contains the minimum value of <i>lwork</i> required for optimum performance.
<i>iwork</i> [0]	On exit, <i>iwork</i> [0] contains the minimum value of <i>liwork</i> required for optimum performance (for real flavors).
<i>rwork</i> [0]	On exit, <i>rwork</i> [0] contains the minimum value of <i>lrwork</i> required for optimum performance (for complex flavors).
<i>info</i>	(global) If <i>info</i> =0, the execution is successful. $info < 0:$ If the <i>i</i>-th argument is an array and the <i>j</i>-th entry, indexed <i>j</i> - 1, had an illegal value, then <i>info</i> = -(<i>i</i>*100+<i>j</i>); if the <i>i</i>-th argument is a scalar and had an illegal value, then <i>info</i> = -<i>i</i>.

Refining the Solution and Estimating Its Error

This section describes the ScaLAPACK routines for refining the computed solution of a system of linear equations and estimating the solution error. You can call these routines after factorizing the matrix of the system of equations and computing the solution (see [Routines for Matrix Factorization](#) and [Solving Systems of Linear Equations](#)).

p?gerfs

Improves the computed solution to a system of linear equations and provides error bounds and backward error estimates for the solution.

Syntax

```
void psgerfs (char *trans , MKL_INT *n , MKL_INT *nrhs , float *a , MKL_INT *ia ,

Description

The p?gerfs function improves the computed solution to one of the systems of linear equations

$\text{sub}(A) * \text{sub}(X) = \text{sub}(B)$,

$\text{sub}(A)^T * \text{sub}(X) = \text{sub}(B)$, or

$\text{sub}(A)^H * \text{sub}(X) = \text{sub}(B)$ and provides error bounds and backward error estimates for the solution.

Here $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$, $\text{sub}(B) = B(\text{ib}:\text{ib}+n-1, \text{jb}:\text{jb}+\text{nrhs}-1)$, and $\text{sub}(X) = X(\text{ix}:\text{ix}+n-1, \text{jx}:\text{jx}+\text{nrhs}-1)$.

Input Parameters

<i>trans</i>	(global) Must be 'N' or 'T' or 'C'. Specifies the form of the system of equations: If <i>trans</i> = 'N', the system has the form $\text{sub}(A) * \text{sub}(X) = \text{sub}(B)$ (No transpose); If <i>trans</i> = 'T', the system has the form $\text{sub}(A)^T * \text{sub}(X) = \text{sub}(B)$ (Transpose);

If $trans = 'C'$, the system has the form $sub(A)^H * sub(X) = sub(B)$ (Conjugate transpose).

n	(global) The order of the distributed matrix $sub(A)$ ($n \geq 0$).
$nrhs$	(global) The number of right-hand sides, i.e., the number of columns of the matrices $sub(B)$ and $sub(X)$ ($nrhs \geq 0$).
a, af, b, x	(local) Pointers into the local memory to arrays of local sizes $a: lld\_a * LOCC(ja+n-1),$ $af: lld\_af * LOCC(jaf+n-1),$ $b: lld\_b * LOCC(jb+nrhs-1),$ $x: lld\_x * LOCC(jx+nrhs-1).$ The array a contains the local pieces of the distributed matrix $sub(A)$. The array af contains the local pieces of the distributed factors of the matrix $sub(A) = P * L * U$ as computed by <code>p?getrf</code>. The array b contains the local pieces of the distributed matrix of right hand sides $sub(B)$. On entry, the array x contains the local pieces of the distributed solution matrix $sub(X)$.
ia, ja	(global) The row and column indices in the global matrix A indicating the first row and the first column of the matrix $sub(A)$, respectively.
$desca$	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix A .
iaf, jaf	(global) The row and column indices in the global matrix AF indicating the first row and the first column of the matrix $sub(AF)$, respectively.
$descaf$	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix AF .
ib, jb	(global) The row and column indices in the global matrix B indicating the first row and the first column of the matrix $sub(B)$, respectively.
$descb$	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix B .
ix, jx	(global) The row and column indices in the global matrix X indicating the first row and the first column of the matrix $sub(X)$, respectively.
$descx$	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix X .
$ipiv$	(local) Array of size $LOCr(m\_af) + mb\_af$. This array contains pivoting information as computed by <code>p?getrf</code>. If $ipiv[i]=j$, then the local row $i+1$ was swapped with the global row j where $i=0, \dots, LOCr(m\_af) + mb\_af - 1$.

	This array is tied to the distributed matrix <i>A</i> .
<i>work</i>	(local) The array <i>work</i> of size <i>lwork</i> is a workspace array.
<i>lwork</i>	(local or global) The size of the array <i>work</i> . <i>For real flavors:</i> <i>lwork</i> must be at least $lwork \geq 3 * LOCr(n + \text{mod}(ia-1, mb\_a))$ <i>For complex flavors:</i> <i>lwork</i> must be at least $lwork \geq 2 * LOCr(n + \text{mod}(ia-1, mb\_a))$
NOTE $\text{mod}(x, y)$ is the integer remainder of x/y .	
<i>iwork</i>	(local) Workspace array, size <i>liwork</i> . Used in real flavors only.
<i>liwork</i>	(local or global) The size of the array <i>iwork</i> ; used in real flavors only. Must be at least $liwork \geq LOCr(n + \text{mod}(ib-1, mb\_b))$.
<i>rwork</i>	(local) Workspace array, size <i>lrwork</i> . Used in complex flavors only.
<i>lrwork</i>	(local or global) The size of the array <i>rwork</i> ; used in complex flavors only. Must be at least $lrwork \geq LOCr(n + \text{mod}(ib-1, mb\_b))$.

Output Parameters

<i>x</i>	On exit, contains the improved solution vectors.
<i>ferr</i> , <i>berr</i>	Arrays of size $LOCc(jb + nrhs - 1)$ each. The array <i>ferr</i> contains the estimated forward error bound for each solution vector of sub(<i>X</i>). If <i>XTRUE</i> is the true solution corresponding to sub(<i>X</i>), <i>ferr</i> is an estimated upper bound for the magnitude of the largest element in (sub(<i>X</i>) - <i>XTRUE</i>) divided by the magnitude of the largest element in sub(<i>X</i>). The estimate is as reliable as the estimate for <i>rcond</i>, and is almost always a slight overestimate of the true error. This array is tied to the distributed matrix <i>X</i>. The array <i>berr</i> contains the component-wise relative backward error of each solution vector (that is, the smallest relative change in any entry of sub(<i>A</i>) or sub(<i>B</i>) that makes sub(<i>X</i>) an exact solution). This array is tied to the distributed matrix <i>X</i>.

<code>work[0]</code>	On exit, <code>work[0]</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>iwork[0]</code>	On exit, <code>iwork[0]</code> contains the minimum value of <code>liwork</code> required for optimum performance (for real flavors).
<code>rwork[0]</code>	On exit, <code>rwork[0]</code> contains the minimum value of <code>lrwork</code> required for optimum performance (for complex flavors).
<code>info</code>	(global) If <code>info=0</code> , the execution is successful. <code>info < 0</code> : If the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then <code>info = -(i*100+j)</code> ; if the i -th argument is a scalar and had an illegal value, then <code>info = -i</code> .

Description

The `p?porfs` function improves the computed solution to the system of linear equations

$$\text{sub}(A) * \text{sub}(X) = \text{sub}(B),$$

where $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$ is a real symmetric or complex Hermitian positive definite distributed matrix and

$$\text{sub}(B) = B(\text{ib}:\text{ib}+n-1, \text{jb}:\text{jb}+nrhs-1),$$

$$\text{sub}(X) = X(\text{ix}:\text{ix}+n-1, \text{jx}:\text{jx}+nrhs-1)$$

are right-hand side and solution submatrices, respectively. This function also provides error bounds and backward error estimates for the solution.

Input Parameters

<i>uplo</i>	(global) Must be 'U' or 'L'. Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix $\text{sub}(A)$ is stored. If <i>uplo</i> = 'U', $\text{sub}(A)$ is upper triangular. If <i>uplo</i> = 'L', $\text{sub}(A)$ is lower triangular.
<i>n</i>	(global) The order of the distributed matrix $\text{sub}(A)$ ($n \geq 0$).
<i>nrhs</i>	(global) The number of right-hand sides, i.e., the number of columns of the matrices $\text{sub}(B)$ and $\text{sub}(X)$ ($nrhs \geq 0$).
<i>a, af, b, x</i>	(local) Pointers into the local memory to arrays of local sizes <i>a</i>: $\text{lld\_a} * \text{LOCc}(\text{ja}+n-1)$, <i>af</i>: $\text{lld\_af} * \text{LOCc}(\text{jaf}+n-1)$, <i>b</i>: $\text{lld\_b} * \text{LOCc}(\text{jb}+nrhs-1)$, <i>x</i>: $\text{lld\_x} * \text{LOCc}(\text{jx}+nrhs-1)$. The array <i>a</i> contains the local pieces of the <i>n</i>-by-<i>n</i> symmetric/Hermitian distributed matrix $\text{sub}(A)$. If <i>uplo</i> = 'U', the leading <i>n</i>-by-<i>n</i> upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced. If <i>uplo</i> = 'L', the leading <i>n</i>-by-<i>n</i> lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the distributed matrix, and its strictly upper triangular part is not referenced. The array <i>af</i> contains the factors <i>L</i> or <i>U</i> from the Cholesky factorization $\text{sub}(A) = L * L^H$ or $\text{sub}(A) = U^H * U$, as computed by <code>p?potrf</code>. On entry, the array <i>b</i> contains the local pieces of the distributed matrix of right hand sides $\text{sub}(B)$. On entry, the array <i>x</i> contains the local pieces of the solution vectors $\text{sub}(X)$.
<i>ia, ja</i>	(global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the matrix $\text{sub}(A)$, respectively.

<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .
<i>iaf, jaf</i>	(global) The row and column indices in the global matrix <i>AF</i> indicating the first row and the first column of the matrix sub(<i>AF</i>), respectively.
<i>descaf</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>AF</i> .
<i>ib, jb</i>	(global) The row and column indices in the global matrix <i>B</i> indicating the first row and the first column of the matrix sub(<i>B</i>), respectively.
<i>descb</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>B</i> .
<i>ix, jx</i>	(global) The row and column indices in the global matrix <i>X</i> indicating the first row and the first column of the matrix sub(<i>X</i>), respectively.
<i>descx</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>X</i> .
<i>work</i>	(local) The array <i>work</i> of size <i>lwork</i> is a workspace array.
<i>lwork</i>	(local) The size of the array <i>work</i> . <i>For real flavors:</i> <i>lwork</i> must be at least $lwork \geq 3 * LOCr(n + \text{mod}(ia-1, mb\_a))$ <i>For complex flavors:</i> <i>lwork</i> must be at least $lwork \geq 2 * LOCr(n + \text{mod}(ia-1, mb\_a))$
NOTE mod(<i>x</i>, <i>y</i>) is the integer remainder of <i>x</i>/<i>y</i>.	
<i>iwork</i>	(local) Workspace array of size <i>liwork</i> . Used in real flavors only.
<i>liwork</i>	(local or global) The size of the array <i>iwork</i> ; used in real flavors only. Must be at least $liwork \geq LOCr(n + \text{mod}(ib-1, mb\_b))$.
<i>rwork</i>	(local) Workspace array of size <i>lrwork</i> . Used in complex flavors only.
<i>lrwork</i>	(local or global) The size of the array <i>rwork</i> ; used in complex flavors only. Must be at least $lrwork \geq LOCr(n + \text{mod}(ib-1, mb\_b))$.

Output Parameters

<i>x</i>	On exit, contains the improved solution vectors.

<i>ferr</i> , <i>berr</i>	Arrays of size $LOC(jb+nrhs-1)$ each. The array <i>ferr</i> contains the estimated forward error bound for each solution vector of sub(X). If XTRUE is the true solution corresponding to sub(X), <i>ferr</i> is an estimated upper bound for the magnitude of the largest element in (sub(X) - XTRUE) divided by the magnitude of the largest element in sub(X). The estimate is as reliable as the estimate for <i>rcond</i>, and is almost always a slight overestimate of the true error. This array is tied to the distributed matrix X. The array <i>berr</i> contains the component-wise relative backward error of each solution vector (that is, the smallest relative change in any entry of sub(A) or sub(B) that makes sub(X) an exact solution). This array is tied to the distributed matrix X.
<i>work</i> [0]	On exit, <i>work</i> [0] contains the minimum value of <i>lwork</i> required for optimum performance.
<i>iwork</i> [0]	On exit, <i>iwork</i> [0] contains the minimum value of <i>liwork</i> required for optimum performance (for real flavors).
<i>rwork</i> [0]	On exit, <i>rwork</i> [0] contains the minimum value of <i>lrwork</i> required for optimum performance (for complex flavors).
<i>info</i>	(global) If <i>info</i>=0, the execution is successful. <i>info</i> < 0: If the <i>i</i>-th argument is an array and the <i>j</i>-th entry, indexed <i>j</i> - 1, had an illegal value, then <i>info</i> = -(<i>i</i>*100+<i>j</i>); if the <i>i</i>-th argument is a scalar and had an illegal value, then <i>info</i> = -<i>i</i>.

Description

The `p?trfs` function provides error bounds and backward error estimates for the solution to one of the systems of linear equations

$$\text{sub}(A) * \text{sub}(X) = \text{sub}(B),$$

$$\text{sub}(A)^T * \text{sub}(X) = \text{sub}(B), \text{ or}$$

$$\text{sub}(A)^H * \text{sub}(X) = \text{sub}(B),$$

where $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$ is a triangular matrix,

$\text{sub}(B) = B(\text{ib}:\text{ib}+n-1, \text{jb}:\text{jb}+nrhs-1)$, and

$\text{sub}(X) = X(\text{ix}:\text{ix}+n-1, \text{jx}:\text{jx}+nrhs-1)$.

The solution matrix X must be computed by `p?trtrs` or some other means before entering this function. The function `p?trfs` does not do iterative refinement because doing so cannot improve the backward error.

Input Parameters

<i>uplo</i>	(global) Must be 'U' or 'L'. If <i>uplo</i> = 'U', $\text{sub}(A)$ is upper triangular. If <i>uplo</i> = 'L', $\text{sub}(A)$ is lower triangular.
<i>trans</i>	(global) Must be 'N' or 'T' or 'C'. Specifies the form of the system of equations: If <i>trans</i> = 'N', the system has the form $\text{sub}(A) * \text{sub}(X) = \text{sub}(B)$ (No transpose); If <i>trans</i> = 'T', the system has the form $\text{sub}(A)^T * \text{sub}(X) = \text{sub}(B)$ (Transpose); If <i>trans</i> = 'C', the system has the form $\text{sub}(A)^H * \text{sub}(X) = \text{sub}(B)$ (Conjugate transpose).
<i>diag</i>	Must be 'N' or 'U'. If <i>diag</i> = 'N', then $\text{sub}(A)$ is non-unit triangular. If <i>diag</i> = 'U', then $\text{sub}(A)$ is unit triangular.
<i>n</i>	(global) The order of the distributed matrix $\text{sub}(A)$ ($n \geq 0$).

<i>nrhs</i>	(global) The number of right-hand sides, that is, the number of columns of the matrices $\text{sub}(B)$ and $\text{sub}(X)$ ($nrhs \geq 0$).
<i>a, b, x</i>	(local) Pointers into the local memory to arrays of local sizes <i>a</i>: $lld\_a * LOCc(ja+n-1)$, <i>b</i>: $lld\_b * LOCc(jb+nrhs-1)$, <i>x</i>: $lld\_x * LOCc(jx+nrhs-1)$. The array <i>a</i> contains the local pieces of the original triangular distributed matrix $\text{sub}(A)$. If <i>uplo</i> = 'U', the leading <i>n</i>-by-<i>n</i> upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced. If <i>uplo</i> = 'L', the leading <i>n</i>-by-<i>n</i> lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the distributed matrix, and its strictly upper triangular part is not referenced. If <i>diag</i> = 'U', the diagonal elements of $\text{sub}(A)$ are also not referenced and are assumed to be 1. On entry, the array <i>b</i> contains the local pieces of the distributed matrix of right hand sides $\text{sub}(B)$. On entry, the array <i>x</i> contains the local pieces of the solution vectors $\text{sub}(X)$.
<i>ia, ja</i>	(global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the matrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .
<i>ib, jb</i>	(global) The row and column indices in the global matrix <i>B</i> indicating the first row and the first column of the matrix $\text{sub}(B)$, respectively.
<i>descb</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>B</i> .
<i>ix, jx</i>	(global) The row and column indices in the global matrix <i>X</i> indicating the first row and the first column of the matrix $\text{sub}(X)$, respectively.
<i>descx</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>X</i> .
<i>work</i>	(local) The array <i>work</i> of size <i>lwork</i> is a workspace array.
<i>lwork</i>	(local) The size of the array <i>work</i>. For real flavors: <i>lwork</i> must be at least $lwork \geq 3 * LOCr(n + \text{mod}(ia-1, mb\_a))$ For complex flavors: <i>lwork</i> must be at least

$$lwork \geq 2 * LOCr(n + \text{mod}(ia-1, mb\_a))$$
NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

<i>iwork</i>	(local) Workspace array of size <i>liwork</i> . Used in real flavors only.
<i>liwork</i>	(local or global) The size of the array <i>iwork</i> ; used in real flavors only. Must be at least $liwork \geq LOCr(n + \text{mod}(ib-1, mb\_b)).$
<i>rwork</i>	(local) Workspace array of size <i>lrwork</i> . Used in complex flavors only.
<i>lrwork</i>	(local or global) The size of the array <i>rwork</i> ; used in complex flavors only. Must be at least $lrwork \geq LOCr(n + \text{mod}(ib-1, mb\_b))$.

Output Parameters

<i>ferr, berr</i>	Arrays of size $LOCc(jb + nrhs - 1)$ each. The array <i>ferr</i> contains the estimated forward error bound for each solution vector of sub(X). If XTRUE is the true solution corresponding to sub(X), <i>ferr</i> is an estimated upper bound for the magnitude of the largest element in $(\text{sub}(X) - XTRUE)$ divided by the magnitude of the largest element in sub(X). The estimate is as reliable as the estimate for <i>rcond</i>, and is almost always a slight overestimate of the true error. This array is tied to the distributed matrix X. The array <i>berr</i> contains the component-wise relative backward error of each solution vector (that is, the smallest relative change in any entry of sub(A) or sub(B) that makes sub(X) an exact solution). This array is tied to the distributed matrix X.
<i>work</i> [0]	On exit, <i>work</i> [0] contains the minimum value of <i>lwork</i> required for optimum performance.
<i>iwork</i> [0]	On exit, <i>iwork</i> [0] contains the minimum value of <i>liwork</i> required for optimum performance (for real flavors).
<i>rwork</i> [0]	On exit, <i>rwork</i> [0] contains the minimum value of <i>lrwork</i> required for optimum performance (for complex flavors).
<i>info</i>	(global) If <i>info</i>=0, the execution is successful. $info < 0$: If the <i>i</i>-th argument is an array and the <i>j</i>-th entry, indexed <i>j</i> - 1, had an illegal value, then $info = -(i*100+j)$; if the <i>i</i>-th argument is a scalar and had an illegal value, then $info = -i$.

Routines for Matrix Inversion

This sections describes ScaLAPACK routines that compute the inverse of a matrix based on the previously obtained factorization. Note that it is not recommended to solve a system of equations $Ax = b$ by first computing A^{-1} and then forming the matrix-vector product $x = A^{-1}b$. Call a solver routine instead (see [Solving Systems of Linear Equations](#)); this is more efficient and more accurate.

p?getri

Computes the inverse of a LU-factored distributed matrix.

Syntax

```
void psgetri (MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca ,
MKL_INT *ipiv , float *work , MKL_INT *lwork , MKL_INT *iwork , MKL_INT *liwork ,
MKL_INT *info );

void pdgetri (MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca ,
MKL_INT *ipiv , double *work , MKL_INT *lwork , MKL_INT *iwork , MKL_INT *liwork ,
MKL_INT *info );

void pcgetri (MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , MKL_INT *ipiv , MKL_Complex8 *work , MKL_INT *lwork , MKL_INT *iwork ,
MKL_INT *liwork , MKL_INT *info );

void pzgetri (MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , MKL_INT *ipiv , MKL_Complex16 *work , MKL_INT *lwork , MKL_INT *iwork ,
MKL_INT *liwork , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The p?getri function computes the inverse of a general distributed matrix $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$ using the LU factorization computed by p?getrf. This method inverts U and then computes the inverse of $\text{sub}(A)$ by solving the system

$$\text{inv}(\text{sub}(A)) * L = \text{inv}(U)$$

for $\text{inv}(\text{sub}(A))$.

Input Parameters

<i>n</i>	(global) The number of rows and columns to be operated on, that is, the order of the distributed matrix $\text{sub}(A)$ ($n \geq 0$).
<i>a</i>	(local) Pointer into the local memory to an array of local size $lld\_a * LOCC(ja+n-1)$. On entry, the array <i>a</i> contains the local pieces of the L and U obtained by the factorization $\text{sub}(A) = P * L * U$ computed by p?getrf.
<i>ia, ja</i>	(global) The row and column indices in the global matrix A indicating the first row and the first column of the matrix $\text{sub}(A)$, respectively.

desca (global and local) array of size *dlen_*. The array descriptor for the distributed matrix *A*.

work (local)
The array *work* of size *lwork* is a workspace array.

lwork (local) The size of the array *work*. *lwork* must be at least
 $lwork \geq LOCr(n + \text{mod}(ia-1, mb\_a)) * nb\_a$.

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

The array *work* is used to keep at most an entire column block of sub(*A*).

iwork (local) Workspace array used for physically transposing the pivots, size *liwork*.

liwork (local or global) The size of the array *iwork*.

The minimal value *liwork* of is determined by the following code:

```
if NPROW == NPCOL then
  liwork = LOCc(n_a + mod(ja-1, nb_a)) + nb_a
else
  liwork = LOCc(n_a + mod(ja-1, nb_a)) +
    max(ceil(ceil(LOCr(m_a)/mb_a)/(lcm/NPROW)), nb_a)
end if
```

where *lcm* is the least common multiple of process rows and columns (NPROW and NPCOL).

Output Parameters

ipiv (local)
Array of size $LOCr(m\_a) + mb\_a$.
This array contains the pivoting information.
If *ipiv*[*i*]=*j*, then the local row *i*+1 was swapped with the global row *j* where *i*=0, ..., $LOCr(m\_a) + mb\_a - 1$.
This array is tied to the distributed matrix *A*.

work[0] On exit, *work*[0] contains the minimum value of *lwork* required for optimum performance.

iwork[0] On exit, *iwork*[0] contains the minimum value of *liwork* required for optimum performance.

info (global) If *info*=0, the execution is successful.
info < 0:

If the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

$info > 0$:

If $info = i$, the matrix element $U(i,i)$ is exactly zero. The factorization has been completed, but the factor U is exactly singular, and division by zero will occur if it is used to solve a system of equations.

p?potri

Computes the inverse of a symmetric/Hermitian positive definite distributed matrix.

Syntax

```
void pspotri (char *uplo , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
```

```
void pdpotri (char *uplo , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
```

```
void pcpotri (char *uplo , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
```

```
void pzpotri (char *uplo , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The `p?potri` function computes the inverse of a real symmetric or complex Hermitian positive definite distributed matrix $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$ using the Cholesky factorization $\text{sub}(A) = U^H * U$ or $\text{sub}(A) = L * L^H$ computed by `p?potrf`.

Input Parameters

<code>uplo</code>	(global) Must be 'U' or 'L'. Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix $\text{sub}(A)$ is stored. If <code>uplo = 'U'</code> , upper triangle of $\text{sub}(A)$ is stored. If <code>uplo = 'L'</code> , lower triangle of $\text{sub}(A)$ is stored.
<code>n</code>	(global) The number of rows and columns to be operated on, that is, the order of the distributed matrix $\text{sub}(A)$ ($n \geq 0$).
<code>a</code>	(local) Pointer into the local memory to an array of local size <code>lld_a * LOCC(ja+n-1)</code> .

On entry, the array *a* contains the local pieces of the triangular factor *U* or *L* from the Cholesky factorization $\text{sub}(A) = U^H * U$, or $\text{sub}(A) = L * L^H$, as computed by `p?potrf`.

ia, ja (global) The row and column indices in the global matrix *A* indicating the first row and the first column of the matrix $\text{sub}(A)$, respectively.

desca (global and local) array of size *dlen_*. The array descriptor for the distributed matrix *A*.

Output Parameters

a On exit, overwritten by the local pieces of the upper or lower triangle of the (symmetric/Hermitian) inverse of $\text{sub}(A)$.

info (global) If *info*=0, the execution is successful.

info < 0:

If the *i*-th argument is an array and the *j*-th entry, indexed *j* - 1, had an illegal value, then *info* = -(*i**100+*j*); if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

info > 0:

If *info* = *i*, the element (*i*, *i*) of the factor *U* or *L* is zero, and the inverse could not be computed.

p?trtri

Computes the inverse of a triangular distributed matrix.

Syntax

```
void pstrtri (char *uplo , char *diag , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT
             *ja , MKL_INT *desca , MKL_INT *info );

void pdtrtri (char *uplo , char *diag , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT
             *ja , MKL_INT *desca , MKL_INT *info );

void pctrtri (char *uplo , char *diag , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia ,
             MKL_INT *ja , MKL_INT *desca , MKL_INT *info );

void pztrtri (char *uplo , char *diag , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia ,
             MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
```

Include Files

- `mk1_scalapack.h`

Description

The `p?trtri` function computes the inverse of a real or complex upper or lower triangular distributed matrix $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$.

Input Parameters

<i>uplo</i>	(global) Must be 'U' or 'L'. Specifies whether the distributed matrix sub(A) is upper or lower triangular. If <i>uplo</i> = 'U', sub(A) is upper triangular. If <i>uplo</i> = 'L', sub(A) is lower triangular.
<i>diag</i>	Must be 'N' or 'U'. Specifies whether or not the distributed matrix sub(A) is unit triangular. If <i>diag</i> = 'N', then sub(A) is non-unit triangular. If <i>diag</i> = 'U', then sub(A) is unit triangular.
<i>n</i>	(global) The number of rows and columns to be operated on, that is, the order of the distributed matrix sub(A) ($n \geq 0$).
<i>a</i>	(local) Pointer into the local memory to an array of local size $ld\_a * LOCc(ja+n-1)$. The array <i>a</i> contains the local pieces of the triangular distributed matrix sub(A). If <i>uplo</i> = 'U', the leading <i>n</i>-by-<i>n</i> upper triangular part of sub(A) contains the upper triangular matrix to be inverted, and the strictly lower triangular part of sub(A) is not referenced. If <i>uplo</i> = 'L', the leading <i>n</i>-by-<i>n</i> lower triangular part of sub(A) contains the lower triangular matrix, and the strictly upper triangular part of sub(A) is not referenced.
<i>ia, ja</i>	(global) The row and column indices in the global matrix A indicating the first row and the first column of the matrix sub(A), respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i>. The array descriptor for the distributed matrix A.

Output Parameters

<i>a</i>	On exit, overwritten by the (triangular) inverse of the original matrix.
<i>info</i>	(global) If <i>info</i>=0, the execution is successful. <i>info</i> < 0: If the <i>i</i>-th argument is an array and the <i>j</i>-th entry, indexed <i>j</i> - 1, had an illegal value, then <i>info</i> = -(<i>i</i>*100+<i>j</i>); if the <i>i</i>-th argument is a scalar and had an illegal value, then <i>info</i> = -<i>i</i>. <i>info</i> > 0: If <i>info</i> = <i>k</i>, the matrix element <i>A</i>(<i>ia</i>+<i>k</i>-1, <i>ja</i>+<i>k</i>-1) is exactly zero. The triangular matrix sub(A) is singular and its inverse cannot be computed.

Routines for Matrix Equilibration

ScaLAPACK routines described in this section are used to compute scaling factors needed to equilibrate a matrix. Note that these routines do not actually scale the matrices.

p?geequ

Computes row and column scaling factors intended to equilibrate a general rectangular distributed matrix and reduce its condition number.

Syntax

```
void psgeequ (MKL_INT *m , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , float *r , float *c , float *rowcnd , float *colcnd , float *amax , MKL_INT
*info );
```

```
void pdgeequ (MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *r , double *c , double *rowcnd , double *colcnd , double
*amax , MKL_INT *info );
```

```
void pcgeequ (MKL_INT *m , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , float *r , float *c , float *rowcnd , float *colcnd , float *amax ,
MKL_INT *info );
```

```
void pzgeequ (MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *r , double *c , double *rowcnd , double *colcnd , double
*amax , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The p?geequ function computes row and column scalings intended to equilibrate an m -by- n distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$ and reduce its condition number. The output array r returns the row scale factors r_i , and the array c returns the column scale factors c_j . These factors are chosen to try to make the largest element in each row and column of the matrix B with elements $b_{ij}=r_i*a_{ij}*c_j$ have absolute value 1.

r_i and c_j are restricted to be between $SMLNUM$ = smallest safe number and $BIGNUM$ = largest safe number. Use of these scaling factors is not guaranteed to reduce the condition number of $\text{sub}(A)$ but works well in practice.

$SMLNUM$ and $BIGNUM$ are parameters representing machine precision. You can use the ?lamch routines to compute them. For example, compute single precision values of $SMLNUM$ and $BIGNUM$ as follows:

```
SMLNUM = slamch ('s')
BIGNUM = 1 / SMLNUM
```

The auxiliary function p?laqge uses scaling factors computed by p?geequ to scale a general rectangular matrix.

Input Parameters

m	(global) The number of rows to be operated on, that is, the number of rows of the distributed matrix $\text{sub}(A)$ ($m \geq 0$).
n	(global) The number of columns to be operated on, that is, the number of columns of the distributed matrix $\text{sub}(A)$ ($n \geq 0$).

<i>a</i>	(local) Pointer into the local memory to an array of local size $lld\_a * LOCC(ja+n-1)$. The array <i>a</i> contains the local pieces of the <i>m</i> -by- <i>n</i> distributed matrix whose equilibration factors are to be computed.
<i>ia, ja</i>	(global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the matrix sub(<i>A</i>), respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .

Output Parameters

<i>r, c</i>	(local) Arrays of sizes $LOCr(m\_a)$ and $LOCC(n\_a)$, respectively. If <i>info</i> = 0, or <i>info</i> > <i>ia</i> + <i>m</i> -1, <i>r</i> [<i>i</i>] contain the row scale factors for sub(<i>A</i>) for $ia-1 \leq i < ia+m-1$. <i>r</i> is aligned with the distributed matrix <i>A</i> , and replicated across every process column. <i>r</i> is tied to the distributed matrix <i>A</i> . If <i>info</i> = 0, <i>c</i> [<i>i</i>] contain the column scale factors for sub(<i>A</i>) for $ja-1 \leq i < ja+n-1$. <i>c</i> is aligned with the distributed matrix <i>A</i> , and replicated down every process row. <i>c</i> is tied to the distributed matrix <i>A</i> .
<i>rowcnd, colcnd</i>	(global) If <i>info</i> = 0 or <i>info</i> > <i>ia</i> + <i>m</i> -1, <i>rowcnd</i> contains the ratio of the smallest r_i to the largest r_i ($ia \leq i \leq ia+m-1$). If <i>rowcnd</i> ≥ 0.1 and <i>amax</i> is neither too large nor too small, it is not worth scaling by r_i . If <i>info</i> = 0, <i>colcnd</i> contains the ratio of the smallest c_j to the largest c_j ($ja \leq j \leq ja+n-1$). If <i>colcnd</i> ≥ 0.1 , it is not worth scaling by c_j .
<i>amax</i>	(global) Absolute value of the largest matrix element. If <i>amax</i> is very close to overflow or very close to underflow, the matrix should be scaled.
<i>info</i>	(global) If <i>info</i> =0, the execution is successful. <i>info</i> < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j</i> - 1, had an illegal value, then <i>info</i> = -(<i>i</i> *100+ <i>j</i>); if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> . <i>info</i> > 0: If <i>info</i> = <i>i</i> and $i \leq m$, the <i>i</i> -th row of the distributed matrix sub(<i>A</i>) is exactly zero; $i > m$, the (<i>i</i> - <i>m</i>)-th column of the distributed matrix sub(<i>A</i>) is exactly zero.

See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

p?poequ

Computes row and column scaling factors intended to equilibrate a symmetric (Hermitian) positive definite distributed matrix and reduce its condition number.

Syntax

```
void pspoequ (MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca ,
float *sr , float *sc , float *scond , float *amax , MKL_INT *info );

void pdpoequ (MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca ,
double *sr , double *sc , double *scond , double *amax , MKL_INT *info );

void pcspoequ (MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , float *sr , float *sc , float *scond , float *amax , MKL_INT *info );

void pzspoequ (MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , double *sr , double *sc , double *scond , double *amax , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The `p?poequ` function computes row and column scalings intended to equilibrate a real symmetric or complex Hermitian positive definite distributed matrix $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$ and reduce its condition number (with respect to the two-norm). The output arrays `sr` and `sc` return the row and column scale factors

, ! ! ! ! ! ! ! !

These factors are chosen so that the scaled distributed matrix B with elements $b_{ij}=s(i)*a_{ij}*s(j)$ has ones on the diagonal.

This choice of `sr` and `sc` puts the condition number of B within a factor n of the smallest possible condition number over all possible diagonal scalings.

The auxiliary function `p?laqsy` uses scaling factors computed by `p?geequ` to scale a general rectangular matrix.

Input Parameters

<code>n</code>	(global) The number of rows and columns to be operated on, that is, the order of the distributed matrix $\text{sub}(A)$ ($n \geq 0$).
<code>a</code>	(local) Pointer into the local memory to an array of local size <code>lld_a*LOCc(ja+n-1)</code>. The array <code>a</code> contains the n-by-n symmetric/Hermitian positive definite distributed matrix $\text{sub}(A)$ whose scaling factors are to be computed. Only the diagonal elements of $\text{sub}(A)$ are referenced.

<i>ia, ja</i>	(global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the matrix sub(<i>A</i>), respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .

Output Parameters

<i>sr, sc</i>	(local) Arrays of sizes <i>LOCr(m_a)</i> and <i>LOCc(n_a)</i>, respectively. If <i>info</i> = 0, the array <i>sr(ia:ia+n-1)</i> contains the row scale factors for sub(<i>A</i>). <i>sr</i> is aligned with the distributed matrix <i>A</i>, and replicated across every process column. <i>sr</i> is tied to the distributed matrix <i>A</i>. If <i>info</i> = 0, the array <i>sc(ja:ja+n-1)</i> contains the column scale factors for sub(<i>A</i>). <i>sc</i> is aligned with the distributed matrix <i>A</i>, and replicated down every process row. <i>sc</i> is tied to the distributed matrix <i>A</i>.
<i>scond</i>	(global) If <i>info</i> = 0, <i>scond</i> contains the ratio of the smallest <i>sr[j]</i> (or <i>sc[j]</i>) to the largest <i>sr[i]</i> (or <i>sc[j]</i>), with $ia-1 \leq i < ia+n-1 \text{ and } ja-1 \leq j < ja+n-1.$ If <i>scond</i> ≥ 0.1 and <i>amax</i> is neither too large nor too small, it is not worth scaling by <i>sr</i> (or <i>sc</i>).
<i>amax</i>	(global) Absolute value of the largest matrix element. If <i>amax</i> is very close to overflow or very close to underflow, the matrix should be scaled.
<i>info</i>	(global) If <i>info</i>=0, the execution is successful. <i>info</i> < 0: If the <i>i</i>-th argument is an array and the <i>j</i>-th entry, indexed <i>j</i> - 1, had an illegal value, then <i>info</i> = -(<i>i</i>*100+<i>j</i>); if the <i>i</i>-th argument is a scalar and had an illegal value, then <i>info</i> = -<i>i</i>. <i>info</i> > 0: If <i>info</i> = <i>k</i>, the <i>k</i>-th diagonal entry of sub(<i>A</i>) is nonpositive.

general matrices, QL factorization	p?geqlf		p?orgql p?ungql	p?ormql p?unmql
trapezoidal matrices, RZ factorization	p?tzzrf			p?ormrz p?unmrz
pair of matrices, generalized QR factorization	p?ggqrf			
pair of matrices, generalized RQ factorization	p?ggrqf			

[p?geqrf](#)

Computes the QR factorization of a general m -by- n matrix.

Syntax

```
void psgeqrf (MKL_INT *m , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , float *tau , float *work , MKL_INT *lwork , MKL_INT *info );

void pdgeqrf (MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *tau , double *work , MKL_INT *lwork , MKL_INT *info );

void pcgeqrf (MKL_INT *m , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_Complex8 *tau , MKL_Complex8 *work , MKL_INT *lwork , MKL_INT
*info );

void pzgeqrf (MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_Complex16 *tau , MKL_Complex16 *work , MKL_INT *lwork , MKL_INT
*info );
```

Include Files

- `mkl_scalapack.h`

Description

The `p?geqrf` function forms the QR factorization of a general m -by- n distributed matrix $\text{sub}(A) = A(ia:ia + m - 1, ja:ja + n - 1)$ as

$A = Q * R$.

Input Parameters

<i>m</i>	(global) The number of rows in the distributed matrix sub(<i>A</i>); ($m \geq 0$).
<i>n</i>	(global) The number of columns in the distributed matrix sub(<i>A</i>); ($n \geq 0$).
<i>a</i>	(local) Pointer into the local memory to an array of local size $lld\_a * LOCC(ja+n-1)$. Contains the local pieces of the distributed matrix sub(<i>A</i>) to be factored.
<i>ia, ja</i>	(global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the submatrix <i>A</i> (<i>ia:ia+m-1, ja:ja+n-1</i>), respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i>
<i>work</i>	(local). Workspace array of size <i>lwork</i> .
<i>lwork</i>	(local or global) size of <i>work</i> , must be at least $lwork \geq nb\_a * (mp0+nq0+nb\_a)$, where $iroff = \text{mod}(ia-1, mb\_a), \quad icoff = \text{mod}(ja-1, nb\_a),$ $iarow = \text{indxg2p}(ia, mb\_a, MYROW, rsrc\_a, NPROW),$ $iacol = \text{indxg2p}(ja, nb\_a, MYCOL, csrc\_a, NPCOL),$ $mp0 = \text{numroc}(m+iroff, mb\_a, MYROW, iarow, NPROW),$ $nq0 = \text{numroc}(n+icoff, nb\_a, MYCOL, iacol, NPCOL),$ and <i>numroc</i> , <i>indxg2p</i> are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the function <i>blacs_gridinfo</i> . If <i>lwork</i> = -1, then <i>lwork</i> is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by <i>pxerbla</i> .

Output Parameters

<i>a</i>	The elements on and above the diagonal of sub(<i>A</i>) contain the min(<i>m,n</i>)-by- <i>n</i> upper trapezoidal matrix <i>R</i> (<i>R</i> is upper triangular if $m \geq n$); the elements below the diagonal, with the array <i>tau</i> , represent the orthogonal/unitary matrix <i>Q</i> as a product of elementary reflectors (see <i>Application Notes</i> below).
<i>tau</i>	(local) Array of size $LOCC(ja+\min(m,n)-1)$. Contains the scalar factor of elementary reflectors. <i>tau</i> is tied to the distributed matrix <i>A</i> .
<i>work</i> [0]	On exit, <i>work</i> [0] contains the minimum value of <i>lwork</i> required for optimum performance.

info (global)
 = 0, the execution is successful.
 < 0, if the *i*-th argument is an array and the *j*-th entry, indexed *j* - 1, had an illegal value, then *info* = $-(i*100+j)$; if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

Application Notes

The matrix *Q* is represented as a product of elementary reflectors

$$Q = H(j_a) * H(j_a+1) * \dots * H(j_a+k-1),$$

where $k = \min(m, n)$.

Each *H(i)* has the form

$$H(i) = I - \tau * v * v'$$

where *tau* is a real/complex scalar, and *v* is a real/complex vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:m)$ is stored on exit in $A(ia+i:ia+m-1, ja+i-1)$, and *tau* in $\tau[ja+i-2]$.

p?geqpf

Computes the QR factorization of a general m-by-n matrix with pivoting.

Syntax

```
void psgeqpf (MKL_INT *m , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , MKL_INT *ipiv , float *tau , float *work , MKL_INT *lwork , MKL_INT *info );
```

```
void pdgeqpf (MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_INT *ipiv , double *tau , double *work , MKL_INT *lwork , MKL_INT
*info );
```

```
void pcgeqpf (MKL_INT *m , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_INT *ipiv , MKL_Complex8 *tau , MKL_Complex8 *work , MKL_INT
*lwork , float *rwork , MKL_INT *lrwork , MKL_INT *info );
```

```
void pzgeqpf (MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_INT *ipiv , MKL_Complex16 *tau , MKL_Complex16 *work , MKL_INT
*lwork , double *rwork , MKL_INT *lrwork , MKL_INT *info );
```

Include Files

- `mkl_scalapack.h`

Description

The `p?geqpf` function forms the QR factorization with column pivoting of a general *m*-by-*n* distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$ as

$$\text{sub}(A) * P = Q * R.$$

Input Parameters

m (global) The number of rows in the matrix $\text{sub}(A)$ ($m \geq 0$).

<i>n</i>	(global) The number of columns in the matrix $\text{sub}(A)$ ($n \geq 0$).
<i>a</i>	(local) Pointer into the local memory to an array of local size $lld\_a * LOCc(ja+n-1)$. Contains the local pieces of the distributed matrix $\text{sub}(A)$ to be factored.
<i>ia, ja</i>	(global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the submatrix $A(ia:ia+m-1, ja:ja+n-1)$, respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .
<i>work</i>	(local). Workspace array of size <i>lwork</i> .
<i>lwork</i>	(local or global) size of <i>work</i> , must be at least For real flavors: $lwork \geq \max(3, mp0 + nq0) + LOCc(ja+n-1) + nq0$. For complex flavors: $lwork \geq \max(3, mp0 + nq0)$. Here $iroff = \text{mod}(ia-1, mb\_a), icoff = \text{mod}(ja-1, nb\_a),$ $iarow = \text{indxg2p}(ia, mb\_a, MYROW, rsrc\_a, NPROW),$ $iacol = \text{indxg2p}(ja, nb\_a, MYCOL, csrc\_a, NPCOL),$ $mp0 = \text{numroc}(m+iroff, mb\_a, MYROW, iarow, NPROW),$ $nq0 = \text{numroc}(n+icoff, nb\_a, MYCOL, iacol, NPCOL),$ $LOCc(ja+n-1) = \text{numroc}(ja+n-1, nb\_a, MYCOL, csrc\_a, NPCOL),$ and $\text{numroc}, \text{indxg2p}$ are ScaLAPACK tool functions. You can determine MYROW, MYCOL, NPROW and NPCOL by calling the <code>blacs_gridinfo</code> function. If <i>lwork</i> = -1, then <i>lwork</i> is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla .
<i>rwork</i>	(local). Workspace array of size <i>lrwork</i> (complex flavors only).
<i>lrwork</i>	(local or global) size of <i>rwork</i> (complex flavors only). The value of <i>lrwork</i> must be at least $lwork \geq LOCc(ja+n-1) + nq0$. Here $iroff = \text{mod}(ia-1, mb\_a), icoff = \text{mod}(ja-1, nb\_a),$ $iarow = \text{indxg2p}(ia, mb\_a, MYROW, rsrc\_a, NPROW),$

```
iacol = indxg2p(ja, nb_a, MYCOL, csrc_a, NPCOL),
mp0 = numroc(m+iroff, mb_a, MYROW, iarow, NPROW ),
nq0 = numroc(n+icoff, nb_a, MYCOL, iacol, NPCOL),
LOCc(ja+n-1) = numroc(ja+n-1, nb_a, MYCOL, csrc_a, NPCOL),
and numroc, indxg2p are ScaLAPACK tool functions.
```

You can determine MYROW, MYCOL, NPROW and NPCOL by calling the `blacs_gridinfo` function.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

<code>a</code>	The elements on and above the diagonal of <code>sub(A)</code> contain the $\min(m,n)$ -by- n upper trapezoidal matrix R (R is upper triangular if $m \geq n$); the elements below the diagonal, with the array <code>tau</code> , represent the orthogonal/unitary matrix Q as a product of elementary reflectors (see <i>Application Notes</i> below).
<code>ipiv</code>	(local) Array of size <code>LOCc(ja+n-1)</code> . <code>ipiv[i] = k</code> , the local $(i+1)$ -th column of <code>sub(A)*P</code> was the global k -th column of <code>sub(A)</code> ($0 \leq i < \text{LOCc}(ja+n-1)$). <code>ipiv</code> is tied to the distributed matrix A .
<code>tau</code>	(local) Array of size <code>LOCc(ja+min(m, n)-1)</code> . Contains the scalar factor <code>tau</code> of elementary reflectors. <code>tau</code> is tied to the distributed matrix A .
<code>work[0]</code>	On exit, <code>work[0]</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>rwork[0]</code>	On exit, <code>rwork[0]</code> contains the minimum value of <code>lrwork</code> required for optimum performance.
<code>info</code>	(global) = 0, the execution is successful. < 0, if the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then <code>info</code> = $-(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then <code>info</code> = $-i$.

Application Notes

The matrix Q is represented as a product of elementary reflectors

$$Q = H(1)*H(2)*\dots*H(k)$$

where $k = \min(m,n)$.

Each $H(i)$ has the form

$$H = I - \tau v v'$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:m)$ is stored on exit in $A(ia+i:ia+m-1, ja+i-1)$.

The matrix P is represented in $ipiv$ as follows: if $ipiv[j] = i$ then the $(j+1)$ -th column of P is the i -th canonical unit vector ($0 \leq j < LOCC(ja+n-1)$).

p?orgqr

Generates the orthogonal matrix Q of the QR factorization formed by `p?geqrf`.

Syntax

```
void psorgqr (MKL_INT *m , MKL_INT *n , MKL_INT *k , float *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , float *tau , float *work , MKL_INT *lwork , MKL_INT *info );

void pdorgqr (MKL_INT *m , MKL_INT *n , MKL_INT *k , double *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , double *tau , double *work , MKL_INT *lwork , MKL_INT *info );
```

Include Files

- `mkl_scalapack.h`

Description

The `p?orgqr` function generates the whole or part of m -by- n real distributed matrix Q denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal columns, which is defined as the first n columns of a product of k elementary reflectors of order m

$$Q = H(1) * H(2) * \dots * H(k)$$

as returned by `p?geqrf`.

Input Parameters

m	(global) The number of rows in the matrix $\text{sub}(Q)$ ($m \geq 0$).
n	(global) The number of columns in the matrix $\text{sub}(Q)$ ($m \geq n \geq 0$).
k	(global) The number of elementary reflectors whose product defines the matrix Q ($n \geq k \geq 0$).
a	(local) Pointer into the local memory to an array of local size $lld\_a * LOCC(ja+n-1)$. The j -th column of the matrix stored in a must contain the vector that defines the elementary reflector $H(j)$, $ja \leq j \leq ja+k-1$, as returned by <code>p?geqrf</code> in the k columns of its distributed matrix argument $A(ia:*, ja:ja+k-1)$.
ia, ja	(global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix $A(ia:ia+m-1, ja:ja+n-1)$, respectively.
$desca$	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix A .

<i>tau</i>	(local) Array of size $LOCc(ja+k-1)$. Contains the scalar factor $\tau[j]$ of elementary reflectors $H(j+1)$ as returned by <code>p?geqrf</code> ($0 \leq j < LOCc(ja+k-1)$). <i>tau</i> is tied to the distributed matrix <i>A</i> .
<i>work</i>	(local) Workspace array of size of <i>lwork</i> .
<i>lwork</i>	(local or global) size of <i>work</i> . Must be at least $lwork \geq nb\_a * (nqa0 + mpa0 + nb\_a)$, where $iroffa = \text{mod}(ia-1, mb\_a), \quad icoffa = \text{mod}(ja-1, nb\_a),$ $iarow = \text{indxg2p}(ia, mb\_a, MYROW, rsrc\_a, NPROW),$ $iacol = \text{indxg2p}(ja, nb\_a, MYCOL, csrc\_a, NPCOL),$ $mpa0 = \text{numroc}(m+iroffa, mb\_a, MYROW, iarow, NPROW),$ $nqa0 = \text{numroc}(n+icoffa, nb\_a, MYCOL, iacol, NPCOL);$ <i>indxg2p</i> and <i>numroc</i> are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the function <code>blacs_gridinfo</code> . If <i>lwork</i> = -1, then <i>lwork</i> is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by <code>p?xerbla</code> .

Output Parameters

<i>a</i>	Contains the local pieces of the <i>m</i> -by- <i>n</i> distributed matrix <i>Q</i> .
<i>work</i> [0]	On exit, [0] contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	(global) = 0: the execution is successful. < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j</i> - 1, had an illegal value, then <i>info</i> = $-(i*100+j)$; if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

p?ungqr

Generates the complex unitary matrix Q of the QR factorization formed by p?geqrf.

Syntax

```
void pcungqr (MKL_INT *m , MKL_INT *n , MKL_INT *k , MKL_Complex8 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *tau , MKL_Complex8 *work , MKL_INT
*lwork , MKL_INT *info );
```

```
void pzungqr (MKL_INT *m , MKL_INT *n , MKL_INT *k , MKL_Complex16 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *tau , MKL_Complex16 *work , MKL_INT
*lwork , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

This function generates the whole or part of m -by- n complex distributed matrix Q denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal columns, which is defined as the first n columns of a product of k elementary reflectors of order m

$$Q = H(1)*H(2)*...*H(k)$$

as returned by [p?geqrf](#).

Input Parameters

m	(global) The number of rows in the matrix sub(Q); ($m \geq 0$).
n	(global) The number of columns in the matrix sub(Q) ($m \geq n \geq 0$).
k	(global) The number of elementary reflectors whose product defines the matrix Q ($n \geq k \geq 0$).
a	(local) Pointer into the local memory to an array of size $lld\_a * LOCC(ja+n-1)$. The j -th column of the matrix stored in a must contain the vector that defines the elementary reflector $H(j)$, $ja \leq j \leq ja+k-1$, as returned by p?geqrf in the k columns of its distributed matrix argument $A(ia:*, ja:ja+k-1)$.
ia, ja	(global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively.
$desca$	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix A .
tau	(local) Array of size $LOCC(ja+k-1)$. Contains the scalar factor $tau[j]$ of elementary reflectors $H(j+1)$ as returned by p?geqrf ($0 \leq j < LOCC(ja+k-1)$). tau is tied to the distributed matrix A .
$work$	(local) Workspace array of size of $lwork$.
$lwork$	(local or global) size of $work$, must be at least $lwork \geq nb\_a * (nqa0 + mpa0 + nb\_a)$, where $iroffa = \text{mod}(ia-1, mb\_a)$, $icoffa = \text{mod}(ja-1, nb\_a)$, $iarow = \text{indxg2p}(ia, mb\_a, \text{MYROW}, rsrc\_a, \text{NPROW})$, $iacol = \text{indxg2p}(ja, nb\_a, \text{MYCOL}, csrc\_a, \text{NPCOL})$,

```
mpa0 = numroc(m+iroffa, mb_a, MYROW, iarow, NPROW),
```

```
nqa0 = numroc(n+icoffa, nb_a, MYCOL, iacol, NPCOL)
```

indxg2p and *numroc* are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the function *blacs_gridinfo*.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by *pxerbla*.

Output Parameters

<i>a</i>	Contains the local pieces of the <i>m</i> -by- <i>n</i> distributed matrix <i>Q</i> .
<i>work</i> [0]	On exit <i>work</i> [0] contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	(global) = 0: the execution is successful. < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j</i> - 1, had an illegal value, then <i>info</i> = $-(i*100+j)$; if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

p?ormqr

Multiplies a general matrix by the orthogonal matrix Q of the QR factorization formed by p?geqrf.

Syntax

```
void psormqr (char *side , char *trans , MKL_INT *m , MKL_INT *n , MKL_INT *k , float
*a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *tau , float *c , MKL_INT
*ic , MKL_INT *jc , MKL_INT *descc , float *work , MKL_INT *lwork , MKL_INT *info );

void pdormqr (char *side , char *trans , MKL_INT *m , MKL_INT *n , MKL_INT *k , double
*a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *tau , double *c , MKL_INT
*ic , MKL_INT *jc , MKL_INT *descc , double *work , MKL_INT *lwork , MKL_INT *info );
```

Include Files

- `mkl_scalapack.h`

Description

The *p?ormqr* function overwrites the general real *m*-by-*n* distributed matrix sub (C) = C(*ic:ic+m-1,jc:jc+n-1*) with

	<i>side</i> = 'L'	<i>side</i> = 'R'
<i>trans</i> = 'N':	$Q * \text{sub}(C)$	$\text{sub}(C) * Q$
<i>trans</i> = 'T':	$Q^T * \text{sub}(C)$	$\text{sub}(C) * Q^T$

where *Q* is a real orthogonal distributed matrix defined as the product of *k* elementary reflectors

$Q = H(1) H(2) \dots H(k)$

as returned by `p?geqrf`. Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

<i>side</i>	(global) = 'L' : Q or Q^T is applied from the left. = 'R' : Q or Q^T is applied from the right.
<i>trans</i>	(global) = 'N', no transpose, Q is applied. = 'T', transpose, Q^T is applied.
<i>m</i>	(global) The number of rows in the distributed matrix $sub(C)$ ($m \geq 0$).
<i>n</i>	(global) The number of columns in the distributed matrix $sub(C)$ ($n \geq 0$).
<i>k</i>	(global) The number of elementary reflectors whose product defines the matrix Q. Constraints: If $side = 'L'$, $m \geq k \geq 0$ If $side = 'R'$, $n \geq k \geq 0$.
<i>a</i>	(local) Pointer into the local memory to an array of size $lld\_a * LOCC(ja+n-1)$. The j-th column of the matrix stored in <i>a</i> must contain the vector that defines the elementary reflector $H(j)$, $ja \leq j \leq ja+k-1$, as returned by <code>p?geqrf</code> in the k columns of its distributed matrix argument $A(ia:*, ja:ja+k-1)$. $A(ia:*, ja:ja+k-1)$ is modified by the function but restored on exit. If $side = 'L'$, $lld\_a \geq \max(1, LOCr(ia+m-1))$ If $side = 'R'$, $lld\_a \geq \max(1, LOCr(ia+n-1))$
<i>ia, ja</i>	(global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively.
<i>desca</i>	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix A .
<i>tau</i>	(local) Array of size $LOCC(ja+k-1)$. Contains the scalar factor $tau[j]$ of elementary reflectors $H(j+1)$ as returned by <code>p?geqrf</code> ($0 \leq j < LOCC(ja+k-1)$). <i>tau</i> is tied to the distributed matrix A.
<i>c</i>	(local) Pointer into the local memory to an array of local size $lld\_c * LOCC(jc+n-1)$. Contains the local pieces of the distributed matrix $sub(C)$ to be factored.
<i>ic, jc</i>	(global) The row and column indices in the global matrix C indicating the first row and the first column of the matrix $sub(C)$, respectively.

<i>desc</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>C</i> .
<i>work</i>	(local) Workspace array of size of <i>lwork</i> .
<i>lwork</i>	(local or global) size of <i>work</i> , must be at least: <pre> if side = 'L', lwork ≥ max((nb_a*(nb_a-1))/2, (nqc0+mpc0)*nb_a) + nb_a*nb_a else if side = 'R', lwork ≥ max((nb_a*(nb_a-1))/2, (nqc0+max(npa0+numroc(numroc(n +icoffc, nb_a, 0, 0, NPCOL), nb_a, 0, 0, lcmq), mpc0))*nb_a) + nb_a*nb_a end if where lcmq = lcm/NPCOL with lcm = ilcm(NPROW, NPCOL), iroffa = mod(ia-1, mb_a), icoffa = mod(ja-1, nb_a), iarow = indxg2p(ia, mb_a, MYROW, rsrc_a, NPROW), npa0= numroc(n+iroffa, mb_a, MYROW, iarow, NPROW), iroffc = mod(ic-1, mb_c), icoffc = mod(jc-1, nb_c), icrow = indxg2p(ic, mb_c, MYROW, rsrc_c, NPROW), iccol = indxg2p(jc, nb_c, MYCOL, csrc_c, NPCOL), mpc0= numroc(m+iroffc, mb_c, MYROW, icrow, NPROW), nqc0= numroc(n+icoffc, nb_c, MYCOL, iccol, NPCOL), ilcm, indxg2p and numroc are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the function blacs_gridinfo. </pre> If <i>lwork</i> = -1, then <i>lwork</i> is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by <i>p_xerbla</i>.

Output Parameters

<i>c</i>	Overwritten by the product $Q \cdot \text{sub}(C)$, or $Q^T \cdot \text{sub}(C)$, or $\text{sub}(C) \cdot Q^T$, or $\text{sub}(C) \cdot Q$.
<i>work</i> [0]	On exit <i>work</i> [0] contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	(global) = 0: the execution is successful.

< 0 : if the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

p?unmqr

Multiplies a complex matrix by the unitary matrix Q of the QR factorization formed by p?geqrf.

Syntax

```
void pcunmqr (char *side , char *trans , MKL_INT *m , MKL_INT *n , MKL_INT *k ,
MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *tau ,
MKL_Complex8 *c , MKL_INT *ic , MKL_INT *jc , MKL_INT *descc , MKL_Complex8 *work ,
MKL_INT *lwork , MKL_INT *info );

void pzunmqr (char *side , char *trans , MKL_INT *m , MKL_INT *n , MKL_INT *k ,
MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *tau ,
MKL_Complex16 *c , MKL_INT *ic , MKL_INT *jc , MKL_INT *descc , MKL_Complex16 *work ,
MKL_INT *lwork , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

This function overwrites the general complex m -by- n distributed matrix sub (C) = $C(ic:ic+m-1,jc:jc+n-1)$ with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q * sub(C)$	$sub(C) * Q$
$trans = 'T':$	$Q^H * sub(C)$	$sub(C) * Q^H$

where Q is a complex unitary distributed matrix defined as the product of k elementary reflectors

$Q = H(1) H(2) \dots H(k)$ as returned by [p?geqrf](#). Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

$side$	(global) = $'L'$: Q or Q^H is applied from the left. = $'R'$: Q or Q^H is applied from the right.
$trans$	(global) = $'N'$, no transpose, Q is applied. = $'C'$, conjugate transpose, Q^H is applied.
m	(global) The number of rows in the distributed matrix sub(C) ($m \geq 0$).
n	(global) The number of columns in the distributed matrix sub(C) ($n \geq 0$).

<i>k</i>	(global) The number of elementary reflectors whose product defines the matrix <i>Q</i>. Constraints: If <i>side</i> = 'L', $m \geq k \geq 0$ If <i>side</i> = 'R', $n \geq k \geq 0$.
<i>a</i>	(local) Pointer into the local memory to an array of size $lld\_a * LOCC(ja+k-1)$. The <i>j</i>-th column of the matrix stored in <i>a</i> must contain the vector that defines the elementary reflector $H(j)$, $ja \leq j \leq ja+k-1$, as returned by p?geqrf in the <i>k</i> columns of its distributed matrix argument $A(ia:*, ja:ja+k-1)$. $A(ia:*, ja:ja+k-1)$ is modified by the function but restored on exit. If <i>side</i> = 'L', $lld\_a \geq \max(1, LOCr(ia+m-1))$ If <i>side</i> = 'R', $lld\_a \geq \max(1, LOCr(ia+n-1))$
<i>ia, ja</i>	(global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the submatrix <i>A</i>, respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i>. The array descriptor for the distributed matrix <i>A</i>.
<i>tau</i>	(local) Array of size $LOCC(ja+k-1)$. Contains the scalar factor $\tau[j]$ of elementary reflectors $H(j+1)$ as returned by p?geqrf ($0 \leq j < LOCC(ja+k-1)$). <i>tau</i> is tied to the distributed matrix <i>A</i>.
<i>c</i>	(local) Pointer into the local memory to an array of local size $lld\_c * LOCC(jc+n-1)$. Contains the local pieces of the distributed matrix sub(<i>C</i>) to be factored.
<i>ic, jc</i>	(global) The row and column indices in the global matrix <i>C</i> indicating the first row and the first column of the submatrix <i>C</i>, respectively.
<i>descc</i>	(global and local) array of size <i>dlen_</i>. The array descriptor for the distributed matrix <i>C</i>.
<i>work</i>	(local) Workspace array of size of <i>lwork</i>.
<i>lwork</i>	(local or global) size of <i>work</i>, must be at least: If <i>side</i> = 'L', $lwork \geq \max((nb\_a * (nb\_a - 1)) / 2, (nqc0 + mpc0) * nb\_a) + nb\_a * nb\_a$ else if <i>side</i> = 'R', $lwork \geq \max((nb\_a * (nb\_a - 1)) / 2, (nqc0 + \max(npa0 + \text{numroc}(\text{numroc}(n+icoffc, nb\_a, 0, 0, NPCOL), nb\_a, 0, 0, lcmq), mpc0)) * nb\_a) + nb\_a * nb\_a$ end if where

```
lcmq = lcm/NPCOL with lcm = ilcm (NPROW, NPCOL),
iroffa = mod(ia-1, mb_a),
icoffa = mod(ja-1, nb_a),
iarow = indxg2p(ia, mb_a, MYROW, rsrc_a, NPROW),
npa0 = numroc(n+iroffa, mb_a, MYROW, iarow, NPROW),
iroffc = mod(ic-1, mb_c),
icoffc = mod(jc-1, nb_c),
icrow = indxg2p(ic, mb_c, MYROW, rsrc_c, NPROW),
iccol = indxg2p(jc, nb_c, MYCOL, csrc_c, NPCOL),
mpc0 = numroc(m+iroffc, mb_c, MYROW, icrow, NPROW),
nqc0 = numroc(n+icoffc, nb_c, MYCOL, iccol, NPCOL),

ilcm, indxg2p and numroc are ScaLAPACK tool functions; MYROW, MYCOL,
NPROW and NPCOL can be determined by calling the function
blacs_gridinfo.
```

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by p_xerbla.

Output Parameters

<i>c</i>	Overwritten by the product $Q \cdot \text{sub}(C)$, or $Q^H \cdot \text{sub}(C)$, or $\text{sub}(C) \cdot Q^H$, or $\text{sub}(C) \cdot Q$.
<i>work</i> [0]	On exit <i>work</i> [0] contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	(global) = 0: the execution is successful. < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j</i> - 1, had an illegal value, then <i>info</i> = -(<i>i</i> *100+ <i>j</i>); if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

```

```

void pcgelqf (MKL_INT *m , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_Complex8 *tau , MKL_Complex8 *work , MKL_INT *lwork , MKL_INT
*info );

void pzgelqf (MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_Complex16 *tau , MKL_Complex16 *work , MKL_INT *lwork , MKL_INT
*info );

```

Include Files

- mkl_scalapack.h

Description

The `p?gelqf` function computes the LQ factorization of a real/complex distributed m -by- n matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1) = L*Q$.

Input Parameters

<i>m</i>	(global) The number of rows in the distributed submatrix $\text{sub}(A)$ ($m \geq 0$).
<i>n</i>	(global) The number of columns in the distributed submatrix $\text{sub}(A)$ ($n \geq 0$).
<i>a</i>	(local) Pointer into the local memory to an array of local size $lld\_a * LOCc(ja+n-1)$. Contains the local pieces of the distributed matrix $\text{sub}(A)$ to be factored.
<i>ia, ja</i>	(global) The row and column indices in the global array A indicating the first row and the first column of the submatrix $A(ia:ia+m-1, ja:ja+n-1)$, respectively.
<i>desca</i>	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix A .
<i>work</i>	(local) Workspace array of size of <i>lwork</i> .
<i>lwork</i>	(local or global) size of <i>work</i> , must be at least $lwork \geq mb\_a * (mp0 + nq0 + mb\_a)$, where $iroff = \text{mod}(ia-1, mb\_a),$ $icoff = \text{mod}(ja-1, nb\_a),$ $iarow = \text{indxg2p}(ia, mb\_a, MYROW, rsrc\_a, NPROW),$ $iacol = \text{indxg2p}(ja, nb\_a, MYCOL, csrc\_a, NPCOL),$ $mp0 = \text{numroc}(m+iroff, mb\_a, MYROW, iarow, NPROW),$ $nq0 = \text{numroc}(n+icoff, nb\_a, MYCOL, iacol, NPCOL)$ <code>indxg2p</code> and <code>numroc</code> are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the function <code>blacs_gridinfo</code> .

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

<i>a</i>	The elements on and below the diagonal of $\text{sub}(A)$ contain the m -by- $\min(m, n)$ lower trapezoidal matrix L (L is lower trapezoidal if $m \leq n$); the elements above the diagonal, with the array <i>tau</i> , represent the orthogonal/unitary matrix Q as a product of elementary reflectors (see <i>Application Notes</i> below).
<i>tau</i>	(local) Array of size $\text{LOCr}(ia + \min(m, n) - 1)$. Contains the scalar factors of elementary reflectors. <i>tau</i> is tied to the distributed matrix A .
<i>work</i> [0]	On exit, <i>work</i> [0] contains the minimum value of $lwork$ required for optimum performance.
<i>info</i>	(global) = 0: the execution is successful. < 0: if the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then $info = -(i*100 + j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

Application Notes

The matrix Q is represented as a product of elementary reflectors

$$Q = H(ia+k-1)*H(ia+k-2)*...*H(ia),$$

where $k = \min(m, n)$

Each $H(i)$ has the form

$$H(i) = I - \tau * v * v'$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:n)$ is stored on exit in $A(ia+i-1, ja+i:ja+n-1)$, and τ in $\tau[ia+i-2]$.

p?orglq

Generates the real orthogonal matrix Q of the LQ factorization formed by `p?gelqf`.

Syntax

```
void psorglq (MKL_INT *m , MKL_INT *n , MKL_INT *k , float *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , float *tau , float *work , MKL_INT *lwork , MKL_INT *info );

void pdorglq (MKL_INT *m , MKL_INT *n , MKL_INT *k , double *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , double *tau , double *work , MKL_INT *lwork , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The `p?orglq` function generates the whole or part of m -by- n real distributed matrix Q denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal rows, which is defined as the first m rows of a product of k elementary reflectors of order n

$$Q = H(k) * \dots * H(2) * H(1)$$

as returned by `p?gelqf`.

Input Parameters

<i>m</i>	(global) The number of rows in the matrix sub(Q); ($m \geq 0$).
<i>n</i>	(global) The number of columns in the matrix sub(Q) ($n \geq m \geq 0$).
<i>k</i>	(global) The number of elementary reflectors whose product defines the matrix Q ($m \geq k \geq 0$).
<i>a</i>	(local) Pointer into the local memory to an array of local size $lld\_a * LOCC(ja+n-1)$. On entry, the i -th row of the matrix stored in <i>a</i> must contain the vector that defines the elementary reflector $H(i)$, $ia \leq i \leq ia+k-1$, as returned by <code>p?gelqf</code> in the k rows of its distributed matrix argument $A(ia:ia+k-1, ja:*)$.
<i>ia, ja</i>	(global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix $A(ia:ia+m-1, ja:ja+n-1)$, respectively.
<i>desca</i>	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix A .
<i>work</i>	(local) Workspace array of size of <i>lwork</i> .
<i>lwork</i>	(local or global) size of <i>work</i> , must be at least $lwork \geq mb\_a * (mpa0 + nqa0 + mb\_a)$, where $iroffa = \text{mod}(ia-1, mb\_a)$, $icoffa = \text{mod}(ja-1, nb\_a)$, $iarow = \text{indxg2p}(ia, mb\_a, MYROW, rsrc\_a, NPROW)$, $iacol = \text{indxg2p}(ja, nb\_a, MYCOL, csrc\_a, NPCOL)$, $mpa0 = \text{numroc}(m + iroffa, mb\_a, MYROW, iarow, NPROW)$,

```
nqa0 = numroc(n+icoffa, nb_a, MYCOL, iacol, NPCOL)
```

NOTE

`mod(x, y)` is the integer remainder of x/y .

`indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the function `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by [pxerbla](#).

Output Parameters

<code>a</code>	Contains the local pieces of the m -by- n distributed matrix Q to be factored.
<code>tau</code>	(local) Array of size <code>LOCr(ia+k-1)</code> . Contains the scalar factors <code>tau[j]</code> of elementary reflectors $H(j+1)$, $0 \leq j < \text{LOCr}(ia+k-1)$. <code>tau</code> is tied to the distributed matrix A .
<code>work[0]</code>	On exit, <code>work[0]</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) = 0: the execution is successful. < 0: if the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then <code>info = -(i*100+j)</code> ; if the i -th argument is a scalar and had an illegal value, then <code>info = -i</code> .

p?unglq

Generates the unitary matrix Q of the LQ factorization formed by [p?gelqf](#).

Syntax

```
void pcunglq (MKL_INT *m , MKL_INT *n , MKL_INT *k , MKL_Complex8 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *tau , MKL_Complex8 *work , MKL_INT
*lwork , MKL_INT *info );
```

```
void pzunglq (MKL_INT *m , MKL_INT *n , MKL_INT *k , MKL_Complex16 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *tau , MKL_Complex16 *work , MKL_INT
*lwork , MKL_INT *info );
```

Include Files

- `mkl_scalapack.h`

Description

This function generates the whole or part of m -by- n complex distributed matrix Q denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal rows, which is defined as the first m rows of a product of k elementary reflectors of order n

$Q = (H(k))^H \dots (H(2))^H (H(1))^H$ as returned by `p?gelqf`.

Input Parameters

m	(global) The number of rows in the matrix sub(Q) ($m \geq 0$).
n	(global) The number of columns in the matrix sub(Q) ($n \geq m \geq 0$).
k	(global) The number of elementary reflectors whose product defines the matrix Q ($m \geq k \geq 0$).
a	(local) Pointer into the local memory to an array of local size $lld\_a * LOCC(ja+n-1)$. On entry, the i -th row of the matrix stored in a must contain the vector that defines the elementary reflector $H(i)$, $ia \leq i \leq ia+k-1$, as returned by <code>p?gelqf</code> in the k rows of its distributed matrix argument $A(ia:ia+k-1, ja:*)$.
ia, ja	(global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix $A(ia:ia+m-1, ja:ja+n-1)$, respectively.
$desca$	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix A .
τ	(local) Array of size $LOCr(ia+k-1)$. Contains the scalar factors $\tau[j]$ of elementary reflectors $H(j+1)$, $0 \leq j < LOCr(ia+k-1)$. τ is tied to the distributed matrix A .
$work$	(local) Workspace array of size of $lwork$.
$lwork$	(local or global) size of $work$, must be at least $lwork \geq mb\_a * (mpa0 + nqa0 + mb\_a)$, where $iroffa = \text{mod}(ia-1, mb\_a),$ $icoffa = \text{mod}(ja-1, nb\_a),$ $iarow = \text{indxg2p}(ia, mb\_a, MYROW, rsrc\_a, NPROW),$ $iacol = \text{indxg2p}(ja, nb\_a, MYCOL, csrc\_a, NPCOL),$ $mpa0 = \text{numroc}(m + iroffa, mb\_a, MYROW, iarow, NPROW),$ $nqa0 = \text{numroc}(n + icoffa, nb\_a, MYCOL, iacol, NPCOL)$ $\text{indxg2p} \text{ and } \text{numroc} \text{ are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the function } \text{blacs\_gridinfo}.$

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

a	Contains the local pieces of the m -by- n distributed matrix Q to be factored.
$work[0]$	On exit, $work[0]$ contains the minimum value of $lwork$ required for optimum performance.
$info$	(global) = 0: the execution is successful. < 0: if the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

p?ormlq

Multiplies a general matrix by the orthogonal matrix Q of the LQ factorization formed by p?gelqf.

Syntax

```
void psormlq (char *side , char *trans , MKL_INT *m , MKL_INT *n , MKL_INT *k , float
*a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *tau , float *c , MKL_INT
*ic , MKL_INT *jc , MKL_INT *descc , float *work , MKL_INT *lwork , MKL_INT *info );

void pdormlq (char *side , char *trans , MKL_INT *m , MKL_INT *n , MKL_INT *k , double
*a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *tau , double *c , MKL_INT
*ic , MKL_INT *jc , MKL_INT *descc , double *work , MKL_INT *lwork , MKL_INT *info );
```

Include Files

- `mk1_scalapack.h`

Description

The `p?ormlq` function overwrites the general real m -by- n distributed matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q * \text{sub}(C)$	$\text{sub}(C) * Q$
$trans = 'T':$	$Q^T * \text{sub}(C)$	$\text{sub}(C) * Q^T$

where Q is a real orthogonal distributed matrix defined as the product of k elementary reflectors

$$Q = H(k) \dots H(2) H(1)$$

as returned by `p?gelqf`. Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

<i>side</i>	(global) = 'L': Q or Q^T is applied from the left. = 'R': Q or Q^T is applied from the right.
<i>trans</i>	(global) = 'N', no transpose, Q is applied. = 'T', transpose, Q^T is applied.
<i>m</i>	(global) The number of rows in the distributed matrix $sub(C)$ ($m \geq 0$).
<i>n</i>	(global) The number of columns in the distributed matrix $sub(C)$ ($n \geq 0$).
<i>k</i>	(global) The number of elementary reflectors whose product defines the matrix Q . Constraints: If $side = 'L'$, $m \geq k \geq 0$ If $side = 'R'$, $n \geq k \geq 0$.
<i>a</i>	(local) Pointer into the local memory to an array of size $lld\_a * LOCC(ja+m-1)$, if $side = 'L'$ and $lld\_a * LOCC(ja+n-1)$, if $side = 'R'$. The i -th row of the matrix stored in a must contain the vector that defines the elementary reflector $H(i)$, $ia \leq i \leq ia+k-1$, as returned by <code>p?gelqf</code> in the k rows of its distributed matrix argument $A(ia:ia+k-1, ja:*)$. $A(ia:ia+k-1, ja:*)$ is modified by the function but restored on exit.
<i>ia, ja</i>	(global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively.
<i>desca</i>	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix A .
<i>tau</i>	(local) Array of size $LOCC(ja+k-1)$. Contains the scalar factor $tau[j]$ of elementary reflectors $H(j+1)$ as returned by <code>p?gelqf</code> ($0 \leq j < LOCC(ja+k-1)$). tau is tied to the distributed matrix A .
<i>c</i>	(local) Pointer into the local memory to an array of local size $lld\_c * LOCC(jc+n-1)$. Contains the local pieces of the distributed matrix $sub(C)$ to be factored.
<i>ic, jc</i>	(global) The row and column indices in the global matrix C indicating the first row and the first column of the submatrix C , respectively.
<i>desc</i>	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix C .

work (local)
Workspace array of size of *lwork*.

lwork (local or global) size of the array *work*; must be at least:

```
If side = 'L',
lwork ≥ max((mb_a*(mb_a-1))/2, (mpc0+maxmqa0)+ numroc(numroc(m
+ iroffc, mb_a, 0, 0, NPROW), mb_a, 0, 0, lcmp), nqc0))*
mb_a) + mb_a*mb_a
else if side = 'R',
lwork ≥ max((mb_a*(mb_a-1))/2, (mpc0+nqc0)*mb_a + mb_a*mb_a
end if
where
lcmp = lcm/NPROW with lcm = ilcm (NPROW, NPCOL),
iroffa = mod(ia-1, mb_a),
icoffa = mod(ja-1, nb_a),
iacol = indxg2p(ja, nb_a, MYCOL, csrc_a, NPCOL),
mqa0 = numroc(m+icoffa, nb_a, MYCOL, iacol, NPCOL),
iroffc = mod(ic-1, mb_c),
icoffc = mod(jc-1, nb_c),
icrow = indxg2p(ic, mb_c, MYROW, rsrc_c, NPROW),
iccol = indxg2p(jc, nb_c, MYCOL, csrc_c, NPCOL),
mpc0 = numroc(m+iroffc, mb_c, MYROW, icrow, NPROW),
nqc0 = numroc(n+icoffc, nb_c, MYCOL, iccol, NPCOL),
```

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

ilcm, *indxg2p* and *numroc* are ScaLAPACK tool functions; *MYROW*, *MYCOL*, *NPROW* and *NPCOL* can be determined by calling the function *blacs_gridinfo*.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by *pxerbla*.

Output Parameters

c Overwritten by the product $Q \cdot \text{sub}(C)$, or $Q' \cdot \text{sub}(C)$, or $\text{sub}(C) \cdot Q'$, or $\text{sub}(C) \cdot Q$

work[0] On exit *work[0]* contains the minimum value of *lwork* required for optimum performance.

info (global)

= 0: the execution is successful.

< 0: if the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

Description

This function overwrites the general complex m -by- n distributed matrix $sub(C) = C(ic:ic+m-1,jc:jc+n-1)$ with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q * sub(C)$	$sub(C) * Q$
$trans = 'T':$	$Q^H * sub(C)$	$sub(C) * Q^H$

where Q is a complex unitary distributed matrix defined as the product of k elementary reflectors

$$Q = H(k)' \dots H(2)' H(1)'$$

as returned by [p?gelqf](#). Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

$side$	(global) = 'L': Q or Q^H is applied from the left. = 'R': Q or Q^H is applied from the right.
$trans$	(global) = 'N', no transpose, Q is applied. = 'C', conjugate transpose, Q^H is applied.
m	(global) The number of rows in the distributed matrix $sub(C)$ ($m \geq 0$).

<i>n</i>	(global) The number of columns in the distributed matrix $\text{sub}(C)$ ($n \geq 0$).
<i>k</i>	(global) The number of elementary reflectors whose product defines the matrix Q. Constraints: If <i>side</i> = 'L', $m \geq k \geq 0$ If <i>side</i> = 'R', $n \geq k \geq 0$.
<i>a</i>	(local) Pointer into the local memory to an array of size $\text{lld\_a} * \text{LOCc}(ja+m-1)$, if <i>side</i> = 'L' and $\text{lld\_a} * \text{LOCc}(ja+n-1)$, if <i>side</i> = 'R', where $\text{lld\_a} \geq \max(1, \text{LOCr}(ia+k-1))$. The <i>i</i>-th column of the matrix stored in <i>a</i> must contain the vector that defines the elementary reflector $H(i)$, $ia \leq i \leq ia+k-1$, as returned by <code>p?gelqf</code> in the <i>k</i> rows of its distributed matrix argument $A(ia:ia+k-1, ja:*)$. $A(ia:ia+k-1, ja:*)$ is modified by the function but restored on exit.
<i>ia, ja</i>	(global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix A .
<i>tau</i>	(local) Array of size $\text{LOCc}(ia+k-1)$. Contains the scalar factor $\tau[j]$ of elementary reflectors $H(j+1)$ as returned by <code>p?gelqf</code> ($0 \leq j < \text{LOCc}(ia+k-1)$). <i>tau</i> is tied to the distributed matrix A.
<i>c</i>	(local) Pointer into the local memory to an array of local size $\text{lld\_c} * \text{LOCc}(jc+n-1)$. Contains the local pieces of the distributed matrix $\text{sub}(C)$ to be factored.
<i>ic, jc</i>	(global) The row and column indices in the global matrix C indicating the first row and the first column of the submatrix C , respectively.
<i>descc</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix C .
<i>work</i>	(local) Workspace array of size of <i>lwork</i>.
<i>lwork</i>	(local or global) size of the array <i>work</i>; must be at least: If <i>side</i> = 'L', $\text{lwork} \geq \max((\text{mb\_a} * (\text{mb\_a} - 1)) / 2, (\text{mpc0} + \text{maxmqa0}) + \text{numroc}(\text{numroc}(m + \text{irowfc}, \text{mb\_a}, 0, 0, \text{NPROW}), \text{mb\_a}, 0, 0, \text{lcmp}), \text{nqc0})) * \text{mb\_a} + \text{mb\_a} * \text{mb\_a}$ else if <i>side</i> = 'R', $\text{lwork} \geq \max((\text{mb\_a} * (\text{mb\_a} - 1)) / 2, (\text{mpc0} + \text{nqc0}) * \text{mb\_a} + \text{mb\_a} * \text{mb\_a})$ end if

where

```
lcmp = lcm/NPROW with lcm = ilcm (NPROW, NPCOL),
iroffa = mod(ia-1, mb_a),
icoffa = mod(ja-1, nb_a),
iacol = indxg2p(ja, nb_a, MYCOL, csrc_a, NPCOL),
mqa0 = numroc(m + icoffa, nb_a, MYCOL, iacol, NPCOL),
iroffc = mod(ic-1, mb_c),
icoffc = mod(jc-1, nb_c),
icrow = indxg2p(ic, mb_c, MYROW, rsrc_c, NPROW),
iccol = indxg2p(jc, nb_c, MYCOL, csrc_c, NPCOL),
mpc0 = numroc(m+iroffc, mb_c, MYROW, icrow, NPROW),
nqc0 = numroc(n+icoffc, nb_c, MYCOL, iccol, NPCOL),
```

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

`ilcm`, `indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the function `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

<code>c</code>	Overwritten by the product $Q \cdot \text{sub}(C)$, or $Q' \cdot \text{sub}(C)$, or $\text{sub}(C) \cdot Q'$, or $\text{sub}(C) \cdot Q$
<code>work[0]</code>	On exit <code>work[0]</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) = 0: the execution is successful. < 0: if the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then <code>info</code> = $-(i \cdot 100 + j)$; if the i -th argument is a scalar and had an illegal value, then <code>info</code> = $-i$.

MKL_INT *desca , double *tau , double *work , MKL_INT *lwork , MKL_INT *info );

void pcgeqlf (MKL_INT *m , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_Complex8 *tau , MKL_Complex8 *work , MKL_INT *lwork , MKL_INT
*info );

void pzgeqlf (MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_Complex16 *tau , MKL_Complex16 *work , MKL_INT *lwork , MKL_INT
*info );
```

Include Files

- mkl_scalapack.h

Description

The `p?geqlf` function forms the *QL* factorization of a real/complex distributed *m*-by-*n* matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1) = Q^*L$.

Input Parameters

<i>m</i>	(global) The number of rows in the matrix $\text{sub}(Q)$; ($m \geq 0$).
<i>n</i>	(global) The number of columns in the matrix $\text{sub}(Q)$ ($n \geq 0$).
<i>a</i>	(local) Pointer into the local memory to an array of local size $lld\_a * LOCc(ja+n-1)$. Contains the local pieces of the distributed matrix $\text{sub}(A)$ to be factored.
<i>ia, ja</i>	(global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the submatrix $A(ia:ia+m-1, ja:ja+n-1)$, respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .
<i>work</i>	(local) Workspace array of size of <i>lwork</i> .
<i>lwork</i>	(local or global) size of <i>work</i> , must be at least $lwork \geq nb\_a * (mp0 + nq0 + nb\_a)$, where $iroff = \text{mod}(ia-1, mb\_a),$ $icoff = \text{mod}(ja-1, nb\_a),$ $iarow = \text{indxg2p}(ia, mb\_a, MYROW, rsrc\_a, NPROW),$ $iacol = \text{indxg2p}(ja, nb\_a, MYCOL, csrc\_a, NPCOL),$ $mp0 = \text{numroc}(m+iroff, mb\_a, MYROW, iarow, NPROW),$ $nq0 = \text{numroc}(n+icoff, nb\_a, MYCOL, iacol, NPCOL)$

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

`numroc` and `indxg2p` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the function `blacs_gridinfo`.

If `lwork` = -1, then `lwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

<code>a</code>	On exit, if $m \geq n$, the lower triangle of the distributed submatrix $A(ia+m-n:ia+m-1, ja:ja+n-1)$ contains the n -by- n lower triangular matrix L ; if $m \leq n$, the elements on and below the $(n-m)$ -th superdiagonal contain the m -by- n lower trapezoidal matrix L ; the remaining elements, with the array <code>tau</code> , represent the orthogonal/unitary matrix Q as a product of elementary reflectors (see <i>Application Notes</i> below).
<code>tau</code>	(local) Array of size <code>LOCc(ja+n-1)</code> . Contains the scalar factors of elementary reflectors. <code>tau</code> is tied to the distributed matrix A .
<code>work[0]</code>	On exit, <code>work[0]</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) = 0: the execution is successful. < 0: if the i -th argument is an array and the j -th entry, indexed $j-1$, had an illegal value, then <code>info</code> = $-(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then <code>info</code> = $-i$.

Application Notes

The matrix Q is represented as a product of elementary reflectors

$$Q = H(ja+k-1) \dots H(ja+1) H(ja)$$

where $k = \min(m, n)$

Each $H(i)$ has the form

$$H(i) = I - \tau v v'$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(m-k+i+1:m) = 0$ and $v(m-k+i) = 1$; $v(1:m-k+i-1)$ is stored on exit in $A(ia:ia+m-k+i-2, ja+n-k+i-1)$, and τ in `tau[ja+n-k+i-2]`.

p?orgql

Generates the orthogonal matrix Q of the QL factorization formed by p?geqlf.

Syntax

```
void psorgql (MKL_INT *m , MKL_INT *n , MKL_INT *k , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *tau , float *work , MKL_INT *lwork , MKL_INT *info );

void pdorgql (MKL_INT *m , MKL_INT *n , MKL_INT *k , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *tau , double *work , MKL_INT *lwork , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The p?orgql function generates the whole or part of m -by- n real distributed matrix Q denoting $A(ia:ia+m-1,ja:ja+n-1)$ with orthonormal rows, which is defined as the first m rows of a product of k elementary reflectors of order n

$$Q = H(k) * \dots * H(2) * H(1)$$

as returned by p?geqlf.

Input Parameters

m	(global) The number of rows in the matrix sub(Q), ($m \geq 0$).
n	(global) The number of columns in the matrix sub(Q), ($m \geq n \geq 0$).
k	(global) The number of elementary reflectors whose product defines the matrix Q ($n \geq k \geq 0$).
a	(local) Pointer into the local memory to an array of local size $lld\_a * LOCC(ja+n-1)$. On entry, the j -th column of the matrix stored in a must contain the vector that defines the elementary reflector $H(j)$, $ja+n-k \leq j \leq ja+n-1$, as returned by p?geqlf in the k columns of its distributed matrix argument $A(ia:*,ja+n-k:ja+n-1)$.
ia, ja	(global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix $A(ia:ia+m-1,ja:ja+n-1)$, respectively.
$desca$	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix A .
tau	(local) Array of size $LOCC(ja+n-1)$. Contains the scalar factors $tau[j]$ of elementary reflectors $H(j+1)$, $0 \leq j < LOCr(ia+n-1)$. tau is tied to the distributed matrix A .
$work$	(local) Workspace array of size of $lwork$.

lwork (local or global) size of *work*, must be at least
 $lwork \geq nb\_a * (nqa0 + mpa0 + nb\_a)$, where
 $iroffa = \text{mod}(ia-1, mb\_a)$,
 $icoffa = \text{mod}(ja-1, nb\_a)$,
 $iarow = \text{indxg2p}(ia, mb\_a, MYROW, rsrc\_a, NPROW)$,
 $iacol = \text{indxg2p}(ja, nb\_a, MYCOL, csrc\_a, NPCOL)$,
 $mpa0 = \text{numroc}(m + iroffa, mb\_a, MYROW, iarow, NPROW)$,
 $nqa0 = \text{numroc}(n + icoffa, nb\_a, MYCOL, iacol, NPCOL)$

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

`indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the function `blacs_gridinfo`.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `p?xerbla`.

Output Parameters

a Contains the local pieces of the m -by- n distributed matrix *Q* to be factored.

work[0] On exit, *work*[0] contains the minimum value of *lwork* required for optimum performance.

info (global)
 = 0: the execution is successful.
 < 0: if the *i*-th argument is an array and the *j*-th entry, indexed *j* - 1, had an illegal value, then *info* = $-(i*100+j)$; if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

*ic , MKL_INT *jc , MKL_INT *descc , double *work , MKL_INT *lwork , MKL_INT *info );
```

Include Files

- `mkl_scalapack.h`

Description

The `p?ormql` function overwrites the general real m -by- n distributed matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q * \text{sub}(C)$	$\text{sub}(C) * Q$
$trans = 'T':$	$Q^T * \text{sub}(C)$	$\text{sub}(C) * Q^T$

where Q is a real orthogonal distributed matrix defined as the product of k elementary reflectors

$$Q = H(k)' \dots H(2)' H(1)'$$

as returned by `p?geqlf`. Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

<i>side</i>	(global) = 'L': Q or Q^T is applied from the left. = 'R': Q or Q^T is applied from the right.
<i>trans</i>	(global) = 'N', no transpose, Q is applied. = 'T', transpose, Q^T is applied.
<i>m</i>	(global) The number of rows in the distributed matrix $\text{sub}(C)$, ($m \geq 0$).
<i>n</i>	(global) The number of columns in the distributed matrix $\text{sub}(C)$, ($n \geq 0$).
<i>k</i>	(global) The number of elementary reflectors whose product defines the matrix Q. Constraints: If <i>side</i> = 'L', $m \geq k \geq 0$ If <i>side</i> = 'R', $n \geq k \geq 0$.
<i>a</i>	(local) Pointer into the local memory to an array of size $lld\_a * LOCc(ja+k-1)$. The j-th column of the matrix stored in <i>a</i> must contain the vector that defines the elementary reflector $H(j)$, $ja \leq j \leq ja+k-1$, as returned by <code>p?gelqf</code> in the k columns of its distributed matrix argument $A(ia:*, ja:ja+k-1)$. $A(ia:*, ja:ja+k-1)$ is modified by the function but restored on exit. If <i>side</i> = 'L', $lld\_a \geq \max(1, LOCr(ia+m-1))$, If <i>side</i> = 'R', $lld\_a \geq \max(1, LOCr(ia+n-1))$.
<i>ia, ja</i>	(global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix A .
<i>tau</i>	(local) Array of size $LOCc(ja+n-1)$. Contains the scalar factor $\tau[j]$ of elementary reflectors $H(j+1)$ as returned by <code>p?geqlf</code> ($0 \leq j < LOCc(ja+k-1)$). <i>tau</i> is tied to the distributed matrix A.
<i>c</i>	(local) Pointer into the local memory to an array of local size $lld\_c * LOCc(jc+n-1)$. Contains the local pieces of the distributed matrix $\text{sub}(C)$ to be factored.
<i>ic, jc</i>	(global) The row and column indices in the global matrix C indicating the first row and the first column of the submatrix C , respectively.
<i>desc</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix C .

work (local)
Workspace array of size of *lwork*.

lwork (local or global) dimension of *work*, must be at least:

If *side* = 'L',
 $lwork \geq \max((nb\_a * (nb\_a - 1)) / 2, (nqc0 + mpc0) * nb\_a + nb\_a * nb\_a)$

else if *side* = 'R',
 $lwork \geq \max((nb\_a * (nb\_a - 1)) / 2, (nqc0 + \max(npa0 + \text{numroc}(\text{numroc}(n + iroffc, nb\_a, 0, 0, NPCOL), nb\_a, 0, 0, lcmq), mpc0)) * nb\_a + nb\_a * nb\_a)$

end if

where

$lcmq = lcm / NPCOL$ with $lcm = ilcm(NPROW, NPCOL)$,
 $iroffa = \text{mod}(ia - 1, mb\_a)$,
 $icoffa = \text{mod}(ja - 1, nb\_a)$,
 $iarow = \text{indxg2p}(ia, mb\_a, MYROW, rsrc\_a, NPROW)$,
 $npa0 = \text{numroc}(n + iroffa, mb\_a, MYROW, iarow, NPROW)$,
 $iroffc = \text{mod}(ic - 1, mb\_c)$,
 $icoffc = \text{mod}(jc - 1, nb\_c)$,
 $icrow = \text{indxg2p}(ic, mb\_c, MYROW, rsrc\_c, NPROW)$,
 $iccol = \text{indxg2p}(jc, nb\_c, MYCOL, csrc\_c, NPCOL)$,
 $mpc0 = \text{numroc}(m + iroffc, mb\_c, MYROW, icrow, NPROW)$,
 $nqc0 = \text{numroc}(n + icoffc, nb\_c, MYCOL, iccol, NPCOL)$,

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

$ilcm$, indxg2p and numroc are ScaLAPACK tool functions; $MYROW$, $MYCOL$, $NPROW$ and $NPCOL$ can be determined by calling the function `blacs_gridinfo`.

If $lwork = -1$, then *lwork* is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `p_xerbla`.

Output Parameters

c Overwritten by the product $Q^* \text{sub}(C)$, or $Q'^* \text{sub}(C)$, or $\text{sub}(C)^* Q'$, or $\text{sub}(C)^* Q$

work[0] On exit *work*[0] contains the minimum value of *lwork* required for optimum performance.

info (global)

= 0: the execution is successful.

< 0: if the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

Description

This function overwrites the general complex m -by- n distributed matrix $sub(C) = C(ic:ic+m-1,jc:jc+n-1)$ with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q * sub(C)$	$sub(C) * Q$
$trans = 'C':$	$Q^H * sub(C)$	$sub(C) * Q^H$

where Q is a complex unitary distributed matrix defined as the product of k elementary reflectors

$$Q = H(k)' \dots H(2)' H(1)'$$

as returned by [p?geqlf](#). Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

$side$	(global) = 'L': Q or Q^H is applied from the left. = 'R': Q or Q^H is applied from the right.
$trans$	(global) = 'N', no transpose, Q is applied. = 'C', conjugate transpose, Q^H is applied.
m	(global) The number of rows in the distributed matrix $sub(C)$ ($m \geq 0$).

<i>n</i>	(global) The number of columns in the distributed matrix $\text{sub}(C)$ ($n \geq 0$).
<i>k</i>	(global) The number of elementary reflectors whose product defines the matrix Q. Constraints: If <i>side</i> = 'L', $m \geq k \geq 0$ If <i>side</i> = 'R', $n \geq k \geq 0$.
<i>a</i>	(local) Pointer into the local memory to an array of size $\text{lld\_a} * \text{LOCc}(j_a + k - 1)$. The j-th column of the matrix stored in <i>a</i> must contain the vector that defines the elementary reflector $H(j)$, $j_a \leq j \leq j_a + k - 1$, as returned by p?geqlf in the k columns of its distributed matrix argument $A(\text{ia} : *, j_a : j_a + k - 1)$. $A(\text{ia} : *, j_a : j_a + k - 1)$ is modified by the function but restored on exit. If <i>side</i> = 'L', $\text{lld\_a} \geq \max(1, \text{LOCr}(\text{ia} + m - 1))$, If <i>side</i> = 'R', $\text{lld\_a} \geq \max(1, \text{LOCr}(\text{ia} + n - 1))$.
<i>ia, ja</i>	(global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix A .
<i>tau</i>	(local) Array of size $\text{LOCc}(\text{ia} + n - 1)$. Contains the scalar factor $\text{tau}[j]$ of elementary reflectors $H(j+1)$ as returned by p?geqlf ($0 \leq j < \text{LOCc}(\text{ia} + n - 1)$). <i>tau</i> is tied to the distributed matrix A.
<i>c</i>	(local) Pointer into the local memory to an array of local size $\text{lld\_c} * \text{LOCc}(j_c + n - 1)$. Contains the local pieces of the distributed matrix $\text{sub}(C)$ to be factored.
<i>ic, jc</i>	(global) The row and column indices in the global matrix C indicating the first row and the first column of the submatrix C , respectively.
<i>descc</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix C .
<i>work</i>	(local) Workspace array of size of <i>lwork</i>.
<i>lwork</i>	(local or global) size of <i>work</i>, must be at least: If <i>side</i> = 'L', $\text{lwork} \geq \max((\text{nb\_a} * (\text{nb\_a} - 1)) / 2, (\text{nqc0} + \text{mpc0}) * \text{nb\_a} + \text{nb\_a} * \text{nb\_a})$ else if <i>side</i> = 'R', $\text{lwork} \geq \max((\text{nb\_a} * (\text{nb\_a} - 1)) / 2, (\text{nqc0} + \text{maxnpa0}) + \text{numroc}(\text{numroc}(n + \text{icoffc}, \text{nb\_a}, 0, 0, \text{NPCOL}), \text{nb\_a}, 0, 0, \text{lcmq}), \text{mpc0})) * \text{nb\_a} + \text{nb\_a} * \text{nb\_a})$

```

end if
where
lcmp = lcm/NPCOL with lcm = ilcm (NPROW, NPCOL),
iroffa = mod(ia-1, mb_a),
icoffa = mod(ja-1, nb_a),
iarow = indxg2p(ia, mb_a, MYROW, rsrc_a, NPROW),
npa0 = numroc(n + iroffa, mb_a, MYROW, iarow, NPROW),
iroffc = mod(ic-1, mb_c),
icoffc = mod(jc-1, nb_c),
icrow = indxg2p(ic, mb_c, MYROW, rsrc_c, NPROW),
iccol = indxg2p(jc, nb_c, MYCOL, csrc_c, NPCOL),
mpc0 = numroc(m+iroffc, mb_c, MYROW, icrow, NPROW),
nqc0 = numroc(n+icoffc, nb_c, MYCOL, iccol, NPCOL),

```

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

`ilcm`, `indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the function `blacs_gridinfo`.

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

If `lwork` = -1, then `lwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

<code>c</code>	Overwritten by the product $Q^* \text{sub}(C)$, or $Q' \text{sub}(C)$, or $\text{sub}(C)^* Q'$, or $\text{sub}(C)^* Q$
<code>work[0]</code>	On exit <code>work[0]</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) = 0: the execution is successful. < 0: if the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then <code>info</code> = $-(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then <code>info</code> = $-i$.

p?gerqf

Computes the RQ factorization of a general rectangular matrix.

Syntax

```
void psgerqf (MKL_INT *m , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , float *tau , float *work , MKL_INT *lwork , MKL_INT *info );

void pdgerqf (MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *tau , double *work , MKL_INT *lwork , MKL_INT *info );

void pcgerqf (MKL_INT *m , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_Complex8 *tau , MKL_Complex8 *work , MKL_INT *lwork , MKL_INT
*info );

void pzgerqf (MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_Complex16 *tau , MKL_Complex16 *work , MKL_INT *lwork , MKL_INT
*info );
```

Include Files

- mkl_scalapack.h

Description

The p?gerqf function forms the QR factorization of a general m -by- n distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$ as

$$A = R * Q$$

Input Parameters

<i>m</i>	(global) The number of rows in the distributed matrix $\text{sub}(A)$; ($m \geq 0$).
<i>n</i>	(global) The number of columns in the distributed matrix $\text{sub}(A)$; ($n \geq 0$).
<i>a</i>	(local) Pointer into the local memory to an array of local size $lld\_a * LOCc(ja+n-1)$. Contains the local pieces of the distributed matrix $\text{sub}(A)$ to be factored.
<i>ia, ja</i>	(global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix $A(ia:ia+m-1, ja:ja+n-1)$, respectively.
<i>desca</i>	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix A
<i>work</i>	(local). Workspace array of size $lwork$.
<i>lwork</i>	(local or global) size of <i>work</i> , must be at least $lwork \geq mb\_a * (mp0 + nq0 + mb\_a)$, where $iroff = \text{mod}(ia-1, mb\_a)$, $icoff = \text{mod}(ja-1, nb\_a)$, $iarow = \text{indxg2p}(ia, mb\_a, MYROW, rsrc\_a, NPROW)$,

```
iacol = indxg2p(ja, nb_a, MYCOL, csrc_a, NPCOL),
mp0 = numroc(m+iroff, mb_a, MYROW, iarow, NPROW),
```

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

$nq0 = \text{numroc}(n+icoff, nb_a, MYCOL, iacol, NPCOL)$ and numroc , indxg2p are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the function `blacs_gridinfo`.

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

<i>a</i>	On exit, if $m \leq n$, the upper triangle of $A(ia:ia+m-1, ja:ja+n-1)$ contains the m -by- m upper triangular matrix R ; if $m \geq n$, the elements on and above the $(m - n)$ -th subdiagonal contain the m -by- n upper trapezoidal matrix R ; the remaining elements, with the array <i>tau</i> , represent the orthogonal/unitary matrix Q as a product of elementary reflectors (see <i>Application Notes</i> below).
<i>tau</i>	(local) Array of size $LOCr(ia+m-1)$. Contains the scalar factor of elementary reflectors. <i>tau</i> is tied to the distributed matrix A .
<i>work</i> [0]	On exit, <i>work</i> [0] contains the minimum value of $lwork$ required for optimum performance.
<i>info</i>	(global) = 0, the execution is successful. < 0, if the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

Application Notes

The matrix Q is represented as a product of elementary reflectors

$$Q = H(ia) * H(ia+1) * \dots * H(ia+k-1),$$

where $k = \min(m, n)$.

Each $H(i)$ has the form

$$H(i) = I - \tau * v * v'$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(n-k+i+1:n) = 0$ and $v(n-k+i) = 1$; $v(1:n-k+i-1)$ is stored on exit in $A(ia+m-k+i-1, ja:ja+n-k+i-2)$, and τ in $\tau[ia+m-k+i-2]$.

p?orgrq

Generates the orthogonal matrix Q of the RQ factorization formed by `p?gerqf`.

Syntax

```
void psorgrq (MKL_INT *m , MKL_INT *n , MKL_INT *k , float *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , float *tau , float *work , MKL_INT *lwork , MKL_INT *info );

void pdorgrq (MKL_INT *m , MKL_INT *n , MKL_INT *k , double *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , double *tau , double *work , MKL_INT *lwork , MKL_INT *info );
```

Include Files

- `mkl_scalapack.h`

Description

The `p?orgrq` function generates the whole or part of m -by- n real distributed matrix Q denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal rows that is defined as the last m rows of a product of k elementary reflectors of order n

$$Q = H(1) * H(2) * \dots * H(k)$$

as returned by `p?gerqf`.

Input Parameters

m	(global) The number of rows in the matrix $\text{sub}(Q)$, ($m \geq 0$).
n	(global) The number of columns in the matrix $\text{sub}(Q)$, ($n \geq m \geq 0$).
k	(global) The number of elementary reflectors whose product defines the matrix Q ($m \geq k \geq 0$).
a	(local) Pointer into the local memory to an array of local size $lld\_a * LOCC(ja+n-1)$. The i -th row of the matrix stored in a must contain the vector that defines the elementary reflector $H(i)$, $ia \leq i \leq ia+m-1$, as returned by <code>p?gerqf</code> in the k rows of its distributed matrix argument $A(ia+m-k:ia+m-1, ja:*)$.
ia, ja	(global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively.
$desca$	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix A .
tau	(local) Array of size $LOCC(ja+k-1)$. Contains the scalar factor $tau[i]$ of elementary reflectors $H(i+1)$ as returned by <code>p?gerqf</code> , $0 \leq i < LOCr(ja+k-1)$. tau is tied to the distributed matrix A .
$work$	(local) Workspace array of size of $lwork$.

lwork (local or global) size of *work*, must be at least $lwork \geq mb\_a * (mpa0 + nqa0 + mb\_a)$, where

```

iroffa = mod(ia-1, mb_a),
icoffa = mod(ja-1, nb_a),
iarow = indxg2p(ia, mb_a, MYROW, rsrc_a, NPROW),
iacol = indxg2p(ja, nb_a, MYCOL, csrc_a, NPCOL),
mpa0 = numroc(m+iroffa, mb_a, MYROW, iarow, NPROW),
nqa0 = numroc(n+icoffa, nb_a, MYCOL, iacol, NPCOL)

```

`indxg2p` and `numroc` are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the function `blacs_gridinfo`.

NOTE

`mod(x, y)` is the integer remainder of x/y .

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by [pxerbla](#).

Output Parameters

a Contains the local pieces of the *m*-by-*n* distributed matrix Q.

work[0] On exit, *work*[0] contains the minimum value of *lwork* required for optimum performance.

info (global)

- = 0: the execution is successful.
- < 0: if the *i*-th argument is an array and the *j*-th entry, indexed *j* - 1, had an illegal value, then *info* = -(*i**100+*j*); if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

*ic , MKL_INT *jc , MKL_INT *descc , double *work , MKL_INT *lwork , MKL_INT *info );
```

Include Files

- `mk1_scalapack.h`

Description

The `p?ormrq` function overwrites the general real m -by- n distributed matrix sub (C) = $C(ic:ic+m-1, jc:jc+n-1)$ with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q * sub(C)$	$sub(C) * Q$
$trans = 'T':$	$Q^T * sub(C)$	$sub(C) * Q^T$

where Q is a real orthogonal distributed matrix defined as the product of k elementary reflectors

$Q = H(1) H(2) \dots H(k)$

as returned by `p?gerqf`. Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

<i>side</i>	(global) ='L': Q or Q^T is applied from the left. ='R': Q or Q^T is applied from the right.
<i>trans</i>	(global) ='N', no transpose, Q is applied. ='T', transpose, Q^T is applied.
<i>m</i>	(global) The number of rows in the distributed matrix $sub(C)$ ($m \geq 0$).
<i>n</i>	(global) The number of columns in the distributed matrix $sub(C)$ ($n \geq 0$).
<i>k</i>	(global) The number of elementary reflectors whose product defines the matrix Q . Constraints: If $side = 'L'$, $m \geq k \geq 0$ If $side = 'R'$, $n \geq k \geq 0$.
<i>a</i>	(local) Pointer into the local memory to an array of size $lld\_a * LOCC(ja+m-1)$ if $side = 'L'$, and $lld\_a * LOCC(ja+n-1)$ if $side = 'R'$. The i -th row of the matrix stored in a must contain the vector that defines the elementary reflector $H(i)$, $ia \leq i \leq ia+k-1$, as returned by <code>p?gerqf</code> in the k rows of its distributed matrix argument $A(ia:ia+k-1, ja:*)$. $A(ia:ia+k-1, ja:*)$ is modified by the function but restored on exit.
<i>ia, ja</i>	(global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively.
<i>desca</i>	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix A .
<i>tau</i>	(local) Array of size $LOCC(ja+k-1)$. Contains the scalar factor $tau[i]$ of elementary reflectors $H(i+1)$ as returned by <code>p?gerqf</code> ($0 \leq i < LOCC(ja+k-1)$). tau is tied to the distributed matrix A .
<i>c</i>	(local) Pointer into the local memory to an array of local size $lld\_c * LOCC(jc+n-1)$. Contains the local pieces of the distributed matrix $sub(C)$ to be factored.
<i>ic, jc</i>	(global) The row and column indices in the global matrix C indicating the first row and the first column of the matrix $sub(C)$, respectively.

<i>desc</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>C</i> .
<i>work</i>	(local) Workspace array of size of <i>lwork</i> .
<i>lwork</i>	(local or global) size of <i>work</i> , must be at least: If <i>side</i> = 'L', $lwork \geq \max((mb\_a * (mb\_a - 1)) / 2, (mpc0 + \max(mqa0 + \text{numroc}(\text{numroc}(n + iroffc, mb\_a, 0, 0, NPROW), mb\_a, 0, 0, lcmp), nqc0)) * mb\_a) + mb\_a * mb\_a)$ else if <i>side</i> = 'R', $lwork \geq \max((mb\_a * (mb\_a - 1)) / 2, (mpc0 + nqc0) * mb\_a) + mb\_a * mb\_a$ end if where $lcmp = lcm / NPROW \text{ with } lcm = ilcm(NPROW, NPCOL),$ $iroffa = \text{mod}(ia - 1, mb\_a),$ $icoffa = \text{mod}(ja - 1, nb\_a),$ $iacol = \text{indxg2p}(ja, nb\_a, MYCOL, csrc\_a, NPCOL),$ $mqa0 = \text{numroc}(n + icoffa, nb\_a, MYCOL, iacol, NPCOL),$ $iroffc = \text{mod}(ic - 1, mb\_c),$ $icoffc = \text{mod}(jc - 1, nb\_c),$ $icrow = \text{indxg2p}(ic, mb\_c, MYROW, rsrc\_c, NPROW),$ $iccol = \text{indxg2p}(jc, nb\_c, MYCOL, csrc\_c, NPCOL),$ $mpc0 = \text{numroc}(m + iroffc, mb\_c, MYROW, icrow, NPROW),$ $nqc0 = \text{numroc}(n + icoffc, nb\_c, MYCOL, iccol, NPCOL),$

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

ilcm, *indxg2p* and *numroc* are ScaLAPACK tool functions; *MYROW*, *MYCOL*, *NPROW* and *NPCOL* can be determined by calling the function *blacs_gridinfo*.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by *pxerbla*.

Output Parameters

<i>c</i>	Overwritten by the product $Q * \text{sub}(C)$, or $Q' * \text{sub}(C)$, or $\text{sub}(C) * Q'$, or $\text{sub}(C) * Q$

`work[0]` On exit `work[0]` contains the minimum value of `lwork` required for optimum performance.

`info` (global)
 = 0: the execution is successful.
 < 0: if the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then `info` = $-(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then `info` = $-i$.

Description

This function overwrites the general complex m -by- n distributed matrix sub (C) = $C(ic:ic+m-1,jc:jc+n-1)$ with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q * sub(C)$	$sub(C) * Q$
$trans = 'C':$	$Q^H * sub(C)$	$sub(C) * Q^H$

where Q is a complex unitary distributed matrix defined as the product of k elementary reflectors

$$Q = H(1)' H(2)' \dots H(k)'$$

as returned by `p?gerqf`. Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

`side` (global)
 = 'L': Q or Q^H is applied from the left.
 = 'R': Q or Q^H is applied from the right.

`trans` (global)
 = 'N', no transpose, Q is applied.

= 'C', conjugate transpose, Q^H is applied.

<i>m</i>	(global) The number of rows in the distributed matrix sub(C) , ($m \geq 0$) .
<i>n</i>	(global) The number of columns in the distributed matrix sub(C), ($n \geq 0$) .
<i>k</i>	(global) The number of elementary reflectors whose product defines the matrix Q. Constraints: If <i>side</i> = 'L', $m \geq k \geq 0$ If <i>side</i> = 'R', $n \geq k \geq 0$.
<i>a</i>	(local) Pointer into the local memory to an array of size $lld\_a * LOCc(ja+m-1)$ if <i>side</i> = 'L', and $lld\_a * LOCc(ja+n-1)$ if <i>side</i> = 'R'. The <i>i</i>-th row of the matrix stored in <i>a</i> must contain the vector that defines the elementary reflector $H(i)$, $ia \leq i \leq ia+k-1$, as returned by p?gerqf in the <i>k</i> rows of its distributed matrix argument $A(ia:ia+k-1, ja:*)$. $A(ia:ia+k-1, ja:*)$ is modified by the function but restored on exit.
<i>ia, ja</i>	(global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix A .
<i>tau</i>	(local) Array of size $LOCc(ja+k-1)$. Contains the scalar factor $\tau[i]$ of elementary reflectors $H(i+1)$ as returned by p?gerqf ($0 \leq i < LOCc(ja+k-1)$). <i>tau</i> is tied to the distributed matrix A.
<i>c</i>	(local) Pointer into the local memory to an array of local size $lld\_c * LOCc(jc+n-1)$. Contains the local pieces of the distributed matrix sub(C) to be factored.
<i>ic, jc</i>	(global) The row and column indices in the global matrix C indicating the first row and the first column of the submatrix C , respectively.
<i>descc</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix C .
<i>work</i>	(local) Workspace array of size of <i>lwork</i>.
<i>lwork</i>	(local or global) size of <i>work</i>, must be at least: If <i>side</i> = 'L', $lwork \geq \max((mb\_a * (mb\_a - 1)) / 2, (mpc0 + \max(mqa0 + \text{numroc}(\text{numroc}(n + iroffc, mb\_a, 0, 0, NPROW), mb\_a, 0, 0, lcmp), nqc0)) * mb\_a) + mb\_a * mb\_a)$ else if <i>side</i> = 'R',

```

lwork ≥ max((mb_a*(mb_a-1))/2, (mpc0 + nqc0)*mb_a) + mb_a*mb_a
end if
where
lcmp = lcm/NPROW with lcm = ilcm(NPROW, NPCOL),
iroffa = mod(ia-1, mb_a),
icoffa = mod(ja-1, nb_a),
iacol = indxg2p(ja, nb_a, MYCOL, csrc_a, NPCOL),
mqa0 = numroc(m+icoffa, nb_a, MYCOL, iacol, NPCOL),
iroffc = mod(ic-1, mb_c),
icoffc = mod(jc-1, nb_c),
icrow = indxg2p(ic, mb_c, MYROW, rsrc_c, NPROW),
iccol = indxg2p(jc, nb_c, MYCOL, csrc_c, NPCOL),
mpc0 = numroc(m+iroffc, mb_c, MYROW, icrow, NPROW),
nqc0 = numroc(n+icoffc, nb_c, MYCOL, iccol, NPCOL),

```

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

`ilcm`, `indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the function `blacs_gridinfo`.

If `lwork` = -1, then `lwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

<code>c</code>	Overwritten by the product $Q * \text{sub}(C)$ or $Q' * \text{sub}(C)$, or $\text{sub}(C) * Q'$, or $\text{sub}(C) * Q$
<code>work[0]</code>	On exit <code>work[0]</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) = 0: the execution is successful. < 0: if the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then <code>info</code> = $-(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then <code>info</code> = $-i$.

*info );
```

Include Files

- mkl_scalapack.h

Description

The p?tzrzf function reduces the m -by- n ($m \leq n$) real/complex upper trapezoidal matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$ to upper triangular form by means of orthogonal/unitary transformations. The upper trapezoidal matrix A is factored as

$$A = (R \ 0) * Z,$$

where Z is an n -by- n orthogonal/unitary matrix and R is an m -by- m upper triangular matrix.

Input Parameters

m	(global) The number of rows in the matrix $\text{sub}(A)$; ($m \geq 0$).
n	(global) The number of columns in the matrix $\text{sub}(A)$ ($n \geq 0$).
a	(local) Pointer into the local memory to an array of size $lld\_a * LOCc(ja+n-1)$. Contains the local pieces of the m -by- n distributed matrix $\text{sub}(A)$ to be factored.
ia, ja	(global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively.
$desca$	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix A .
$work$	(local) Workspace array of size of $lwork$.
$lwork$	(local or global) size of $work$, must be at least $lwork \geq mb\_a * (mp0 + nq0 + mb\_a)$, where $iroff = \text{mod}(ia-1, mb\_a)$,

```

icoff = mod(ja-1, nb_a),
iarow = indxg2p(ia, mb_a, MYROW, rsrc_a, NPROW),
iacol = indxg2p(ja, nb_a, MYCOL, csrc_a, NPCOL),
mp0 = numroc (m+iroff, mb_a, MYROW, iarow, NPROW),
nq0 = numroc (n+icoff, nb_a, MYCOL, iacol, NPCOL)

```

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

`indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the function `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

<i>a</i>	On exit, the leading m -by- m upper triangular part of <code>sub(A)</code> contains the upper triangular matrix R , and elements $m+1$ to n of the first m rows of <code>sub(A)</code> , with the array <i>tau</i> , represent the orthogonal/unitary matrix Z as a product of m elementary reflectors.
<i>work</i> [0]	On exit <i>work</i> [0] contains the minimum value of <code>lwork</code> required for optimum performance.
<i>tau</i>	(local) Array of size <code>LOCr(ia+m-1)</code> . Contains the scalar factor of elementary reflectors. <i>tau</i> is tied to the distributed matrix A .
<i>info</i>	(global) = 0: the execution is successful. < 0: if the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then <i>info</i> = $-(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then <i>info</i> = $-i$.

Application Notes

The factorization is obtained by the Householder's method. The k -th transformation matrix, $Z(k)$, which is or whose conjugate transpose is used to introduce zeros into the $(m - k + 1)$ -th row of `sub(A)`, is given in the form

$$\begin{pmatrix} 1 & & & & & & & \\ & \ddots & & & & & & \\ & & \ddots & & & & & \\ & & & \ddots & & & & \\ & & & & \ddots & & & \\ & & & & & \ddots & & \\ & & & & & & \ddots & \\ & & & & & & & 1 \end{pmatrix} \begin{pmatrix} & & & & & & & \\ & & & & & & & \\ & & & & & & & \\ & & & & & & & \\ & & & & & & & \\ & & & & & & & \\ & & & & & & & \\ & & & & & & & \end{pmatrix}$$

where

$$T(k) = i - \tau u(k) u(k)',$$

$$\begin{bmatrix} 1 & & & \\ & \ddots & & \\ & & \ddots & \\ & & & 1 \end{bmatrix}$$

τ is a scalar and $Z(k)$ is an $(n - m)$ element vector. τ and $Z(k)$ are chosen to annihilate the elements of the k -th row of sub(A). The scalar τ is returned in the k -th element of τ , indexed $k-1$, and the vector $u(k)$ in the k -th row of sub(A), such that the elements of $Z(k)$ are in $a(k, m + 1), \dots, a(k, n)$. The elements of R are returned in the upper triangular part of sub(A). Z is given by

$$Z = Z(1) * Z(2) * \dots * Z(m).$$

Description

This function overwrites the general real m -by- n distributed matrix sub(C) = $C(ic:ic+m-1, jc:jc+n-1)$ with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q * sub(C)$	$sub(C) * Q$
$trans = 'T':$	$Q^T * sub(C)$	$sub(C) * Q^T$

where Q is a real orthogonal distributed matrix defined as the product of k elementary reflectors

$$Q = H(1) H(2) \dots H(k)$$

as returned by p?tzzrf. Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

<i>side</i>	(global) = 'L': Q or Q^T is applied from the left. = 'R': Q or Q^T is applied from the right.
<i>trans</i>	(global) = 'N', no transpose, Q is applied. = 'T', transpose, Q^T is applied.
<i>m</i>	(global) The number of rows in the distributed matrix $\text{sub}(C)$ ($m \geq 0$).
<i>n</i>	(global) The number of columns in the distributed matrix $\text{sub}(C)$ ($n \geq 0$).
<i>k</i>	(global) The number of elementary reflectors whose product defines the matrix Q. Constraints: If <i>side</i> = 'L', $m \geq k \geq 0$ If <i>side</i> = 'R', $n \geq k \geq 0$.
<i>l</i>	(global) The columns of the distributed matrix $\text{sub}(A)$ containing the meaningful part of the Householder reflectors. If <i>side</i> = 'L', $m \geq l \geq 0$ If <i>side</i> = 'R', $n \geq l \geq 0$.
<i>a</i>	(local) Pointer into the local memory to an array of size $lld\_a * LOCC(ja+m-1)$ if <i>side</i> = 'L', and $lld\_a * LOCC(ja+n-1)$ if <i>side</i> = 'R', where $lld\_a \geq \max(1, LOCr(ia+k-1))$. The <i>i</i>-th row of the matrix stored in <i>a</i> must contain the vector that defines the elementary reflector $H(i)$, $ia \leq i \leq ia+k-1$, as returned by <code>p?tzrzf</code> in the <i>k</i> rows of its distributed matrix argument $A(ia:ia+k-1, ja:*)$. $A(ia:ia+k-1, ja:*)$ is modified by the function but restored on exit.
<i>ia, ja</i>	(global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix A .
<i>tau</i>	(local) Array of size $LOCC(ia+k-1)$. Contains the scalar factor $\tau[i]$ of elementary reflectors $H(i+1)$ as returned by <code>p?tzrzf</code> ($0 \leq i < LOCC(ia+k-1)$). <i>tau</i> is tied to the distributed matrix A.
<i>c</i>	(local) Pointer into the local memory to an array of local size $lld\_c * LOCC(jc+n-1)$.

Contains the local pieces of the distributed matrix sub(*C*) to be factored.

ic, jc (global) The row and column indices in the global matrix *C* indicating the first row and the first column of the submatrix *C*, respectively.

desc (global and local) array of size *dlen_*. The array descriptor for the distributed matrix *C*.

work (local)
Workspace array of size of *lwork*.

lwork (local or global) size of *work*, must be at least:

```

If side = 'L',
    lwork ≥ max((mb_a*(mb_a-1))/2, (mpc0 + max(mqa0 +
numroc(numroc(n+iroffc, mb_a, 0, 0, NPROW), mb_a, 0, 0,
lcmp), nqc0))*mb_a + mb_a*mb_a
else if side = 'R',
    lwork ≥ max((mb_a*(mb_a-1))/2, (mpc0 + nqc0)*mb_a + mb_a*mb_a
end if
where
lcmp = lcm/NPROW with lcm = ilcm (NPROW, NPCOL),
iroffa = mod(ia-1, mb_a), icoffa = mod(ja-1, nb_a),
iacol = indxg2p(ja, nb_a, MYCOL, csrc_a, NPCOL),
mqa0 = numroc(n+icoffa, nb_a, MYCOL, iacol, NPCOL),
iroffc = mod(ic-1, mb_c),
icoffc = mod(jc-1, nb_c),
icrow = indxg2p(ic, mb_c, MYROW, rsrc_c, NPROW),
iccol = indxg2p(jc, nb_c, MYCOL, csrc_c, NPCOL),
mpc0 = numroc(m+iroffc, mb_c, MYROW, icrow, NPROW),
nqc0 = numroc(n+icoffc, nb_c, MYCOL, iccol, NPCOL),

```

NOTE

mod(*x*, *y*) is the integer remainder of *x*/*y*.

ilcm, indxg2p and numroc are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the function blacs_gridinfo.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by p_{xerbla}.

Output Parameters

<code>c</code>	Overwritten by the product $Q*\text{sub}(C)$, or $Q'*\text{sub}(C)$, or $\text{sub}(C)*Q'$, or $\text{sub}(C)*Q$
<code>work[0]</code>	On exit <code>work[0]</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) = 0: the execution is successful. < 0: if the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then <code>info</code> = $-(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then <code>info</code> = $-i$.

Description

This function overwrites the general complex m -by- n distributed matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q*\text{sub}(C)$	$\text{sub}(C)*Q$
$trans = 'C':$	$Q^H*\text{sub}(C)$	$\text{sub}(C)*Q^H$

where Q is a complex unitary distributed matrix defined as the product of k elementary reflectors

$$Q = H(1)' H(2)' \dots H(k)'$$

as returned by `pctzrzf/pztzrzf`. Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

<code>side</code>	(global)

= 'L': Q or Q^H is applied from the left.

= 'R': Q or Q^H is applied from the right.

trans

(global)

= 'N', no transpose, Q is applied.

= 'C', conjugate transpose, Q^H is applied.

m

(global) The number of rows in the distributed matrix $\text{sub}(C)$, ($m \geq 0$).

n

(global) The number of columns in the distributed matrix $\text{sub}(C)$, ($n \geq 0$).

k

(global) The number of elementary reflectors whose product defines the matrix Q . Constraints:

If *side* = 'L', $m \geq k \geq 0$

If *side* = 'R', $n \geq k \geq 0$.

l

(global) The columns of the distributed matrix $\text{sub}(A)$ containing the meaningful part of the Householder reflectors.

If *side* = 'L', $m \geq l \geq 0$

If *side* = 'R', $n \geq l \geq 0$.

a

(local)

Pointer into the local memory to an array of size $lld\_a * LOCC(ja+m-1)$ if *side* = 'L', and $lld\_a * LOCC(ja+n-1)$ if *side* = 'R', where $lld\_a \geq \max(1, LOCr(ja+k-1))$. The *i*-th row of the matrix stored in *a* must contain the vector that defines the elementary reflector $H(i)$, $ia \leq i \leq ia+k-1$, as returned by `p?gerqf` in the *k* rows of its distributed matrix argument $A(ia:ia+k-1, ja:*)$. $A(ia:ia+k-1, ja:*)$ is modified by the function but restored on exit.

ia, ja

(global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively.

desca

(global and local) array of size *dlen_*. The array descriptor for the distributed matrix A .

tau

(local)

Array of size $LOCC(ia+k-1)$.

Contains the scalar factor $\tau[i]$ of elementary reflectors $H(i+1)$ as returned by `p?gerqf` ($0 \leq i < LOCC(ia+k-1)$). *tau* is tied to the distributed matrix A .

c

(local)

Pointer into the local memory to an array of local size $lld\_c * LOCC(jc+n-1)$.

Contains the local pieces of the distributed matrix $\text{sub}(C)$ to be factored.

ic, jc

(global) The row and column indices in the global matrix C indicating the first row and the first column of the submatrix C , respectively.

<i>desc</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>C</i> .
<i>work</i>	(local) Workspace array of size <i>lwork</i> .
<i>lwork</i>	(local or global) size of <i>work</i> , must be at least: If <i>side</i> = 'L', $lwork \geq \max((mb\_a * (mb\_a - 1)) / 2, (mpc0 + \max(mqa0 + \text{numroc}(\text{numroc}(n + iroffc, mb\_a, 0, 0, NPROW), mb\_a, 0, 0, lcmp), nqc0)) * mb\_a) + mb\_a * mb\_a)$ else if <i>side</i> = 'R', $lwork \geq \max((mb\_a * (mb\_a - 1)) / 2, (mpc0 + nqc0) * mb\_a) + mb\_a * mb\_a$ end if where $lcmp = lcm / NPROW \text{ with } lcm = ilcm(NPROW, NPCOL),$ $iroffa = \text{mod}(ia - 1, mb\_a),$ $icoffa = \text{mod}(ja - 1, nb\_a),$ $iacol = \text{indxg2p}(ja, nb\_a, MYCOL, csrc\_a, NPCOL),$ $mqa0 = \text{numroc}(m + icoffa, nb\_a, MYCOL, iacol, NPCOL),$ $iroffc = \text{mod}(ic - 1, mb\_c),$ $icoffc = \text{mod}(jc - 1, nb\_c),$ $icrow = \text{indxg2p}(ic, mb\_c, MYROW, rsrc\_c, NPROW),$ $iccol = \text{indxg2p}(jc, nb\_c, MYCOL, csrc\_c, NPCOL),$ $mpc0 = \text{numroc}(m + iroffc, mb\_c, MYROW, icrow, NPROW),$ $nqc0 = \text{numroc}(n + icoffc, nb\_c, MYCOL, iccol, NPCOL),$

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

ilcm, *indxg2p* and *numroc* are ScaLAPACK tool functions; *MYROW*, *MYCOL*, *NPROW* and *NPCOL* can be determined by calling the function *blacs_gridinfo*.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by *p_xerbla*.

Output Parameters

<i>c</i>	Overwritten by the product $Q * \text{sub}(C)$, or $Q' * \text{sub}(C)$, or $\text{sub}(C) * Q'$, or $\text{sub}(C) * Q$

<code>work[0]</code>	On exit <code>work[0]</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) = 0: the execution is successful. < 0: if the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then <code>info</code> = $-(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then <code>info</code> = $-i$.

Include Files

- `mkl_scalapack.h`

Description

The `p?ggqrf` function forms the generalized QR factorization of an n -by- m matrix

$\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+m-1)$

and an n -by- p matrix

$\text{sub}(B) = B(\text{ib}:\text{ib}+n-1, \text{jb}:\text{jb}+p-1):$

as

$\text{sub}(A) = Q * R, \text{sub}(B) = Q * T * Z,$

where Q is an n -by- n orthogonal/unitary matrix, Z is a p -by- p orthogonal/unitary matrix, and R and T assume one of the forms:

If $n \geq m$

$$R = \begin{pmatrix} R_{11} & & \\ & 0 & \\ & & \end{pmatrix} \begin{matrix} m \\ n - m \\ m \end{matrix}$$

or if $n < m$

$$R = \begin{pmatrix} R_{11} & R_{12} \\ & \end{pmatrix} \begin{matrix} n \\ n & m - n \end{matrix}$$

where R_{11} is upper triangular, and

$$T = \begin{pmatrix} 0 & T_{12} \\ & \end{pmatrix} \begin{matrix} n, \text{ if } n \leq p, \\ p - n & n \end{matrix}$$

$$\text{or } T = \begin{pmatrix} T_{11} \\ T_{21} \end{pmatrix} \begin{pmatrix} n - p \\ p \end{pmatrix}, \text{ if } n > p,$$

p

where T_{12} or T_{21} is an upper triangular matrix.

In particular, if $\text{sub}(B)$ is square and nonsingular, the GQR factorization of $\text{sub}(A)$ and $\text{sub}(B)$ implicitly gives the QR factorization of $\text{inv}(\text{sub}(B)) * \text{sub}(A)$:

$$\text{inv}(\text{sub}(B)) * \text{sub}(A) = Z^H * (\text{inv}(T) * R)$$

Input Parameters

n	(global) The number of rows in the distributed matrices $\text{sub}(A)$ and $\text{sub}(B)$ ($n \geq 0$).
m	(global) The number of columns in the distributed matrix $\text{sub}(A)$ ($m \geq 0$).
p	The number of columns in the distributed matrix $\text{sub}(B)$ ($p \geq 0$).
a	(local) Pointer into the local memory to an array of size $lld\_a * LOCc(ja+m-1)$. Contains the local pieces of the n -by- m matrix $\text{sub}(A)$ to be factored.
ia, ja	(global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively.

<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .
<i>b</i>	(local) Pointer into the local memory to an array of size $lld\_b * LOCc(jb+p-1)$. Contains the local pieces of the <i>n</i> -by- <i>p</i> matrix sub(<i>B</i>) to be factored.
<i>ib, jb</i>	(global) The row and column indices in the global matrix <i>B</i> indicating the first row and the first column of the submatrix <i>B</i> , respectively.
<i>descb</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>B</i> .
<i>work</i>	(local) Workspace array of size of <i>lwork</i> .
<i>lwork</i>	(local or global) Size of <i>work</i> , must be at least

$$lwork \geq \max(nb\_a * (npa0 + mqa0 + nb\_a), \max((nb\_a * (nb\_a - 1)) / 2, (pqb0 + npb0) * nb\_a) + nb\_a * nb\_a, mb\_b * (npb0 + pqb0 + mb\_b)),$$

where

```

iroffa = mod(ia-1, mb_a),
icoffa = mod(ja-1, nb_a),
iarow = indxg2p(ia, mb_a, MYROW, rsrc_a, NPROW),
iacol = indxg2p(ja, nb_a, MYCOL, csrc_a, NPCOL),
npa0 = numroc(n+iroffa, mb_a, MYROW, iarow, NPROW),
mqa0 = numroc(m+icoffa, nb_a, MYCOL, iacol, NPCOL)
iroffb = mod(ib-1, mb_b),
icoffb = mod(jb-1, nb_b),
ibrow = indxg2p(ib, mb_b, MYROW, rsrc_b, NPROW),
ibcol = indxg2p(jb, nb_b, MYCOL, csrc_b, NPCOL),
npb0 = numroc(n+iroffa, mb_b, MYROW, ibrow, NPROW),
pqb0 = numroc(m+icoffb, nb_b, MYCOL, ibcol, NPCOL)

```

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

and `numroc`, `indxg2p` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the function `blacs_gridinfo`.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by [pxerbla](#).

Output Parameters

<i>a</i>	On exit, the elements on and above the diagonal of sub (A) contain the $\min(n, m)$ -by- m upper trapezoidal matrix R (R is upper triangular if $n \geq m$); the elements below the diagonal, with the array <i>taua</i> , represent the orthogonal/unitary matrix Q as a product of $\min(n, m)$ elementary reflectors. (See Application Notes below).
<i>taua</i> , <i>taub</i>	(local) Arrays of size $LOCc(ja+\min(n, m)-1)$ for <i>taua</i> and $LOCr(ib+n-1)$ for <i>taub</i> . The array <i>taua</i> contains the scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix Q . <i>taua</i> is tied to the distributed matrix A . (See Application Notes below). The array <i>taub</i> contains the scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix Z . <i>taub</i> is tied to the distributed matrix B . (See Application Notes below).
<i>work</i> [0]	On exit <i>work</i> [0] contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	(global) = 0: the execution is successful. < 0: if the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

Application Notes

The matrix Q is represented as a product of elementary reflectors

$$Q = H(j_a) * H(j_a+1) * \dots * H(j_a+k-1),$$

where $k = \min(n, m)$.

Each $H(i)$ has the form

$$H(i) = I - \tau_{ua} * v * v'$$

where τ_{ua} is a real/complex scalar, and v is a real/complex vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:n)$ is stored on exit in $A(ia+i:ia+n-1, ja+i-1)$, and τ_{ua} in $\tau_{ua}[ja+i-2]$. To form Q explicitly, use ScaLAPACK function [p?orgqr/p?ungqr](#). To use Q to update another matrix, use ScaLAPACK function [p?ormqr/p?unmqr](#).

The matrix Z is represented as a product of elementary reflectors

$$Z = H(i_b) * H(i_b+1) * \dots * H(i_b+k-1), \text{ where } k = \min(n, p).$$

Each $H(i)$ has the form

$$H(i) = I - \tau_{ub} * v * v'$$

where τ_{ub} is a real/complex scalar, and v is a real/complex vector with $v(p-k+i+1:p) = 0$ and $v(p-k+i) = 1$; $v(1:p-k+i-1)$ is stored on exit in $B(ib+n-k+i-1, jb:jb+p-k+i-2)$, and τ_{ub} in $\tau_{ub}[ib+n-k+i-2]$. To form Z explicitly, use ScaLAPACK function [p?orgqr/p?ungqr](#). To use Z to update another matrix, use ScaLAPACK function [p?ormqr/p?unmqr](#).

```

Include Files

- mkl_scalapack.h

Description

The p?ggrqf function forms the generalized *RQ* factorization of an *m*-by-*n* matrix $\text{sub}(A) = A(\text{ia}:\text{ia}+m-1, \text{ja}:\text{ja}+n-1)$ and a *p*-by-*n* matrix $\text{sub}(B) = B(\text{ib}:\text{ib}+p-1, \text{jb}:\text{jb}+n-1)$:

$\text{sub}(A) = R*Q$, $\text{sub}(B) = Z*T*Q$,

where *Q* is an *n*-by-*n* orthogonal/unitary matrix, *Z* is a *p*-by-*p* orthogonal/unitary matrix, and *R* and *T* assume one of the forms:

$$R = \begin{pmatrix} 0 & R_{12} \\ R_{21} & R_{22} \end{pmatrix}, \text{ if } m \leq n,$$

or

$$R = \begin{pmatrix} R_{11} & R_{12} \\ R_{21} & R_{22} \end{pmatrix}, \text{ if } m > n$$

where R_{11} or R_{21} is upper triangular, and

$$T = \begin{pmatrix} T_{11} & & \\ & & \\ 0 & & \end{pmatrix} \begin{matrix} n \\ p-n \\ n \end{matrix}, \text{ if } p \geq n$$

or

$$\begin{pmatrix} & & & & & & \\ & & & & & & \\ & & & & & & \\ & & & & & & \\ & & & & & & \\ & & & & & & \\ & & & & & & \end{pmatrix} \begin{pmatrix} & & & & & & \\ & & & & & & \\ & & & & & & \\ & & & & & & \\ & & & & & & \\ & & & & & & \\ & & & & & & \end{pmatrix}$$

where T_{11} is upper triangular.

In particular, if $\text{sub}(B)$ is square and nonsingular, the *GRQ* factorization of $\text{sub}(A)$ and $\text{sub}(B)$ implicitly gives the *RQ* factorization of $\text{sub}(A) * \text{inv}(\text{sub}(B))$:

$$\text{sub}(A) * \text{inv}(\text{sub}(B)) = (R * \text{inv}(T)) * Z'$$

where $\text{inv}(\text{sub}(B))$ denotes the inverse of the matrix $\text{sub}(B)$, and Z' denotes the transpose (conjugate transpose) of matrix Z .

Input Parameters

m	(global) The number of rows in the distributed matrices $\text{sub}(A)$ ($m \geq 0$).
p	The number of rows in the distributed matrix $\text{sub}(B)$ ($p \geq 0$).
n	(global) The number of columns in the distributed matrices $\text{sub}(A)$ and $\text{sub}(B)$ ($n \geq 0$).
a	(local) Pointer into the local memory to an array of size $lld\_a * LOCc(ja+n-1)$. Contains the local pieces of the m -by- n distributed matrix $\text{sub}(A)$ to be factored.
ia, ja	(global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively.
$desca$	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix A .
b	(local) Pointer into the local memory to an array of size $lld\_b * LOCc(jb+n-1)$. Contains the local pieces of the p -by- n matrix $\text{sub}(B)$ to be factored.
ib, jb	(global) The row and column indices in the global matrix B indicating the first row and the first column of the submatrix B , respectively.
$descb$	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix B .
$work$	(local)

lwork

Workspace array of size of *lwork*.

(local or global)

Size of *work*, must be at least $lwork \geq \max(mb\_a * (mpa0 + nqa0 + mb\_a), \max((mb\_a * (mb\_a - 1)) / 2, (ppb0 + nqb0) * mb\_a) + mb\_a * mb\_a, nb\_b * (ppb0 + nqb0 + nb\_b))$, where

```
iroffa = mod(ia-1, mb_a),
icoffa = mod(ja-1, nb_a),
iarow = indxg2p(ia, mb_a, MYROW, rsrc_a, NPROW),
iacol = indxg2p(ja, nb_a, MYCOL, csrc_a, NPCOL),
mpa0 = numroc (m+iroffa, mb_a, MYROW, iarow, NPROW),
nqa0 = numroc (m+icoffa, nb_a, MYCOL, iacol, NPCOL)
iroffb = mod(ib-1, mb_b),
icoffb = mod(jb-1, nb_b),
ibrow = indxg2p(ib, mb_b, MYROW, rsrc_b, NPROW),
ibcol = indxg2p(jb, nb_b, MYCOL, csrc_b, NPCOL),
ppb0 = numroc (p+iroffb, mb_b, MYROW, ibrow, NPROW),
nqb0 = numroc (n+icoffb, nb_b, MYCOL, ibcol, NPCOL)
```

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

and *numroc*, *indxg2p* are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the function *blacs_gridinfo*.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by *pxerbla*.

Output Parameters

a

On exit, if $m \leq n$, the upper triangle of $A(ia:ia+m-1, ja+n-m:ja+n-1)$ contains the m -by- m upper triangular matrix R ; if $m \geq n$, the elements on and above the $(m-n)$ -th subdiagonal contain the m -by- n upper trapezoidal matrix R ; the remaining elements, with the array *taua*, represent the orthogonal/unitary matrix Q as a product of $\min(n, m)$ elementary reflectors (see *Application Notes* below).

taua, *taub*

(local)

Arrays of size $LOCr(ia+m-1)$ for *taua* and $LOCc(jb+\min(p, n)-1)$ for *taub*.

The array *taua* contains the scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix Q . *taua* is tied to the distributed matrix A . (See *Application Notes* below).

The array *taub* contains the scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix *Z*. *taub* is tied to the distributed matrix *B*. (See *Application Notes* below).

work[0]

On exit *work*[0] contains the minimum value of *lwork* required for optimum performance.

info

(global)

= 0: the execution is successful.

< 0: if the *i*-th argument is an array and the *j*-th entry, indexed *j* - 1, had an illegal value, then *info* = -(*i**100+*j*); if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

Application Notes

The matrix *Q* is represented as a product of elementary reflectors

$$Q = H(i_a) * H(i_a+1) * \dots * H(i_a+k-1),$$

where $k = \min(m, n)$.

Each *H*(*i*) has the form

$$H(i) = I - \tau_a * v * v'$$

where *taua* is a real/complex scalar, and *v* is a real/complex vector with $v(n-k+i+1:n) = 0$ and $v(n-k+i) = 1$; $v(1:n-k+i-1)$ is stored on exit in $A(i_a+m-k+i-1, j_a:j_a+n-k+i-2)$, and *taua* in $\tau_a[i_a+m-k+i-2]$. To form *Q* explicitly, use ScaLAPACK function [p?orgqr/p?ungqr](#). To use *Q* to update another matrix, use ScaLAPACK function [p?ormqr/p?unmqr](#).

The matrix *Z* is represented as a product of elementary reflectors

$$Z = H(j_b) * H(j_b+1) * \dots * H(j_b+k-1), \text{ where } k = \min(p, n).$$

Each *H*(*i*) has the form

$$H(i) = I - \tau_b * v * v'$$

where *taub* is a real/complex scalar, and *v* is a real/complex vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:p)$ is stored on exit in $B(i_b+i:i_b+p-1, j_b+i-1)$, and *taub* in $\tau_b[j_b+i-2]$. To form *Z* explicitly, use ScaLAPACK function [p?orgqr/p?ungqr](#). To use *Z* to update another matrix, use ScaLAPACK function [p?ormqr/p?unmqr](#).

See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

Symmetric Eigenproblems

To solve a symmetric eigenproblem with ScaLAPACK, you usually need to reduce the matrix to real tridiagonal form *T* and then find the eigenvalues and eigenvectors of the tridiagonal matrix *T*. ScaLAPACK includes routines for reducing the matrix to a tridiagonal form by an orthogonal (or unitary) similarity transformation $A = Q T Q^H$ as well as for solving tridiagonal symmetric eigenvalue problems. These routines are listed in [Table "Computational Routines for Solving Symmetric Eigenproblems"](#).

There are different routines for symmetric eigenproblems, depending on whether you need eigenvalues only or eigenvectors as well, and on the algorithm used (either the *QTQ* algorithm, or bisection followed by inverse iteration).

Computational Routines for Solving Symmetric Eigenproblems

Operation	Dense symmetric/ Hermitian matrix	Orthogonal/unitary matrix	Symmetric tridiagonal matrix
Reduce to tridiagonal form $A = QTQ^H$	p?sytrd/p?hetrd		
Multiply matrix after reduction		p?ormtr/p?unmtr	
Find all eigenvalues and eigenvectors of a tridiagonal matrix T by a QTQ method			steqr2*
Find selected eigenvalues of a tridiagonal matrix T via bisection			p?stebz
Find selected eigenvectors of a tridiagonal matrix T by inverse iteration			p?stein

* This routine is described as part of auxiliary ScaLAPACK routines.

[p?sytrd](#)

Reduces a symmetric matrix to real symmetric tridiagonal form by an orthogonal similarity transformation.

Syntax

```
void pssytrd (char *uplo , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *d , float *e , float *tau , float *work , MKL_INT *lwork , MKL_INT *info );
```

```
void pdsytrd (char *uplo , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *d , double *e , double *tau , double *work , MKL_INT *lwork , MKL_INT *info );
```

Include Files

- `mkl_scalapack.h`

Description

The `p?sytrd` function reduces a real symmetric matrix $\text{sub}(A)$ to symmetric tridiagonal form T by an orthogonal similarity transformation:

$$Q^* \text{sub}(A) Q = T,$$

where $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$.

Input Parameters

<code>uplo</code>	(global) Specifies whether the upper or lower triangular part of the symmetric matrix $\text{sub}(A)$ is stored: If <code>uplo</code> = 'U', upper triangular If <code>uplo</code> = 'L', lower triangular
<code>n</code>	(global) The order of the distributed matrix $\text{sub}(A)$ ($n \geq 0$).
<code>a</code>	(local)

Pointer into the local memory to an array of size $lld\_a * LOCc(ja+n-1)$. On entry, this array contains the local pieces of the symmetric distributed matrix $sub(A)$.

If $uplo = 'U'$, the leading n -by- n upper triangular part of $sub(A)$ contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced.

If $uplo = 'L'$, the leading n -by- n lower triangular part of $sub(A)$ contains the lower triangular part of the matrix, and its strictly upper triangular part is not referenced. See *Application Notes* below.

ia, ja

(global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively.

desca

(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix A .

work

(local)

Workspace array of size $lwork$.

lwork

(local or global) size of $work$, must be at least:

$lwork \geq \max(NB * (np + 1), 3 * NB),$

where $NB = mb\_a = nb\_a,$

$np = \text{numroc}(n, NB, MYROW, iarow, NPROW),$

$iarow = \text{indxg2p}(ia, NB, MYROW, rsrc\_a, NPROW).$

indxg2p and numroc are ScaLAPACK tool functions; $MYROW$, $MYCOL$, $NPROW$ and $NPCOL$ can be determined by calling the function `blacs_gridinfo`.

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `p_xerbla`.

Output Parameters

a

On exit, if $uplo = 'U'$, the diagonal and first superdiagonal of $sub(A)$ are overwritten by the corresponding elements of the tridiagonal matrix T , and the elements above the first superdiagonal, with the array τ , represent the orthogonal matrix Q as a product of elementary reflectors; if $uplo = 'L'$, the diagonal and first subdiagonal of $sub(A)$ are overwritten by the corresponding elements of the tridiagonal matrix T , and the elements below the first subdiagonal, with the array τ , represent the orthogonal matrix Q as a product of elementary reflectors. See *Application Notes* below.

d

(local)

Arrays of size $LOCc(ja+n-1)$. The diagonal elements of the tridiagonal matrix T :

$d[i] = A(i+1, i+1), 0 \leq i < LOCc(ja+n-1).$

d is tied to the distributed matrix A .

e

(local)

Arrays of size $LOCc(ja+n-1)$ if $uplo = 'U'$, $LOCc(ja+n-2)$ otherwise.

The off-diagonal elements of the tridiagonal matrix T :

$e[i] = A(i+1, i+2)$, $0 \leq i < LOCc(ja+n-1)$ if $uplo = 'U'$,

$e[i] = A(i+2, i+1)$ if $uplo = 'L'$.

e is tied to the distributed matrix A .

tau

(local)

Arrays of size $LOCc(ja+n-1)$. This array contains the scalar factors of the elementary reflectors. *tau* is tied to the distributed matrix A .

work[0]

On exit *work*[0] contains the minimum value of *lwork* required for optimum performance.

info

(global)

= 0: the execution is successful.

< 0: if the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

Application Notes

If $uplo = 'U'$, the matrix Q is represented as a product of elementary reflectors

$Q = H(n-1) \dots H(2) H(1)$.

Each $H(i)$ has the form

$H(i) = I - \tau * v * v'$,

where τ is a real scalar, and v is a real vector with $v(i+1:n) = 0$ and $v(i) = 1$; $v(1:i-1)$ is stored on exit in $A(ia:ia+i-2, ja+i)$, and τ in $\tau[ja+i-2]$.

If $uplo = 'L'$, the matrix Q is represented as a product of elementary reflectors

$Q = H(1) H(2) \dots H(n-1)$.

Each $H(i)$ has the form

$H(i) = I - \tau * v * v'$,

where τ is a real scalar, and v is a real vector with $v(1:i) = 0$ and $v(i+1) = 1$; $v(i+2:n)$ is stored on exit in $A(ia+i+1:ia+n-1, ja+i-1)$, and τ in $\tau[ja+i-2]$.

The contents of $\text{sub}(A)$ on exit are illustrated by the following examples with $n = 5$:

If $uplo = 'U'$:

If `uplo = 'L'`:

$$\begin{array}{c} \begin{array}{c} \vdots \\ \vdots \\ \vdots \\ \vdots \\ \vdots \end{array} \begin{array}{c} \vdots \\ \vdots \\ \vdots \\ \vdots \\ \vdots \end{array} \\ \begin{array}{c} \vdots \\ \vdots \\ \vdots \\ \vdots \\ \vdots \end{array} \end{array}$$

where d and e denote diagonal and off-diagonal elements of T , and v_i denotes an element of the vector defining $H(i)$.

See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

p?ormtr

Multiplies a general matrix by the orthogonal transformation matrix from a reduction to tridiagonal form determined by p?sytrd.

Syntax

```
void psormtr (char *side , char *uplo , char *trans , MKL_INT *m , MKL_INT *n , float
*a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *tau , float *c , MKL_INT
*ic , MKL_INT *jc , MKL_INT *descc , float *work , MKL_INT *lwork , MKL_INT *info );

void pdormtr (char *side , char *uplo , char *trans , MKL_INT *m , MKL_INT *n , double
*a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *tau , double *c , MKL_INT
*ic , MKL_INT *jc , MKL_INT *descc , double *work , MKL_INT *lwork , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

This function overwrites the general real distributed m -by- n matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q * \text{sub}(C)$	$\text{sub}(C) * Q$
$trans = 'T':$	$Q^T * \text{sub}(C)$	$\text{sub}(C) * Q^T$

where Q is a real orthogonal distributed matrix of order nq , with $nq = m$ if $side = 'L'$ and $nq = n$ if $side = 'R'$.

Q is defined as the product of nq elementary reflectors, as returned by [p?sytrd](#).

If `uplo = 'U'`, $Q = H(nq-1) \dots H(2) H(1)$;

If `uplo = 'L'`, $Q = H(1) H(2) \dots H(nq-1)$.

Input Parameters

<i>side</i>	(global) = 'L': Q or Q^T is applied from the left. = 'R': Q or Q^T is applied from the right.
<i>trans</i>	(global) = 'N', no transpose, Q is applied. = 'T', transpose, Q^T is applied.
<i>uplo</i>	(global) = 'U': Upper triangle of $A(ia:*, ja:*)$ contains elementary reflectors from <code>p?sytrd</code>; = 'L': Lower triangle of $A(ia:*, ja:*)$ contains elementary reflectors from <code>p?sytrd</code>
<i>m</i>	(global) The number of rows in the distributed matrix <code>sub(C)</code> ($m \geq 0$).
<i>n</i>	(global) The number of columns in the distributed matrix <code>sub(C)</code> ($n \geq 0$).
<i>a</i>	(local) Pointer into the local memory to an array of size $lld\_a * LOCc(ja+m-1)$ if <i>side</i> = 'L', and $lld\_a * LOCc(ja+n-1)$ if <i>side</i> = 'R'. Contains the vectors that define the elementary reflectors, as returned by <code>p?sytrd</code>. If <i>side</i>='L', $lld\_a \geq \max(1, LOCr(ia+m-1))$; If <i>side</i>='R', $lld\_a \geq \max(1, LOCr(ia+n-1))$.
<i>ia, ja</i>	(global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix A .
<i>tau</i>	(local) Array of size of <i>ltau</i> where if <i>side</i> = 'L' and <i>uplo</i> = 'U', $ltau = LOCc(m\_a)$, if <i>side</i> = 'L' and <i>uplo</i> = 'L', $ltau = LOCc(ja+m-2)$, if <i>side</i> = 'R' and <i>uplo</i> = 'U', $ltau = LOCc(n\_a)$, if <i>side</i> = 'R' and <i>uplo</i> = 'L', $ltau = LOCc(ja+n-2)$. $tau[i]$ must contain the scalar factor of the elementary reflector $H(i+1)$, as returned by <code>p?sytrd</code> ($0 \leq i < ltau$). <i>tau</i> is tied to the distributed matrix A.
<i>c</i>	(local) Pointer into the local memory to an array of size $lld\_c * LOCc(jc+n-1)$. Contains the local pieces of the distributed matrix <code>sub(C)</code>.

<i>ic, jc</i>	(global) The row and column indices in the global matrix <i>C</i> indicating the first row and the first column of the submatrix <i>C</i> , respectively.
<i>desc</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>C</i> .
<i>work</i>	(local) Workspace array of size <i>lwork</i> .
<i>lwork</i>	(local or global) size of <i>work</i> , must be at least: <pre> if uplo = 'U', iaa= ia; jaa= ja+1, icc= ic; jcc= jc; else uplo = 'L', iaa= ia+1, jaa= ja; If side = 'L', icc= ic+1; jcc= jc; else icc= ic; jcc= jc+1; end if end if If side = 'L', mi= m-1; ni= n lwork≥max((nb_a*(nb_a-1))/2, (nqc0 + mpc0)*nb_a) + nb_a*nb_a else If side = 'R', mi= m; ni = n-1; lwork≥max((nb_a*(nb_a-1))/2, (nqc0 + max(npa0+numroc(numroc(ni+icoffc, nb_a, 0, 0, NPCOL), nb_a, 0, 0, lcmq), mpc0))*nb_a)+ nb_a*nb_a end if where lcmq = lcm/NPCOL with lcm = ilcm(NPROW, NPCOL), iroffa = mod(iaa-1, mb_a), icoffa = mod(jaa-1, nb_a), iarow = indxg2p(iaa, mb_a, MYROW, rsrc_a, NPROW), npa0 = numroc(ni+iroffa, mb_a, MYROW, iarow, NPROW), iroffc = mod(icc-1, mb_c), icoffc = mod(jcc-1, nb_c), icrow = indxg2p(icc, mb_c, MYROW, rsrc_c, NPROW), iccol = indxg2p(jcc, nb_c, MYCOL, csrc_c, NPCOL), mpc0 = numroc(mi+iroffc, mb_c, MYROW, icrow, NPROW), nqc0 = numroc(ni+icoffc, nb_c, MYCOL, iccol, NPCOL), </pre>

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

`ilcm`, `indxcg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the function `blacs_gridinfo`. If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `p?xerbla`.

Output Parameters

<code>c</code>	Overwritten by the product $Q*\text{sub}(C)$, or $Q'*\text{sub}(C)$, or $\text{sub}(C)*Q'$, or $\text{sub}(C)*Q$.
<code>work[0]</code>	On exit <code>work[0]</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) = 0: the execution is successful. < 0: if the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then <code>info</code> = $-(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then <code>info</code> = $-i$.

p?hetrd

Reduces a Hermitian matrix to Hermitian tridiagonal form by a unitary similarity transformation.

Syntax

```
void pchetrd (char *uplo , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , float *d , float *e , MKL_Complex8 *tau , MKL_Complex8 *work ,
MKL_INT *lwork , MKL_INT *info );

void pzhetrd (char *uplo , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *d , double *e , MKL_Complex16 *tau , MKL_Complex16 *work ,
MKL_INT *lwork , MKL_INT *info );
```

Include Files

- `mkl_scalapack.h`

Description

The `p?hetrd` function reduces a complex Hermitian matrix $\text{sub}(A)$ to Hermitian tridiagonal form T by a unitary similarity transformation:

$$Q*\text{sub}(A)*Q = T$$

where $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$.

Input Parameters

<i>uplo</i>	(global) Specifies whether the upper or lower triangular part of the Hermitian matrix sub(<i>A</i>) is stored: If <i>uplo</i> = 'U', upper triangular If <i>uplo</i> = 'L', lower triangular
<i>n</i>	(global) The order of the distributed matrix sub(<i>A</i>) ($n \geq 0$).
<i>a</i>	(local) Pointer into the local memory to an array of size $lld\_a * LOCc(ja+n-1)$. On entry, this array contains the local pieces of the Hermitian distributed matrix sub(<i>A</i>). If <i>uplo</i> = 'U', the leading <i>n</i> -by- <i>n</i> upper triangular part of sub(<i>A</i>) contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced. If <i>uplo</i> = 'L', the leading <i>n</i> -by- <i>n</i> lower triangular part of sub(<i>A</i>) contains the lower triangular part of the matrix, and its strictly upper triangular part is not referenced. (see <i>Application Notes</i> below).
<i>ia, ja</i>	(global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .
<i>work</i>	(local) Workspace array of size <i>lwork</i> .
<i>lwork</i>	(local or global) size of <i>work</i> , must be at least: $lwork \geq \max(NB * (np + 1), 3 * NB)$ where $NB = mb\_a = nb\_a$, $np = \text{numroc}(n, NB, MYROW, iarow, NPROW)$, $iarow = \text{indxg2p}(ia, NB, MYROW, rsrc\_a, NPROW)$. <i>indxg2p</i> and <i>numroc</i> are ScaLAPACK tool functions; MYROW, MYCOL, NPROW and NPCOL can be determined by calling the function <i>blacs_gridinfo</i> . If <i>lwork</i> = -1, then <i>lwork</i> is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by <i>pxerbla</i> .

Output Parameters

<i>a</i>	On exit, If <i>uplo</i> = 'U', the diagonal and first superdiagonal of sub(<i>A</i>) are overwritten by the corresponding elements of the tridiagonal matrix <i>T</i> , and the elements above the first superdiagonal, with the array <i>tau</i> , represent

the unitary matrix Q as a product of elementary reflectors; if $uplo = 'L'$, the diagonal and first subdiagonal of $sub(A)$ are overwritten by the corresponding elements of the tridiagonal matrix T , and the elements below the first subdiagonal, with the array tau , represent the unitary matrix Q as a product of elementary reflectors (see *Application Notes* below).

d

(local)

Arrays of size $LOCc(ja+n-1)$. The diagonal elements of the tridiagonal matrix T :

$$d[i] = A(i+1, i+1), 0 \leq i < LOCc(ja+n-1).$$

d is tied to the distributed matrix A .

e

(local)

Arrays of size $LOCc(ja+n-1)$ if $uplo = 'U'$; $LOCc(ja+n-2)$ - otherwise.

The off-diagonal elements of the tridiagonal matrix T :

$$e[i] = A(i+1, i+2), 0 \leq i < LOCc(ja+n-1) \text{ if } uplo = 'U',$$

$$e[i] = A(i+2, i+1) \text{ if } uplo = 'L'.$$

e is tied to the distributed matrix A .

tau

(local)

Array of size $LOCc(ja+n-1)$. This array contains the scalar factors of the elementary reflectors. tau is tied to the distributed matrix A .

$work[0]$

On exit $work[0]$ contains the minimum value of $lwork$ required for optimum performance.

$info$

(global)

= 0: the execution is successful.

< 0: if the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

Application Notes

If $uplo = 'U'$, the matrix Q is represented as a product of elementary reflectors

$$Q = H(n-1) * \dots * H(2) * H(1).$$

Each $H(i)$ has the form

$$H(i) = I - \tau * v * v',$$

where τ is a complex scalar, and v is a complex vector with $v(i+1:n) = 0$ and $v(i) = 1$; $v(1:i-1)$ is stored on exit in $A(ia:ia+i-2, ja+i)$, and τ in $tau[ja+i-2]$.

If $uplo = 'L'$, the matrix Q is represented as a product of elementary reflectors

$$Q = H(1) * H(2) * \dots * H(n-1).$$

Each $H(i)$ has the form

$$H(i) = I - \tau * v * v',$$

where τ is a complex scalar, and v is a complex vector with $v(1:i) = 0$ and $v(i+1) = 1$; $v(i+2:n)$ is stored on exit in $A(ia+i+1:ia+n-1, ja+i-1)$, and τ in $tau[ja+i-2]$.

The contents of `sub(A)` on exit are illustrated by the following examples with $n = 5$:

If `uplo = 'U'`:

$$\begin{bmatrix} d & e & v2 & v3 & v4 \\ & d & e & v3 & v4 \\ & & d & e & v4 \\ & & & d & e \\ & & & & d \end{bmatrix}$$

If `uplo = 'L'`:

$$\begin{bmatrix} d & & & & \\ e & d & & & \\ v1 & e & d & & \\ v1 & v2 & e & d & \\ v1 & v2 & v3 & e & d \end{bmatrix}$$

where d and e denote diagonal and off-diagonal elements of T , and v_i denotes an element of the vector defining $H(i)$.

p?unmtr

Multiplies a general matrix by the unitary transformation matrix from a reduction to tridiagonal form determined by p?hetrd.

Syntax

```
void pcunmtr (char *side , char *uplo , char *trans , MKL_INT *m , MKL_INT *n ,
MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *tau ,
MKL_Complex8 *c , MKL_INT *ic , MKL_INT *jc , MKL_INT *descc , MKL_Complex8 *work ,
MKL_INT *lwork , MKL_INT *info );
```

```
void pzunmtr (char *side , char *uplo , char *trans , MKL_INT *m , MKL_INT *n ,
MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *tau ,
MKL_Complex16 *c , MKL_INT *ic , MKL_INT *jc , MKL_INT *descc , MKL_Complex16 *work ,
MKL_INT *lwork , MKL_INT *info );
```

Include Files

- `mkl_scalapack.h`

Description

This function overwrites the general complex distributed m -by- n matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q * \text{sub}(C)$	$\text{sub}(C) * Q$
$trans = 'C':$	$Q^H * \text{sub}(C)$	$\text{sub}(C) * Q^H$

where Q is a complex unitary distributed matrix of order nq , with $nq = m$ if $side = 'L'$ and $nq = n$ if $side = 'R'$.

Q is defined as the product of $nq-1$ elementary reflectors, as returned by [p?hetrd](#).

If $uplo = 'U'$, $Q = H(nq-1) \dots H(2) H(1)$;

If $uplo = 'L'$, $Q = H(1) H(2) \dots H(nq-1)$.

Input Parameters

$side$	(global) = $'L'$: Q or Q^H is applied from the left. = $'R'$: Q or Q^H is applied from the right.
$trans$	(global) = $'N'$, no transpose, Q is applied. = $'C'$, conjugate transpose, Q^H is applied.
$uplo$	(global) = $'U'$: Upper triangle of $A(ia:*, ja:*)$ contains elementary reflectors from p?hetrd ; = $'L'$: Lower triangle of $A(ia:*, ja:*)$ contains elementary reflectors from p?hetrd
m	(global) The number of rows in the distributed matrix $\text{sub}(C)$ ($m \geq 0$).
n	(global) The number of columns in the distributed matrix $\text{sub}(C)$ ($n \geq 0$).
a	(local) Pointer into the local memory to an array of size $lld\_a * LOCc(ja+m-1)$ if $side = 'L'$, and $lld\_a * LOCc(ja+n-1)$ if $side = 'R'$. Contains the vectors which define the elementary reflectors, as returned by p?hetrd . If $side = 'L'$, $lld\_a \geq \max(1, LOCr(ia+m-1))$; If $side = 'R'$, $lld\_a \geq \max(1, LOCr(ia+n-1))$.
ia, ja	(global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively.
$desca$	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix A .
tau	(local)

Array of size of *ltau* where

```
If side = 'L' and uplo = 'U', ltau = LOCc(m_a),
if side = 'L' and uplo = 'L', ltau = LOCc(ja+m-2),
if side = 'R' and uplo = 'U', ltau = LOCc(n_a),
if side = 'R' and uplo = 'L', ltau = LOCc(ja+n-2).
```

tau[*i*] must contain the scalar factor of the elementary reflector $H(i+1)$, as returned by `p?hetrd` ($0 \leq i < ltau$). *tau* is tied to the distributed matrix *A*.

c

(local)

Pointer into the local memory to an array of size $lld\_c * LOCc(jc+n-1)$. Contains the local pieces of the distributed matrix sub (*C*).

ic, jc

(global) The row and column indices in the global matrix *C* indicating the first row and the first column of the submatrix *C*, respectively.

desc

(global and local) array of size *dlen_*. The array descriptor for the distributed matrix *C*.

work

(local)

Workspace array of size *lwork*.

lwork

(local or global) size of *work*, must be at least:

```
If uplo = 'U',
iaa= ia; jaa= ja+1, icc= ic; jcc= jc;
else uplo = 'L',
iaa= ia+1, jaa= ja;
If side = 'L',
icc= ic+1; jcc= jc;
else icc= ic; jcc= jc+1;
end if
end if
If side = 'L',
mi= m-1; ni= n
lwork ≥ max((nb_a*(nb_a-1))/2, (nqc0 + mpc0)*nb_a) + nb_a*nb_a
else
If side = 'R',
mi= m; ni= n-1;
lwork ≥ max((nb_a*(nb_a-1))/2, (nqc0 +
max(npa0+numroc(numroc(ni+icoffc, nb_a, 0, 0, NPCOL), nb_a,
0, 0, lcmq), mpc0))*nb_a) + nb_a*nb_a
end if
where lcmq = lcm/NPCOL with lcm = ilcm(NPROW, NPCOL),
```

```

iroffa = mod(iaa-1, mb_a),
icoffa = mod(jaa-1, nb_a),
iarow = indxcg2p(iaa, mb_a, MYROW, rsrc_a, NPROW),
npa0 = numroc(ni+iroffa, mb_a, MYROW, iarow, NPROW),
iroffc = mod(icc-1, mb_c),
icoffc = mod(jcc-1, nb_c),
icrow = indxcg2p(icc, mb_c, MYROW, rsrc_c, NPROW),
iccol = indxcg2p(jcc, nb_c, MYCOL, csrc_c, NPCOL),
mpc0 = numroc(mi+iroffc, mb_c, MYROW, icrow, NPROW),
nqc0 = numroc(ni+icoffc, nb_c, MYCOL, iccol, NPCOL),

```

NOTE

`mod(x,y)` is the integer remainder of `x/y`.

`ilcm`, `indxcg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the function `blacs_gridinfo`. If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

<code>c</code>	Overwritten by the product $Q \cdot \text{sub}(C)$, or $Q' \cdot \text{sub}(C)$, or $\text{sub}(C) \cdot Q'$, or $\text{sub}(C) \cdot Q$.
<code>work[0]</code>	On exit <code>work[0]</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) = 0: the execution is successful. < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j</i> - 1, had an illegal value, then <code>info</code> = $-(i \cdot 100 + j)$; if the <i>i</i> -th argument is a scalar and had an illegal value, then <code>info</code> = $-i$.

p?stebz

Computes the eigenvalues of a symmetric tridiagonal matrix by bisection.

Syntax

```

void psstebz (MKL_INT *ictxt , char *range , char *order , MKL_INT *n , float *vl ,
float *vu , MKL_INT *il , MKL_INT *iu , float *abstol , float *d , float *e , MKL_INT
*m , MKL_INT *nsplit , float *w , MKL_INT *iblock , MKL_INT *isplit , float *work ,
MKL_INT *lwork , MKL_INT *iwork , MKL_INT *liwork , MKL_INT *info );

```

```
void pdstebz (MKL_INT *ictxt , char *range , char *order , MKL_INT *n , double *vl ,
double *vu , MKL_INT *il , MKL_INT *iu , double *abstol , double *d , double *e ,
MKL_INT *m , MKL_INT *nsplit , double *w , MKL_INT *iblock , MKL_INT *isplit , double
*work , MKL_INT *lwork , MKL_INT *iwork , MKL_INT *liwork , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The `pdstebz` function computes the eigenvalues of a symmetric tridiagonal matrix in parallel. These may be all eigenvalues, all eigenvalues in the interval $[vl, vu]$, or the eigenvalues il through iu . A static partitioning of work is done at the beginning of `pdstebz` which results in all processes finding an (almost) equal number of eigenvalues.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

<i>ictxt</i>	(global) The BLACS context handle.
<i>range</i>	(global) Must be 'A' or 'V' or 'I'. If <i>range</i> = 'A', the function computes all eigenvalues. If <i>range</i> = 'V', the function computes eigenvalues in the interval $[vl, vu]$. If <i>range</i> = 'I', the function computes eigenvalues il through iu .
<i>order</i>	(global) Must be 'B' or 'E'. If <i>order</i> = 'B', the eigenvalues are to be ordered from smallest to largest within each split-off block. If <i>order</i> = 'E', the eigenvalues for the entire matrix are to be ordered from smallest to largest.
<i>n</i>	(global) The order of the tridiagonal matrix T ($n \geq 0$).
<i>vl, vu</i>	(global) If <i>range</i> = 'V', the function computes the lower and the upper bounds for the eigenvalues on the interval $[1, vu]$. If <i>range</i> = 'A' or 'I', <i>vl</i> and <i>vu</i> are not referenced.
<i>il, iu</i>	(global)

Constraint: $1 \leq il \leq iu \leq n$.

If $range = 'I'$, the index of the smallest eigenvalue is returned for il and of the largest eigenvalue for iu (assuming that the eigenvalues are in ascending order) must be returned.

If $range = 'A'$ or $'V'$, il and iu are not referenced.

abstol

(global)

The absolute tolerance to which each eigenvalue is required. An eigenvalue (or cluster) is considered to have converged if it lies in an interval of width *abstol*. If $abstol \leq 0$, then the tolerance is taken as $ulp||T||$, where *ulp* is the machine precision, and $||T||$ means the 1-norm of *T*.

Eigenvalues will be computed most accurately when *abstol* is set to the underflow threshold `slamch('U')`, not 0. Note that if eigenvectors are desired later by inverse iteration (`p?stein`), *abstol* should be set to $2 * p?lamch('S')$.

d

(global)

Array of size *n*.

Contains *n* diagonal elements of the tridiagonal matrix *T*. To avoid overflow, the matrix must be scaled so that its largest entry is no greater than the $overflow^{(1/2)} * underflow^{(1/4)}$ in absolute value, and for greatest accuracy, it should not be much smaller than that.

e

(global)

Array of size $n - 1$.

Contains $(n-1)$ off-diagonal elements of the tridiagonal matrix *T*. To avoid overflow, the matrix must be scaled so that its largest entry is no greater than $overflow^{(1/2)} * underflow^{(1/4)}$ in absolute value, and for greatest accuracy, it should not be much smaller than that.

work

(local)

Array of size $\max(5n, 7)$. This is a workspace array.

lwork

(local) The size of the *work* array must be $\geq \max(5n, 7)$.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

iwork

(local) Array of size $\max(4n, 14)$. This is a workspace array.

liwork

(local) The size of the *iwork* array must $\geq \max(4n, 14, NPROCS)$.

If *liwork* = -1, then *liwork* is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

<i>m</i>	(global) The actual number of eigenvalues found. $0 \leq m \leq n$
<i>nsplit</i>	(global) The number of diagonal blocks detected in <i>T</i> . $1 \leq nsplit \leq n$
<i>w</i>	(global) Array of size <i>n</i> . On exit, the first <i>m</i> elements of <i>w</i> contain the eigenvalues on all processes.
<i>iblock</i>	(global) Array of size <i>n</i> . At each row/column <i>j</i> where $e[j-1]$ is zero or small, the matrix <i>T</i> is considered to split into a block diagonal matrix. On exit <i>iblock</i> [<i>i</i>] specifies which block (from 1 to the number of blocks) the eigenvalue <i>w</i> [<i>i</i>] belongs to.

NOTE

In the (theoretically impossible) event that bisection does not converge for some or all eigenvalues, *info* is set to 1 and the ones for which it did not are identified by a negative block number.

<i>isplit</i>	(global) Array of size <i>n</i> . Contains the splitting points, at which <i>T</i> breaks up into submatrices. The first submatrix consists of rows/columns 1 to <i>isplit</i> [0], the second of rows/columns <i>isplit</i> [0]+1 through <i>isplit</i> [1], and so on, and the <i>nsplit</i> -th submatrix consists of rows/columns <i>isplit</i> [<i>nsplit</i> -2]+1 through <i>isplit</i> [<i>nsplit</i> -1]= <i>n</i> . (Only the first <i>nsplit</i> elements are used, but since the <i>nsplit</i> values are not known, <i>n</i> words must be reserved for <i>isplit</i> .)
<i>info</i>	(global) If <i>info</i> = 0, the execution is successful. If <i>info</i> < 0, if <i>info</i> = - <i>i</i> , the <i>i</i> -th argument has an illegal value. If <i>info</i> > 0, some or all of the eigenvalues fail to converge or are not computed. If <i>info</i> = 1, bisection fails to converge for some eigenvalues; these eigenvalues are flagged by a negative block number. The effect is that the eigenvalues may not be as accurate as the absolute and relative tolerances. If <i>info</i> = 2, mismatch between the number of eigenvalues output and the number desired. If <i>info</i> = 3: <i>range</i> ='I', and the Gershgorin interval initially used is incorrect. No eigenvalues are computed. Probable cause: the machine has a sloppy floating-point arithmetic. Increase the <i>fudge</i> parameter, recompile, and try again.

Description

The `p?stein` function computes the eigenvectors of a symmetric tridiagonal matrix T corresponding to specified eigenvalues, by inverse iteration. `p?stein` does not orthogonalize vectors that are on different processes. The extent of orthogonalization is controlled by the input parameter `lwork`. Eigenvectors that are to be orthogonalized are computed by the same process. `p?stein` decides on the allocation of work among the processes and then calls `?stein2` (modified LAPACK function) on each individual process. If insufficient workspace is allocated, the expected orthogonalization may not be done.

NOTE

If the eigenvectors obtained are not orthogonal, increase `lwork` and run the code again.

$p = \text{NPROW} * \text{NPCOL}$ is the total number of processes.

Input Parameters

n	(global) The order of the matrix T ($n \geq 0$).
m	(global) The number of eigenvectors to be returned.
d, e, w	(global) Arrays: d of size n contains the diagonal elements of T . e of size $n-1$ contains the off-diagonal elements of T .

w of size m contains all the eigenvalues grouped by split-off block. The eigenvalues are supplied from smallest to largest within the block. (Here the output array w from `p?stebz` with order = 'B' is expected. The array should be replicated in all processes.)

iblock

(global)

Array of size n . The submatrix indices associated with the corresponding eigenvalues in w : 1 for eigenvalues belonging to the first submatrix from the top, 2 for those belonging to the second submatrix, etc. (The output array *iblock* from `p?stebz` is expected here).

isplit

(global)

Array of size n . The splitting points at which T breaks up into submatrices. The first submatrix consists of rows/columns 1 to *isplit*[0], the second of rows/columns *isplit*[0]+1 through *isplit*[1], and so on, and the *nsplit*-th submatrix consists of rows/columns *isplit*[*nsplit*-2]+1 through *isplit*[*nsplit*-1]= n . (The output array *isplit* from `p?stebz` is expected here.)

orfac

(global)

orfac specifies which eigenvectors should be orthogonalized. Eigenvectors that correspond to eigenvalues within $orfac * ||T||$ of each other are to be orthogonalized. However, if the workspace is insufficient (see *lwork*), this tolerance may be decreased until all eigenvectors can be stored in one process. No orthogonalization is done if *orfac* is equal to zero. A default value of 1000 is used if *orfac* is negative. *orfac* should be identical on all processes

iz, jz

(global) The row and column indices in the global matrix Z indicating the first row and the first column of the submatrix Z , respectively.

descz

(global and local) array of size *dlen_*. The array descriptor for the distributed matrix Z .

work

(local).

Workspace array of size *lwork*.

lwork

(local)

lwork controls the extent of orthogonalization which can be done. The number of eigenvectors for which storage is allocated on each process is $nvec = \text{floor}((lwork - \max(5*n, np00*mq00))/n)$. Eigenvectors corresponding to eigenvalue clusters of size $(nvec - \text{ceil}(m/p) + 1)$ are guaranteed to be orthogonal (the orthogonality is similar to that obtained from `?stein2`).

NOTE

lwork must be no smaller than $\max(5*n, np00*mq00) + \text{ceil}(m/p) * n$ and should have the same input value on all processes.

It is the minimum value of *lwork* input on different processes that is significant.

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

iwork

(local)

Workspace array of size $3n+p+1$.

liwork

(local) The size of the array *iwork*. It must be greater than $3*n+p+1$.

If $liwork = -1$, then $liwork$ is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

z

(local)

Array of size `descz[dlen_-1], n/NPCOL + NB`. *z* contains the computed eigenvectors associated with the specified eigenvalues. Any vector which fails to converge is set to its current iterate after MAXIT iterations (See [stein2](#)). On output, *z* is distributed across the p processes in block cyclic format.

work

On exit, `work[0]` gives a lower bound on the workspace (*lwork*) that guarantees the user desired orthogonalization (see *orfac*). Note that this may overestimate the minimum workspace needed.

iwork

On exit, `iwork[0]` contains the amount of integer workspace required.

On exit, the `iwork[1]` through `iwork[p+1]` indicate the eigenvectors computed by each process. Process i computes eigenvectors indexed `iwork[i+1]+1` through `iwork[i+2]`.

ifail

(global) Array of size m . On normal exit, all elements of *ifail* are zero. If one or more eigenvectors fail to converge after MAXIT iterations (as in [stein](#)), then $info > 0$ is returned. If $\text{mod}(info, m+1) > 0$, then for $i=1$ to $\text{mod}(info, m+1)$, the eigenvector corresponding to the eigenvalue `w[ifail[i-1]-1]` failed to converge (*w* refers to the array of eigenvalues on output).

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

iclustr

(global) Array of size $2*p$.

This output array contains indices of eigenvectors corresponding to a cluster of eigenvalues that could not be orthogonalized due to insufficient workspace (see *lwork*, *orfac* and *info*). Eigenvectors corresponding to clusters of eigenvalues indexed `iclustr(2*I-1)` to `iclustr(2*I)`, $i = 1$ to $info/(m+1)$, could not be orthogonalized due to lack of workspace.

Hence the eigenvectors corresponding to these clusters may not be orthogonal. *iclustr* is a zero terminated array: $iclustr[2*k-1] \neq 0$ and $iclustr[2*k] = 0$ if and only if k is the number of clusters.

gap

(global)

This output array contains the gap between eigenvalues whose eigenvectors could not be orthogonalized. The $info/m$ output values in this array correspond to the $info/(m+1)$ clusters indicated by the array *iclustr*. As a result, the dot product between eigenvectors corresponding to the i -th cluster may be as high as $(O(n)*macheps)/gap[i-1]$.

info

(global)

If $info = 0$, the execution is successful.

If $info < 0$: If the i -th argument is an array and the j -th entry, indexed $j-1$, had an illegal value, then $info = -(i*100+j)$,

If the i -th argument is a scalar and had an illegal value, then $info = -i$.

If $info < 0$: if $info = -i$, the i -th argument had an illegal value.

If $info > 0$: if $\text{mod}(info, m+1) = i$, then i eigenvectors failed to converge in MAXIT iterations. Their indices are stored in the array *ifail*. If $info/(m+1) = i$, then eigenvectors corresponding to i clusters of eigenvalues could not be orthogonalized due to insufficient workspace. The indices of the clusters are stored in the array *iclustr*.

Nonsymmetric Eigenvalue Problems

This section describes ScaLAPACK routines for solving nonsymmetric eigenvalue problems, computing the Schur factorization of general matrices, as well as performing a number of related computational tasks.

To solve a nonsymmetric eigenvalue problem with ScaLAPACK, you usually need to reduce the matrix to the upper Hessenberg form and then solve the eigenvalue problem with the Hessenberg matrix obtained.

Table "Computational Routines for Solving Nonsymmetric Eigenproblems" lists ScaLAPACK routines for reducing the matrix to the upper Hessenberg form by an orthogonal (or unitary) similarity transformation $A = QHQ^H$, as well as routines for solving eigenproblems with Hessenberg matrices, and multiplying the matrix after reduction.

Computational Routines for Solving Nonsymmetric Eigenproblems

Operation performed	General matrix	Orthogonal/Unitary matrix	Hessenberg matrix
Reduce to Hessenberg form $A = QHQ^H$	p?gehrd		
Multiply the matrix after reduction		p?ormhr / p?unmhr	
Find eigenvalues and Schur factorization			p?lahqr

[p?gehrd](#)

Reduces a general matrix to upper Hessenberg form.

Syntax

```
void psgehrd (MKL_INT *n , MKL_INT *ilo , MKL_INT *ihi , float *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , float *tau , float *work , MKL_INT *lwork , MKL_INT
*info );

void pdgehrd (MKL_INT *n , MKL_INT *ilo , MKL_INT *ihi , double *a , MKL_INT *ia ,

MKL_INT *lwork , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The `p?gehrd` function reduces a real/complex general distributed matrix $\text{sub}(A)$ to upper Hessenberg form H by an orthogonal or unitary similarity transformation

$$Q^* \text{sub}(A) Q = H,$$

where $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$.

Input Parameters

<i>n</i>	(global). The order of the distributed matrix $\text{sub}(A)$ ($n \geq 0$).
<i>ilo, ihi</i>	(global). It is assumed that $\text{sub}(A)$ is already upper triangular in rows $\text{ia}:\text{ia}+\text{ilo}-2$ and $\text{ia}+\text{ihi}:\text{ia}+n-1$ and columns $\text{ja}:\text{ja}+\text{ilo}-2$ and $\text{ja}+\text{ihi}:\text{ja}+n-1$. (See <i>Application Notes</i> below). If $n > 0$, $1 \leq \text{ilo} \leq \text{ihi} \leq n$; otherwise set $\text{ilo} = 1$, $\text{ihi} = n$.
<i>a</i>	(local) Pointer into the local memory to an array of size $\text{lld}_a * \text{LOCc}(\text{ja}+n-1)$. On entry, this array contains the local pieces of the n -by- n general distributed matrix $\text{sub}(A)$ to be reduced.
<i>ia, ja</i>	(global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively.
<i>desca</i>	(global and local) array of size $\text{dlen}_$. The array descriptor for the distributed matrix A .
<i>work</i>	(local) Workspace array of size lwork .
<i>lwork</i>	(local or global) size of the array <i>work</i> . <i>lwork</i> is local input and must be at least

```

lwork ≥ NB*NB + NB*max(ihip+1, ihlp+inlq)

where NB = mb_a = nb_a,
iroffa = mod(ia-1, NB),
icoffa = mod(ja-1, NB),
ioff = mod(ia+ilo-2, NB), iarow = indxg2p(ia, NB, MYROW,
rsrc_a, NPROW), ihip = numroc(ihi+iroffa, NB, MYROW, iarow,
NPROW),
ilrow = indxg2p(ia+ilo-1, NB, MYROW, rsrc_a, NPROW),
ihlp = numroc(ihi-ilo+ioff+1, NB, MYROW, ilrow, NPROW),
ilcol = indxg2p(ja+ilo-1, NB, MYCOL, csrc_a, NPCOL),
inlq = numroc(n-ilo+ioff+1, NB, MYCOL, ilcol, NPCOL),

```

NOTE

`mod(x,y)` is the integer remainder of x/y .

`indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the function `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by [pxerbla](#).

Output Parameters*a*

On exit, the upper triangle and the first subdiagonal of `sub(A)` are overwritten with the upper Hessenberg matrix *H*, and the elements below the first subdiagonal, with the array *tau*, represent the orthogonal/unitary matrix *Q* as a product of elementary reflectors (see *Application Notes* below).

tau

(local).

Array of size at least $\max(ja+n-2)$.

The scalar factors of the elementary reflectors (see *Application Notes* below). Elements *ja:ja+ilo-2* and *ja+ihi:ja+n-2* of the global vector *tau* are set to zero. *tau* is tied to the distributed matrix *A*.

work[0]

On exit *work[0]* contains the minimum value of `lwork` required for optimum performance.

info

(global)

= 0: the execution is successful.

< 0: if the *i*-th argument is an array and the *j*-th entry, indexed *j* - 1, had an illegal value, then *info* = $-(i*100+j)$; if the *i*-th argument is a scalar and had an illegal value, then *info* = $-i$.

Application Notes

The matrix Q is represented as a product of $(ihi-ilo)$ elementary reflectors

$$Q = H(ilo)*H(ilo+1)*...*H(ihi-1).$$

Each $H(i)$ has the form

$$H(i) = I - \tau v v'$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(1:i) = 0$, $v(i+1) = 1$ and $v(ihi+1:n) = 0$; $v(i+2:ihi)$ is stored on exit in $A(ia+ilo+i:ia+ihi-1, ja+ilo+i-2)$, and τ in $\tau[ja+ilo+i-3]$. The contents of A

$(ia:ia+n-1, ja:ja+n-1)$ are illustrated by the following example, with $n = 7$, $ilo = 2$ and $ihi = 6$:

on entry

$$\begin{bmatrix} a & a & a & a & a & a & a \\ & a & a & a & a & a & a \\ & a & a & a & a & a & a \\ & a & a & a & a & a & a \\ & a & a & a & a & a & a \\ & a & a & a & a & a & a \\ & & & & & & a \end{bmatrix}$$

on exit

$$\begin{bmatrix} a & a & a & h & h & h & a \\ & a & h & h & h & h & a \\ & h & h & h & h & h & h \\ v2 & h & h & h & h & h & h \\ v2 & v3 & h & h & h & h & h \\ v2 & v3 & v4 & h & h & h & h \\ & & & & & & a \end{bmatrix}$$

where a denotes an element of the original matrix $\text{sub}(A)$, h denotes a modified element of the upper Hessenberg matrix H , and v_i denotes an element of the vector defining $H(ja+ilo+i-2)$.

*lwork , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The p?ormhr function overwrites the general real distributed m -by- n matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q * \text{sub}(C)$	$\text{sub}(C) * Q$
$trans = 'T':$	$Q^T * \text{sub}(C)$	$\text{sub}(C) * Q^T$

where Q is a real orthogonal distributed matrix of order nq , with $nq = m$ if $side = 'L'$ and $nq = n$ if $side = 'R'$.

Q is defined as the product of $ihi-ilo$ elementary reflectors, as returned by p?gehrd.

$Q = H(ilo) H(ilo+1) \dots H(ihi-1)$.

Input Parameters

$side$	(global) $= 'L'$: Q or Q^T is applied from the left. $= 'R'$: Q or Q^T is applied from the right.
$trans$	(global) $= 'N'$, no transpose, Q is applied. $= 'T'$, transpose, Q^T is applied.
m	(global) The number of rows in the distributed matrix sub (C) ($m \geq 0$).
n	(global) The number of columns in the distributed matrix sub (C) ($n \geq 0$).
ilo, ihi	(global) ilo and ihi must have the same values as in the previous call of p?gehrd. Q is equal to the unit matrix except for the distributed submatrix $Q(ia + ilo:ia+ihi-1, ja+ilo:ja+ihi-1)$.

If $side = 'L'$, $1 \leq ilo \leq ihi \leq \max(1, m)$;

If $side = 'R'$, $1 \leq ilo \leq ihi \leq \max(1, n)$;

ilo and ihi are relative indexes.

a

(local)

Pointer into the local memory to an array of size $lld\_a * LOCC(ja+m-1)$ if $side = 'L'$, and $lld\_a * LOCC(ja+n-1)$ if $side = 'R'$.

Contains the vectors which define the elementary reflectors, as returned by `p?gehrd`.

ia, ja

(global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively.

$desca$

(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix A .

tau

(local)

Array of size $LOCC(ja+m-2)$ if $side = 'L'$, and $LOCC(ja+n-2)$ if $side = 'R'$.

$tau[j]$ contains the scalar factor of the elementary reflector $H(j+1)$ as returned by `p?gehrd` ($0 \leq j < \text{size}(tau)$). tau is tied to the distributed matrix A .

c

(local)

Pointer into the local memory to an array of size $lld\_c * LOCC(jc+n-1)$.

Contains the local pieces of the distributed matrix $\text{sub}(C)$.

ic, jc

(global) The row and column indices in the global matrix C indicating the first row and the first column of the submatrix C , respectively.

$descc$

(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix C .

$work$

(local)

Workspace array with size $lwork$.

$lwork$

(local or global)

The size of the array $work$.

$lwork$ must be at least $iaa = ia + ilo$; $jaa = ja + ilo - 1$;

If $side = 'L'$,

$mi = ihi - ilo$; $ni = n$; $icc = ic + ilo$; $jcc = jc$;

$lwork \geq \max((nb\_a * (nb\_a - 1)) / 2, (nqc0 + mpc0) * nb\_a) + nb\_a * nb\_a$

else if $side = 'R'$,

$mi = m$; $ni = ihi - ilo$; $icc = ic$; $jcc = jc + ilo$;

$lwork \geq \max((nb\_a * (nb\_a - 1)) / 2, (nqc0 + \max(npa0 + \text{numroc}(\text{numroc}(ni + icoffc, nb\_a, 0, 0, NPCOL), nb\_a, 0, 0, lcmq), mpc0)) * nb\_a) + nb\_a * nb\_a$

end if

```

where  $lcmq = lcm/NPCOL$  with  $lcm = ilcm(NPROW, NPCOL)$ ,
 $iroffa = \text{mod}(iaa-1, mb\_a)$ ,
 $icoffa = \text{mod}(jaa-1, nb\_a)$ ,
 $iarow = \text{indxg2p}(iaa, mb\_a, MYROW, rsrc\_a, NPROW)$ ,
 $npa0 = \text{numroc}(ni+iroffa, mb\_a, MYROW, iarow, NPROW)$ ,
 $iroffc = \text{mod}(icc-1, mb\_c)$ ,  $icoffc = \text{mod}(jcc-1, nb\_c)$ ,
 $icrow = \text{indxg2p}(icc, mb\_c, MYROW, rsrc\_c, NPROW)$ ,
 $iccol = \text{indxg2p}(jcc, nb\_c, MYCOL, csrc\_c, NPCOL)$ ,
 $mpc0 = \text{numroc}(mi+iroffc, mb\_c, MYROW, icrow, NPROW)$ ,
 $nqc0 = \text{numroc}(ni+icoffc, nb\_c, MYCOL, iccol, NPCOL)$ ,

```

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

$ilcm$, indxg2p and numroc are ScaLAPACK tool functions; $MYROW$, $MYCOL$, $NPROW$ and $NPCOL$ can be determined by calling the function `blacs_gridinfo`.

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `p?erbla`.

Output Parameters

c	$\text{sub}(C)$ is overwritten by $Q*\text{sub}(C)$, or $Q'*\text{sub}(C)$, or $\text{sub}(C)*Q'$, or $\text{sub}(C)*Q$.
$work[0]$	On exit $work[0]$ contains the minimum value of $lwork$ required for optimum performance.
$info$	(global) = 0: the execution is successful. < 0: if the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then $info = -(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then $info = -i$.

See Also

Description

This function overwrites the general complex distributed m -by- n matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$ with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q * \text{sub}(C)$	$\text{sub}(C) * Q$
$trans = 'H':$	$Q^H * \text{sub}(C)$	$\text{sub}(C) * Q^H$

where Q is a complex unitary distributed matrix of order nq , with $nq = m$ if $side = 'L'$ and $nq = n$ if $side = 'R'$.

Q is defined as the product of $ihi-ilo$ elementary reflectors, as returned by [p?gehrd](#).

$Q = H(ilo) H(ilo+1) \dots H(ihi-1)$.

Input Parameters

<i>side</i>	(global) $= 'L'$: Q or Q^H is applied from the left. $= 'R'$: Q or Q^H is applied from the right.
<i>trans</i>	(global) $= 'N'$, no transpose, Q is applied. $= 'C'$, conjugate transpose, Q^H is applied.
<i>m</i>	(global) The number of rows in the distributed matrix sub (C) ($m \geq 0$).
<i>n</i>	(global) The number of columns in the distributed matrix sub (C) ($n \geq 0$).
<i>ilo, ihi</i>	(global) These must be the same parameters <i>ilo</i> and <i>ihi</i> , respectively, as supplied to p?gehrd . Q is equal to the unit matrix except in the distributed submatrix $Q(ia+ilo:ia+ihi-1, ja+ilo:ja+ihi-1)$. If $side = 'L'$, then $1 \leq ilo \leq ihi \leq \max(1, m)$. If $side = 'R'$, then $1 \leq ilo \leq ihi \leq \max(1, n)$ <i>ilo</i> and <i>ihi</i> are relative indexes.

<i>a</i>	(local) Pointer into the local memory to an array of size $lld\_a * LOCc(ja+m-1)$ if $side = 'L'$, and $lld\_a * LOCc(ja+n-1)$ if $side = 'R'$. Contains the vectors which define the elementary reflectors, as returned by <code>p?gehrd</code>.
<i>ia, ja</i>	(global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the submatrix <i>A</i>, respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i>. The array descriptor for the distributed matrix <i>A</i>.
<i>tau</i>	(local) Array of size $LOCc(ja+m-2)$, if $side = 'L'$, and $LOCc(ja+n-2)$ if $side = 'R'$. <i>tau[j]</i> contains the scalar factor of the elementary reflector $H(j+1)$ as returned by <code>p?gehrd</code> ($0 \leq j < \text{size}(\text{tau})$). <i>tau</i> is tied to the distributed matrix <i>A</i>.
<i>c</i>	(local) Pointer into the local memory to an array of size $lld\_c * LOCc(jc+n-1)$. Contains the local pieces of the distributed matrix sub(<i>C</i>).
<i>ic, jc</i>	(global) The row and column indices in the global matrix <i>C</i> indicating the first row and the first column of the submatrix <i>C</i>, respectively.
<i>descc</i>	(global and local) array of size <i>dlen_</i>. The array descriptor for the distributed matrix <i>C</i>.
<i>work</i>	(local) Workspace array with size <i>lwork</i>.
<i>lwork</i>	(local or global) The size of the array <i>work</i>. <i>lwork</i> must be at least $iaa = ia + ilo; jaa = ja + ilo - 1;$ If $side = 'L', mi = ihi - ilo; ni = n; icc = ic + ilo; jcc = jc;$ $lwork \geq \max((nb\_a * (nb\_a - 1)) / 2, (nqc0 + mpc0) * nb\_a) + nb\_a * nb\_a$ else if $side = 'R',$ $mi = m; ni = ihi - ilo; icc = ic; jcc = jc + ilo;$ $lwork \geq \max((nb\_a * (nb\_a - 1)) / 2, (nqc0 +$ $\max(npa0 + \text{numroc}(\text{numroc}(ni + icoffc, nb\_a, 0, 0, NPCOL), nb\_a,$ $0, 0, lcmq), mpc0)) * nb\_a) + nb\_a * nb\_a$ end if where $lcmq = lcm / NPCOL$ with $lcm = ilcm(NPROW, NPCOL),$ $iroffa = \text{mod}(iaa - 1, mb\_a),$ $icoffa = \text{mod}(jaa - 1, nb\_a),$ $iarow = \text{indxg2p}(iaa, mb\_a, MYROW, rsrc\_a, NPROW),$

```
npa0 = numroc(ni+iroffa, mb_a, MYROW, iarow, NPROW),
iroffc = mod(icc-1, mb_c),
icoffc = mod(jcc-1, nb_c),
icrow = indxc2p(icc, mb_c, MYROW, rsrc_c, NPROW),
iccol = indxc2p(jcc, nb_c, MYCOL, csrc_c, NPCOL),
mpc0 = numroc(mi+iroffc, mb_c, MYROW, icrow, NPROW),
nqc0 = numroc(ni+icoffc, nb_c, MYCOL, iccol, NPCOL),
```

NOTE

`mod(x,y)` is the integer remainder of x/y .

`ilcm`, `indxc2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the function `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

<code>c</code>	C is overwritten by $Q^* \text{sub}(C)$ or $Q^* \text{sub}(C)$ or $\text{sub}(C)^* Q'$ or $\text{sub}(C)^* Q$.
<code>work[0]</code>	On exit <code>work[0]</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) = 0: the execution is successful. < 0: if the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then <code>info</code> = $-(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then <code>info</code> = $-i$.

p?lahqr

Computes the Schur decomposition and/or eigenvalues of a matrix already in Hessenberg form.

Syntax

```
void pslahqr (MKL_INT *wantt , MKL_INT *wantz , MKL_INT *n , MKL_INT *ilo , MKL_INT
*ihi , float *a , MKL_INT *desca , float *wr , float *wi , MKL_INT *iloz , MKL_INT
*ihiz , float *z , MKL_INT *descz , float *work , MKL_INT *lwork , MKL_INT *iwork ,
MKL_INT *ilwork , MKL_INT *info );
```

```
void pdlahqr (MKL_INT *wantt , MKL_INT *wantz , MKL_INT *n , MKL_INT *ilo , MKL_INT
*ihi , double *a , MKL_INT *desca , double *wr , double *wi , MKL_INT *iloz , MKL_INT
*ihiz , double *z , MKL_INT *descz , double *work , MKL_INT *lwork , MKL_INT *iwork ,
MKL_INT *ilwork , MKL_INT *info );
```

Include Files

- `mkl_scalapack.h`

Description

This is an auxiliary function used to find the Schur decomposition and/or eigenvalues of a matrix already in Hessenberg form from columns *ilo* and *ihi*.

Input Parameters

<i>wantt</i>	(global) If <i>wantt</i> ≠ 0, the full Schur form <i>T</i> is required; If <i>wantt</i> = 0, only eigenvalues are required.
<i>wantz</i>	(global) If <i>wantz</i> ≠ 0, the matrix of Schur vectors <i>Z</i> is required; If <i>wantz</i> = 0, Schur vectors are not required.
<i>n</i>	(global) The order of the Hessenberg matrix <i>A</i> (and <i>z</i> if <i>wantz</i> is non-zero). $n \geq 0$.
<i>ilo, ihi</i>	(global) It is assumed that <i>A</i> is already upper quasi-triangular in rows and columns <i>ihi</i> +1: <i>n</i> , and that $A(ilo, ilo-1) = 0$ (unless <i>ilo</i> = 1). <code>p?lahqr</code> works primarily with the Hessenberg submatrix in rows and columns <i>ilo</i> to <i>ihi</i> , but applies transformations to all of <i>H</i> if <i>wantt</i> is non-zero. $1 \leq ilo \leq \max(1, ihi); ihi \leq n$.
<i>a</i>	(global) Array, of size $lld\_a * LOCc(n)$. On entry, the upper Hessenberg matrix <i>A</i> .
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .
<i>iloz, ihiz</i>	(global) Specify the rows of the matrix <i>Z</i> to which transformations must be applied if <i>wantz</i> is non-zero. $1 \leq iloz \leq ilo; ihi \leq ihiz \leq n$.
<i>z</i>	(global) Array. If <i>wantz</i> is non-zero, on entry <i>z</i> must contain the current matrix <i>Z</i> of transformations accumulated by <code>pdhseqr</code> . If <i>wantz</i> is zero, <i>z</i> is not referenced.
<i>descz</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>Z</i> .
<i>work</i>	(local) Workspace array with size <i>lwork</i> .
<i>lwork</i>	(local) The size of <i>work</i> . <i>lwork</i> is assumed big enough so that $lwork \geq 3*n + \max(2*\max(lld\_z, lld\_a) + 2*LOCq(n), 7*\text{ceil}(n/hbl) / lcm(NPROW, NPCOL))$.

If $lwork = -1$, then $work[0]$ gets set to the above number and the code returns immediately.

$iwork$ (global and local) array of size $ilwork$.

$ilwork$ (local) This holds some of the $iblk$ integer arrays.

Output Parameters

a On exit, if $wantt$ is non-zero, A is upper quasi-triangular in rows and columns $ilo:ihi$, with any 2-by-2 or larger diagonal blocks not yet in standard form. If $wantt$ is zero, the contents of A are unspecified on exit.

$work[0]$ On exit $work[0]$ contains the minimum value of $lwork$ required for optimum performance.

wr, wi (global replicated output)
Arrays of size n each. The real and imaginary parts, respectively, of the computed eigenvalues ilo to ihi are stored in the corresponding elements of wr and wi . If two eigenvalues are computed as a complex conjugate pair, they are stored in consecutive elements of wr and wi , say the i -th and $(i+1)$ -th, with $wi[i-1] > 0$ and $wi[i] < 0$. If $wantt$ is zero, the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in A . A may be returned with larger diagonal blocks until the next release.

z On exit z has been updated; transformations are applied only to the submatrix $Z(ilo:ihiz, ilo:ihi)$.

$info$ (global)
= 0: the execution is successful.
< 0: the parameter number - $info$ is incorrect or inconsistent
> 0: $p?lahqr$ failed to compute all the eigenvalues ilo to ihi in a total of $30 * (ihi - ilo + 1)$ iterations; if $info = i$, elements $i+1: ihiz$ of wr and wi contain the eigenvalues that have been successfully computed.

Singular Value Decomposition

This section describes ScaLAPACK routines for computing the singular value decomposition (SVD) of a general m -by- n matrix A (see "[Singular Value Decomposition](#)" in LAPACK chapter).

To find the SVD of a general matrix A , this matrix is first reduced to a bidiagonal matrix B by a unitary (orthogonal) transformation, and then SVD of the bidiagonal matrix is computed. Note that the SVD of B is computed using the LAPACK routine `?bdsqr`.

Table "[Computational Routines for Singular Value Decomposition \(SVD\)](#)" lists ScaLAPACK computational routines for performing this decomposition.

Computational Routines for Singular Value Decomposition (SVD)

Operation	General matrix	Orthogonal/unitary matrix
Reduce A to a bidiagonal matrix	<code>p?gebrd</code>	
Multiply matrix after reduction		<code>p?ormbr/p?unmbr</code>

p?gebrd

Reduces a general matrix to bidiagonal form.

Syntax

```
void psgebrd (MKL_INT *m , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , float *d , float *e , float *tauq , float *taup , float *work , MKL_INT
*lwork , MKL_INT *info );

void pdgebrd (MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *d , double *e , double *tauq , double *taup , double *work ,
MKL_INT *lwork , MKL_INT *info );

void pcgebrd (MKL_INT *m , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,

MKL_Complex8 *work , MKL_INT *lwork , MKL_INT *info );

void pzgebrd (MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *d , double *e , MKL_Complex16 *tauq , MKL_Complex16 *taup ,
MKL_Complex16 *work , MKL_INT *lwork , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The p?gebrd function reduces a real/complex general m -by- n distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$ to upper or lower bidiagonal form B by an orthogonal/unitary transformation:

$$Q^* \text{sub}(A) P = B.$$

If $m \geq n$, B is upper bidiagonal; if $m < n$, B is lower bidiagonal.

Input Parameters

m	(global) The number of rows in the distributed matrix $\text{sub}(A)$ ($m \geq 0$).
n	(global) The number of columns in the distributed matrix $\text{sub}(A)$ ($n \geq 0$).
a	(local) Real pointer into the local memory to an array of size $lld\_a * LOCC(ja+n-1)$. On entry, this array contains the distributed matrix $\text{sub}(A)$.
ia, ja	(global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively.
$desca$	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix A .
$work$	(local) Workspace array of size $lwork$.
$lwork$	(local or global) size of $work$, must be at least: $lwork \geq nb * (mpa0 + nqa0 + 1) + nqa0$ where $nb = mb\_a = nb\_a$,

```

iroffa = mod(ia-1, nb),
icoffa = mod(ja-1, nb),
iarow = indxcg2p(ia, nb, MYROW, rsrc_a, NPROW),
iacol = indxcg2p(ja, nb, MYCOL, csrc_a, NPCOL),
mpa0 = numroc(m + iroffa, nb, MYROW, iarow, NPROW),
nqa0 = numroc(n + icoffa, nb, MYCOL, iacol, NPCOL),

```

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

`indxcg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the function `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

a

On exit, if $m \geq n$, the diagonal and the first superdiagonal of $\text{sub}(A)$ are overwritten with the upper bidiagonal matrix B ; the elements below the diagonal, with the array *tauq*, represent the orthogonal/unitary matrix Q as a product of elementary reflectors, and the elements above the first superdiagonal, with the array *taup*, represent the orthogonal matrix P as a product of elementary reflectors. If $m < n$, the diagonal and the first subdiagonal are overwritten with the lower bidiagonal matrix B ; the elements below the first subdiagonal, with the array *tauq*, represent the orthogonal/unitary matrix Q as a product of elementary reflectors, and the elements above the diagonal, with the array *taup*, represent the orthogonal matrix P as a product of elementary reflectors. See *Application Notes* below.

d

(local)

Array of size $LOCc(ja + \min(m, n) - 1)$ if $m \geq n$ and $LOCr(ia + \min(m, n) - 1)$ otherwise. The distributed diagonal elements of the bidiagonal matrix B : $d[i] = A(i+1, i+1)$, $0 \leq i < \text{size}(d)$.

d is tied to the distributed matrix A .

e

(local)

Array of size $LOCr(ia + \min(m, n) - 1)$ if $m \geq n$; $LOCc(ja + \min(m, n) - 2)$ otherwise. The distributed off-diagonal elements of the bidiagonal distributed matrix B :

If $m \geq n$, $e[i] = A(i+1, i+2)$ for $i = 0, 1, \dots, n-2$; if $m < n$, $e[i] = A(i+2, i+1)$ for $i = 0, 1, \dots, m-2$. *e* is tied to the distributed matrix A .

tauq, *taup*

(local)

Arrays of size $LOCc(ja+\min(m,n)-1)$ for τ_{auq} and $LOCr(ia+\min(m,n)-1)$ for τ_{aup} . Contain the scalar factors of the elementary reflectors that represent the orthogonal/unitary matrices Q and P , respectively. τ_{auq} and τ_{aup} are tied to the distributed matrix A . See *Application Notes* below.

`work[0]`

On exit `work[0]` contains the minimum value of `lwork` required for optimum performance.

`info`

(global)

= 0: the execution is successful.

< 0: if the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then `info` = $-(i*100+j)$; if the i -th argument is a scalar and had an illegal value, then `info` = $-i$.

Application Notes

The matrices Q and P are represented as products of elementary reflectors:

If $m \geq n$,

$Q = H(1)*H(2)*...*H(n)$, and $P = G(1)*G(2)*...*G(n-1)$.

Each $H(i)$ and $G(i)$ has the form:

$H(i) = I - \tau_{auq} * v * v'$ and $G(i) = I - \tau_{aup} * u * u'$

where τ_{auq} and τ_{aup} are real/complex scalars, and v and u are real/complex vectors;

$v(1:i-1) = 0$, $v(i) = 1$, and $v(i+1:m)$ is stored on exit in $A(ia+i:ia+m-1, ja+i-1)$;

$u(1:i) = 0$, $u(i+1) = 1$, and $u(i+2:n)$ is stored on exit in $A(ia+i-1, ja+i+1:ja+n-1)$;

τ_{auq} is stored in $\tau_{auq}[ja+i-2]$ and τ_{aup} in $\tau_{aup}[ia+i-2]$.

If $m < n$,

$Q = H(1)*H(2)*...*H(m-1)$, and $P = G(1)*G(2)*...*G(m)$

Each $H(i)$ and $G(i)$ has the form:

$H(i) = I - \tau_{auq} * v * v'$ and $G(i) = I - \tau_{aup} * u * u'$

here τ_{auq} and τ_{aup} are real/complex scalars, and v and u are real/complex vectors;

$v(1:i) = 0$, $v(i+1) = 1$, and $v(i+2:m)$ is stored on exit in $A(ia+i:ia+m-1, ja+i-1)$; $u(1:i-1) = 0$, $u(i) = 1$, and $u(i+1:n)$ is stored on exit in $A(ia+i-1, ja+i+1:ja+n-1)$;

τ_{auq} is stored in $\tau_{auq}[ja+i-2]$ and τ_{aup} in $\tau_{aup}[ia+i-2]$.

The contents of $\text{sub}(A)$ on exit are illustrated by the following examples:

$m = 6$ and $n = 5 (m > n)$:

$$\begin{bmatrix} d & e & u1 & u1 & u1 \\ v1 & d & e & u2 & u2 \\ v1 & v2 & d & e & u3 \\ v1 & v2 & v3 & d & e \\ v1 & v2 & v3 & v4 & d \\ v1 & v2 & v3 & v4 & v5 \end{bmatrix}$$

$m = 5$ and $n = 6 (m < n)$:

$$\begin{bmatrix} d & u1 & u1 & u1 & u1 & u1 \\ e & d & u2 & u2 & u2 & u2 \\ v1 & e & d & u3 & u3 & u3 \\ v1 & v2 & e & d & u4 & u4 \\ v1 & v2 & v3 & e & d & u5 \end{bmatrix}$$

where d and e denote diagonal and off-diagonal elements of B , vi denotes an element of the vector defining $H(i)$, and ui an element of the vector defining $G(i)$.

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

p?ormbr

Multiplies a general matrix by one of the orthogonal matrices from a reduction to bidiagonal form determined by p?gebrd.

Syntax

```
void psormbr (char *vect , char *side , char *trans , MKL_INT *m , MKL_INT *n ,
MKL_INT *k , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *tau ,
float *c , MKL_INT *ic , MKL_INT *jc , MKL_INT *desc , float *work , MKL_INT *lwork ,
MKL_INT *info );
```

```
void pdormbr (char *vect , char *side , char *trans , MKL_INT *m , MKL_INT *n ,
MKL_INT *k , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *tau ,
double *c , MKL_INT *ic , MKL_INT *jc , MKL_INT *desc , double *work , MKL_INT
*lwork , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

If $vect = 'Q'$, the `p?ormbr` function overwrites the general real distributed m -by- n matrix $sub(C) = C(ic:ic+m-1, jc:jc+n-1)$ with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q \text{ sub}(C)$	$\text{sub}(C) Q$
$trans = 'T':$	$Q^T \text{ sub}(C)$	$\text{sub}(C) Q^T$

If $vect = 'P'$, the function overwrites $\text{sub}(C)$ with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$P \text{ sub}(C)$	$\text{sub}(C) P$
$trans = 'T':$	$P^T \text{ sub}(C)$	$\text{sub}(C) P^T$

Here Q and P^T are the orthogonal distributed matrices determined by [p?gebrd](#) when reducing a real distributed matrix $A(ia:*, ja:*)$ to bidiagonal form: $A(ia:*, ja:*) = Q*B*P^T$. Q and P^T are defined as products of elementary reflectors $H(i)$ and $G(i)$ respectively.

Let $nq = m$ if $side = 'L'$ and $nq = n$ if $side = 'R'$. Therefore nq is the order of the orthogonal matrix Q or P^T that is applied.

If $vect = 'Q'$, $A(ia:*, ja:*)$ is assumed to have been an nq -by- k matrix:

If $nq \geq k$, $Q = H(1) H(2) \dots H(k)$;

If $nq < k$, $Q = H(1) H(2) \dots H(nq-1)$.

If $vect = 'P'$, $A(ia:*, ja:*)$ is assumed to have been a k -by- nq matrix:

If $k < nq$, $P = G(1) G(2) \dots G(k)$;

If $k \geq nq$, $P = G(1) G(2) \dots G(nq-1)$.

Input Parameters

$vect$	(global) If $vect = 'Q'$, then Q or Q^T is applied. If $vect = 'P'$, then P or P^T is applied.
$side$	(global) If $side = 'L'$, then Q or Q^T , P or P^T is applied from the left. If $side = 'R'$, then Q or Q^T , P or P^T is applied from the right.
$trans$	(global) If $trans = 'N'$, no transpose, Q or P is applied. If $trans = 'T'$, then Q^T or P^T is applied.
m	(global) The number of rows in the distributed matrix $\text{sub}(C)$.
n	(global) The number of columns in the distributed matrix $\text{sub}(C)$.
k	(global) If $vect = 'Q'$, the number of columns in the original distributed matrix reduced by p?gebrd ; If $vect = 'P'$, the number of rows in the original distributed matrix reduced by p?gebrd . Constraints: $k \geq 0$.
a	(local)

Pointer into the local memory to an array of size $lld\_a * LOCc(ja + \min(nq, k) - 1)$ if $vect = 'Q'$, and $lld\_a * LOCc(ja + nq - 1)$ if $vect = 'P'$.
 $nq = m$ if $side = 'L'$, and $nq = n$ otherwise.

The vectors that define the elementary reflectors $H(i)$ and $G(i)$, whose products determine the matrices Q and P , as returned by `p?gebrd`.

If $vect = 'Q'$, $lld\_a \geq \max(1, LOCr(ia + nq - 1))$;

If $vect = 'P'$, $lld\_a \geq \max(1, LOCr(ia + \min(nq, k) - 1))$.

ia, ja (global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively.

desca (global and local) array of size $dlen\_$. The array descriptor for the distributed matrix A .

tau (local)
 Array of size $LOCc(ja + \min(nq, k) - 1)$, if $vect = 'Q'$, and $LOCr(ia + \min(nq, k) - 1)$, if $vect = 'P'$.
tau[i] must contain the scalar factor of the elementary reflector $H(i+1)$ or $G(i+1)$
 which determines Q or P , as returned by `pdgebrd` in its array argument *tauq* or *taup*. *tau* is tied to the distributed matrix A .

c (local)
 Pointer into the local memory to an array of size $lld\_c * LOCc(jc + n - 1)$.
 Contains the local pieces of the distributed matrix sub (C).

ic, jc (global) The row and column indices in the global matrix C indicating the first row and the first column of the submatrix C , respectively.

descc (global and local) array of size $dlen\_$. The array descriptor for the distributed matrix C .

work (local)
 Workspace array of size *lwork*.

lwork (local or global) size of *work*, must be at least:

```
If side = 'L'
nq = m;
if ((vect = 'Q' and nq ≥ k) or (vect is not equal to 'Q' and nq > k)),
  iaa=ia; jaa=ja; mi=m; ni=n; icc=ic; jcc=jc;
else
  iaa= ia+1; jaa=ja; mi=m-1; ni=n; icc=ic+1; jcc= jc;
end if
else
If side = 'R', nq = n;
```

```

if((vect = 'Q' and nq>k) or (vect is not equal to 'Q' and
nq>k)),

mqa0 = numroc(mi+icoffa, nb_a, MYCOL, iacol, NPCOL),
npa0 = numroc(ni+iroffa, mb_a, MYROW, iarow, NPROW),
iroffc = mod(icc-1, mb_c),
icoffc = mod(jcc-1, nb_c),
icrow = indxg2p(icc, mb_c, MYROW, rsrc_c, NPROW),
iccol = indxg2p(jcc, nb_c, MYCOL, csrc_c, NPCOL),
mpc0 = numroc(mi+iroffc, mb_c, MYROW, icrow, NPROW),
nqc0 = numroc(ni+icoffc, nb_c, MYCOL, iccol, NPCOL),

```

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

`indxg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the function `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `p?xerbla`.

Output Parameters

<code>c</code>	On exit, if <code>vect='Q'</code> , <code>sub(C)</code> is overwritten by $Q \cdot \text{sub}(C)$, or $Q' \cdot \text{sub}(C)$, or $\text{sub}(C) \cdot Q'$, or $\text{sub}(C) \cdot Q$; if <code>vect='P'</code> , <code>sub(C)</code> is overwritten by $P \cdot \text{sub}(C)$, or $P' \cdot \text{sub}(C)$, or $\text{sub}(C) \cdot P$, or $\text{sub}(C) \cdot P'$.
<code>work[0]</code>	On exit <code>work[0]</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) = 0: the execution is successful. < 0: if the i -th argument is an array and the j -th entry, indexed $j - 1$, had an illegal value, then <code>info</code> = $-(i \cdot 100 + j)$; if the i -th argument is a scalar and had an illegal value, then <code>info</code> = $-i$.

p?unmbr

Multiplies a general matrix by one of the unitary transformation matrices from a reduction to bidiagonal form determined by p?gebrd.

Syntax

```
void pcunmbr (char *vect , char *side , char *trans , MKL_INT *m , MKL_INT *n ,
MKL_INT *k , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca ,
MKL_Complex8 *tau , MKL_Complex8 *c , MKL_INT *ic , MKL_INT *jc , MKL_INT *descc ,
MKL_Complex8 *work , MKL_INT *lwork , MKL_INT *info );

void pzunmbr (char *vect , char *side , char *trans , MKL_INT *m , MKL_INT *n ,
MKL_INT *k , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca ,
MKL_Complex16 *tau , MKL_Complex16 *c , MKL_INT *ic , MKL_INT *jc , MKL_INT *descc ,
MKL_Complex16 *work , MKL_INT *lwork , MKL_INT *info );
```

Include Files

- `mkl_scalapack.h`

Description

If `vect = 'Q'`, the `p?unmbr` function overwrites the general complex distributed m -by- n matrix `sub(C) = C(ic:ic+m-1,jc:jc+n-1)` with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$Q * sub(C)$	$sub(C) * Q$
$trans = 'C':$	$Q^H * sub(C)$	$sub(C) * Q^H$

If $vect = 'P'$, the function overwrites $sub(C)$ with

	$side = 'L'$	$side = 'R'$
$trans = 'N':$	$P * sub(C)$	$sub(C) * P$
$trans = 'C':$	$P^H * sub(C)$	$sub(C) * P^H$

Here Q and P^H are the unitary distributed matrices determined by `p?gebrd` when reducing a complex distributed matrix $A(ia:*, ja:*)$ to bidiagonal form: $A(ia:*, ja:*) = Q * B * P^H$.

Q and P^H are defined as products of elementary reflectors $H(i)$ and $G(i)$ respectively.

Let $nq = m$ if $side = 'L'$ and $nq = n$ if $side = 'R'$. Therefore nq is the order of the unitary matrix Q or P^H that is applied.

If $vect = 'Q'$, $A(ia:*, ja:*)$ is assumed to have been an nq -by- k matrix:

If $nq \geq k$, $Q = H(1) H(2) \dots H(k)$;

If $nq < k$, $Q = H(1) H(2) \dots H(nq-1)$.

If $vect = 'P'$, $A(ia:*, ja:*)$ is assumed to have been a k -by- nq matrix:

If $k < nq$, $P = G(1) G(2) \dots G(k)$;

If $k \geq nq$, $P = G(1) G(2) \dots G(nq-1)$.

Input Parameters

$vect$	(global) If $vect = 'Q'$, then Q or Q^H is applied. If $vect = 'P'$, then P or P^H is applied.
$side$	(global) If $side = 'L'$, then Q or Q^H , P or P^H is applied from the left. If $side = 'R'$, then Q or Q^H , P or P^H is applied from the right.
$trans$	(global) If $trans = 'N'$, no transpose, Q or P is applied. If $trans = 'C'$, conjugate transpose, Q^H or P^H is applied.
m	(global) The number of rows in the distributed matrix $sub(C)$ $m \geq 0$.
n	(global) The number of columns in the distributed matrix $sub(C)$ $n \geq 0$.
k	(global) If $vect = 'Q'$, the number of columns in the original distributed matrix reduced by <code>p?gebrd</code> ; If $vect = 'P'$, the number of rows in the original distributed matrix reduced by <code>p?gebrd</code> . Constraints: $k \geq 0$.

<i>a</i>	(local) Pointer into the local memory to an array of size $lld\_a * LOCc(ja + \min(nq, k) - 1)$ if <i>vect</i> = 'Q', and $lld\_a * LOCc(ja + nq - 1)$ if <i>vect</i> = 'P'. $nq = m$ if <i>side</i> = 'L', and $nq = n$ otherwise. The vectors that define the elementary reflectors $H(i)$ and $G(i)$, whose products determine the matrices Q and P, as returned by <code>p?gebrd</code>. If <i>vect</i> = 'Q', $lld\_a \geq \max(1, LOCr(ia + nq - 1))$; If <i>vect</i> = 'P', $lld\_a \geq \max(1, LOCr(ia + \min(nq, k) - 1))$.
<i>ia, ja</i>	(global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A, respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i>. The array descriptor for the distributed matrix A.
<i>tau</i>	(local) Array of size $LOCc(ja + \min(nq, k) - 1)$, if <i>vect</i> = 'Q', and $LOCr(ia + \min(nq, k) - 1)$, if <i>vect</i> = 'P'. <i>tau</i>[<i>i</i>] must contain the scalar factor of the elementary reflector $H(i+1)$ or $G(i+1)$, which determines Q or P, as returned by <code>p?gebrd</code> in its array argument <i>tauq</i> or <i>taup</i>. <i>tau</i> is tied to the distributed matrix A.
<i>c</i>	(local) Pointer into the local memory to an array of size $lld\_c * LOCc(jc + n - 1)$. Contains the local pieces of the distributed matrix sub (C).
<i>ic, jc</i>	(global) The row and column indices in the global matrix C indicating the first row and the first column of the submatrix C, respectively.
<i>descc</i>	(global and local) array of size <i>dlen_</i>. The array descriptor for the distributed matrix C.
<i>work</i>	(local) Workspace array of size <i>lwork</i>.
<i>lwork</i>	(local or global) size of <i>work</i>, must be at least: If <i>side</i> = 'L' $nq = m$; if ((<i>vect</i> = 'Q' and $nq \geq k$) or (<i>vect</i> is not equal to 'Q' and $nq \geq k$)), $iaa = ia$; $jaa = ja$; $mi = m$; $ni = n$; $icc = ic$; $jcc = jc$; else $iaa = ia + 1$; $jaa = ja$; $mi = m - 1$; $ni = n$; $icc = ic + 1$; $jcc = jc$; end if else If <i>side</i> = 'R', $nq = n$;

Generalized Symmetric-Definite Eigen Problems

This section describes ScaLAPACK routines that allow you to reduce the *generalized symmetric-definite eigenvalue problems* (see [Generalized Symmetric-Definite Eigenvalue Problems](#) in LAPACK chapters) to standard symmetric eigenvalue problem $Cy = \lambda y$, which you can solve by calling ScaLAPACK routines described earlier in this chapter (see [Symmetric Eigenproblems](#)).

Table "Computational Routines for Reducing Generalized Eigenproblems to Standard Problems" lists these routines.

Computational Routines for Reducing Generalized Eigenproblems to Standard Problems

Operation	Real symmetric matrices	Complex Hermitian matrices
Reduce to standard problems	p?sygst	p?hegst

p?sygst

Reduces a real symmetric-definite generalized eigenvalue problem to the standard form.

Syntax

```
void pssygst (MKL_INT *ibtype , char *uplo , MKL_INT *n , float *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , float *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb ,
float *scale , MKL_INT *info );
```

```
void pdsygst (MKL_INT *ibtype , char *uplo , MKL_INT *n , double *a , MKL_INT *ia ,

Description

The `p?sygst` function reduces real symmetric-definite generalized eigenproblems to the standard form.

In the following $\text{sub}(A)$ denotes $A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$ and $\text{sub}(B)$ denotes $B(\text{ib}:\text{ib}+n-1, \text{jb}:\text{jb}+n-1)$.

If $\text{ibtype} = 1$, the problem is

$$\text{sub}(A)*x = \lambda*\text{sub}(B)*x,$$

and $\text{sub}(A)$ is overwritten by $\text{inv}(U^T)*\text{sub}(A)*\text{inv}(U)$, or $\text{inv}(L)*\text{sub}(A)*\text{inv}(L^T)$.

If $\text{ibtype} = 2$ or 3 , the problem is

$$\text{sub}(A)*\text{sub}(B)*x = \lambda*x, \text{ or } \text{sub}(B)*\text{sub}(A)*x = \lambda*x,$$

and $\text{sub}(A)$ is overwritten by $U*\text{sub}(A)*U^T$, or $L^T*\text{sub}(A)*L$.

$\text{sub}(B)$ must have been previously factorized as U^T*U or $L*L^T$ by `p?potrf`.

Input Parameters

<i>ibtype</i>	(global) Must be 1 or 2 or 3. If $\text{itype} = 1$, compute $\text{inv}(U^T)*\text{sub}(A)*\text{inv}(U)$, or $\text{inv}(L)*\text{sub}(A)*\text{inv}(L^T)$; If $\text{itype} = 2$ or 3 , compute $U*\text{sub}(A)*U^T$, or $L^T*\text{sub}(A)*L$.
<i>uplo</i>	(global) Must be 'U' or 'L'. If $\text{uplo} = \text{'U'}$, the upper triangle of $\text{sub}(A)$ is stored and $\text{sub}(B)$ is factored as U^T*U . If $\text{uplo} = \text{'L'}$, the lower triangle of $\text{sub}(A)$ is stored and $\text{sub}(B)$ is factored as $L*L^T$.
<i>n</i>	(global) The order of the matrices $\text{sub}(A)$ and $\text{sub}(B)$ ($n \geq 0$).
<i>a</i>	(local) Pointer into the local memory to an array of size $\text{lld\_a}*\text{LOCc}(\text{ja}+n-1)$. On entry, the array contains the local pieces of the n -by- n symmetric distributed matrix $\text{sub}(A)$. If $\text{uplo} = \text{'U'}$, the leading n -by- n upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced. If $\text{uplo} = \text{'L'}$, the leading n -by- n lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the matrix, and its strictly upper triangular part is not referenced.
<i>ia, ja</i>	(global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively.

<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .
<i>b</i>	(local) Pointer into the local memory to an array of size <i>lld_b*LOCc(jb+n-1)</i> . On entry, the array contains the local pieces of the triangular factor from the Cholesky factorization of sub (<i>B</i>) as returned by <i>p?potrf</i> .
<i>ib, jb</i>	(global) The row and column indices in the global matrix <i>B</i> indicating the first row and the first column of the submatrix <i>B</i> , respectively.
<i>descb</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>B</i> .

Output Parameters

<i>a</i>	On exit, if <i>info</i> = 0, the transformed matrix, stored in the same format as sub(<i>A</i>).
<i>scale</i>	(global) Amount by which the eigenvalues should be scaled to compensate for the scaling performed in this function. At present, <i>scale</i> is always returned as 1.0, it is returned here to allow for future enhancement.
<i>info</i>	(global) If <i>info</i> = 0, the execution is successful. If <i>info</i> < 0, if the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j</i> - 1, had an illegal value, then <i>info</i> = $-(i*100+j)$; if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = $-i$.

p?hegst

Reduces a Hermitian positive-definite generalized eigenvalue problem to the standard form.

Syntax

```
void pchegst (MKL_INT *ibtype , char *uplo , MKL_INT *n , MKL_Complex8 *a , MKL_INT
*ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *b , MKL_INT *ib , MKL_INT *jb ,
MKL_INT *descb , float *scale , MKL_INT *info );
```

```
void pzhegst (MKL_INT *ibtype , char *uplo , MKL_INT *n , MKL_Complex16 *a , MKL_INT
*ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *b , MKL_INT *ib , MKL_INT *jb ,
MKL_INT *descb , double *scale , MKL_INT *info );
```

Include Files

- `mkl_scalapack.h`

Description

The *p?hegst* function reduces complex Hermitian positive-definite generalized eigenproblems to the standard form.

In the following sub(*A*) denotes *A*(*ia:ia+n-1, ja:ja+n-1*) and sub(*B*) denotes *B*(*ib:ib+n-1, jb:jb+n-1*).

If $ibtype = 1$, the problem is

$$\text{sub}(A)*x = \lambda*\text{sub}(B)*x,$$

and $\text{sub}(A)$ is overwritten by $\text{inv}(U^H)*\text{sub}(A)*\text{inv}(U)$, or $\text{inv}(L)*\text{sub}(A)*\text{inv}(L^H)$.

If $ibtype = 2$ or 3 , the problem is

$$\text{sub}(A)*\text{sub}(B)*x = \lambda*x, \text{ or } \text{sub}(B)*\text{sub}(A)*x = \lambda*x,$$

and $\text{sub}(A)$ is overwritten by $U*\text{sub}(A)*U^H$, or $L^H*\text{sub}(A)*L$.

$\text{sub}(B)$ must have been previously factorized as U^H*U or $L*L^H$ by `p?potrf`.

Input Parameters

<i>ibtype</i>	(global) Must be 1 or 2 or 3. If $ibtype = 1$, compute $\text{inv}(U^H)*\text{sub}(A)*\text{inv}(U)$, or $\text{inv}(L)*\text{sub}(A)*\text{inv}(L^H)$; If $ibtype = 2$ or 3 , compute $U*\text{sub}(A)*U^H$, or $L^H*\text{sub}(A)*L$.
<i>uplo</i>	(global) Must be 'U' or 'L'. If $uplo = 'U'$, the upper triangle of $\text{sub}(A)$ is stored and $\text{sub}(B)$ is factored as U^H*U . If $uplo = 'L'$, the lower triangle of $\text{sub}(A)$ is stored and $\text{sub}(B)$ is factored as $L*L^H$.
<i>n</i>	(global) The order of the matrices $\text{sub}(A)$ and $\text{sub}(B)$ ($n \geq 0$).
<i>a</i>	(local) Pointer into the local memory to an array of size $lld\_a*LOCc(ja+n-1)$. On entry, the array contains the local pieces of the n -by- n Hermitian distributed matrix $\text{sub}(A)$. If $uplo = 'U'$, the leading n -by- n upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced. If $uplo = 'L'$, the leading n -by- n lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the matrix, and its strictly upper triangular part is not referenced.
<i>ia, ja</i>	(global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively.
<i>desca</i>	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix A .
<i>b</i>	(local) Pointer into the local memory to an array of size $lld\_b*LOCc(jb+n-1)$. On entry, the array contains the local pieces of the triangular factor from the Cholesky factorization of $\text{sub}(B)$ as returned by <code>p?potrf</code> .
<i>ib, jb</i>	(global) The row and column indices in the global matrix B indicating the first row and the first column of the submatrix B , respectively.
<i>descb</i>	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix B .

Output Parameters

<i>a</i>	On exit, if <i>info</i> = 0, the transformed matrix, stored in the same format as sub(A).
<i>scale</i>	(global) Amount by which the eigenvalues should be scaled to compensate for the scaling performed in this function. At present, <i>scale</i> is always returned as 1.0, it is returned here to allow for future enhancement.
<i>info</i>	(global) If <i>info</i> = 0, the execution is successful. If <i>info</i> < 0, if the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j</i> - 1, had an illegal value, then <i>info</i> = $-(i*100+j)$; if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

Driver Routines

Table "ScaLAPACK Driver Routines" lists ScaLAPACK driver routines available for solving systems of linear equations, linear least-squares problems, standard eigenvalue and singular value problems, and generalized symmetric definite eigenproblems.

ScaLAPACK Driver Routines

Type of Problem	Matrix type, storage scheme	Driver
Linear equations	general (partial pivoting)	p?gesv (simple driver) / p?gesvx (expert driver)
	general band (partial pivoting)	p?gbsv (simple driver)
	general band (no pivoting)	p?dbsv (simple driver)
	general tridiagonal (no pivoting)	p?dtsv (simple driver)
	symmetric/Hermitian positive-definite	p?posv (simple driver) / p?posvx (expert driver)
	symmetric/Hermitian positive-definite, band	p?pbsv (simple driver)
	symmetric/Hermitian positive-definite, tridiagonal	p?ptsv (simple driver)
Linear least squares problem	general <i>m</i> -by- <i>n</i>	p?gels
Symmetric eigenvalue problem	symmetric/Hermitian	p?syev / p?heev (simple driver); p?syevd / p?heevd (simple driver with a divide and conquer algorithm); p?syevx / p?heevx (expert driver); p?syevr / p?heevr (simple driver with MRRR algorithm)
Singular value decomposition	general <i>m</i> -by- <i>n</i>	p?gesvd
Generalized symmetric definite eigenvalue problem	symmetric/Hermitian, one matrix also positive-definite	p?sygvx / p?hegvx (expert driver)

p?gesv

Computes the solution to the system of linear equations with a square distributed matrix and multiple right-hand sides.

Syntax

```
void psgesv (MKL_INT *n , MKL_INT *nrhs , float *a , MKL_INT *ia , MKL_INT *ja ,

Description

The `p?gesv` function computes the solution to a real or complex system of linear equations $\text{sub}(A) * X = \text{sub}(B)$, where $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$ is an n -by- n distributed matrix and X and $\text{sub}(B) = B(\text{ib}:\text{ib}+n-1, \text{jb}:\text{jb}+nrhs-1)$ are n -by- $nrhs$ distributed matrices.

The LU decomposition with partial pivoting and row interchanges is used to factor $\text{sub}(A)$ as $\text{sub}(A) = P * L * U$, where P is a permutation matrix, L is unit lower triangular, and U is upper triangular. L and U are stored in $\text{sub}(A)$. The factored form of $\text{sub}(A)$ is then used to solve the system of equations $\text{sub}(A) * X = \text{sub}(B)$.

Input Parameters

<i>n</i>	(global) The number of rows and columns to be operated on, that is, the order of the distributed submatrix $\text{sub}(A)$ ($n \geq 0$).
<i>nrhs</i>	(global) The number of right hand sides, that is, the number of columns of the distributed submatrices B and X ($nrhs \geq 0$).
<i>a, b</i>	(local) Pointers into the local memory to arrays of local size <i>a</i> : <code>lld_a*LOCc(ja+n-1)</code> and <i>b</i> : <code>lld_b*LOCc(jb+nrhs-1)</code> , respectively. On entry, the array <i>a</i> contains the local pieces of the n -by- n distributed matrix $\text{sub}(A)$ to be factored. On entry, the array <i>b</i> contains the right hand side distributed matrix $\text{sub}(B)$.
<i>ia, ja</i>	(global) The row and column indices in the global matrix A indicating the first row and the first column of $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix A .
<i>ib, jb</i>	(global) The row and column indices in the global matrix B indicating the first row and the first column of $\text{sub}(B)$, respectively.

descb (global and local) array of size *dlen_*. The array descriptor for the distributed matrix *B*.

Output Parameters

a Overwritten by the factors *L* and *U* from the factorization $\text{sub}(A) = P * L * U$; the unit diagonal elements of *L* are not stored .

b Overwritten by the solution distributed matrix *X*.

ipiv (local) Array of size $LOCr(m\_a) + mb\_a$. This array contains the pivoting information. The (local) row *i* of the matrix was interchanged with the (global) row *ipiv*[*i* - 1].

This array is tied to the distributed matrix *A*.

info (global) If *info*=0, the execution is successful.

info < 0:

If the *i*-th argument is an array and the *j*-th entry had an illegal value, then *info* = -(*i**100+*j*); if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

info > 0:

If *info* = *k*, *U*(*ia*+*k*-1,*ja*+*k*-1) is exactly zero. The factorization has been completed, but the factor *U* is exactly singular, so the solution could not be computed.

Description

The `p?gesvx` function uses the *LU* factorization to compute the solution to a real or complex system of linear equations $AX = B$, where A denotes the n -by- n submatrix $A(ia:ia+n-1, ja:ja+n-1)$, B denotes the n -by- $nrhs$ submatrix $B(ib:ib+n-1, jb:jb+nrhs-1)$ and X denotes the n -by- $nrhs$ submatrix $X(ix:ix+n-1, jx:jx+nrhs-1)$.

Error bounds on the solution and a condition estimate are also provided.

In the following description, *af* stands for the subarray of *af* from row *iaf* and column *jaf* to row *iaf*+ n -1 and column *jaf*+ n -1.

The function `p?gesvx` performs the following steps:

1. If *fact* = 'E', real scaling factors R and C are computed to equilibrate the system:

```

trans = 'N': diag(R)*A*diag(C) *diag(C)-1*X = diag(R)*B
trans = 'T': (diag(R)*A*diag(C))T *diag(R)-1*X = diag(C)*B
trans = 'C': (diag(R)*A*diag(C))H *diag(R)-1*X = diag(C)*B

```

Whether or not the system will be equilibrated depends on the scaling of the matrix A , but if equilibration is used, A is overwritten by $\text{diag}(R) * A * \text{diag}(C)$ and B by $\text{diag}(R) * B$ (if *trans*='N') or $\text{diag}(C) * B$ (if *trans* = 'T' or 'C').

2. If *fact* = 'N' or 'E', the *LU* decomposition is used to factor the matrix A (after equilibration if *fact* = 'E') as $A = PLU$, where P is a permutation matrix, L is a unit lower triangular matrix, and U is upper triangular.
3. The factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than relative machine precision, steps 4 - 6 are skipped.
4. The system of equations is solved for X using the factored form of A .
5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.
6. If equilibration was used, the matrix X is premultiplied by $\text{diag}(C)$ (if *trans* = 'N') or $\text{diag}(R)$ (if *trans* = 'T' or 'C') so that it solves the original system before equilibration.

Input Parameters

fact (global) Must be 'F', 'N', or 'E'.

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored.

If $fact = 'F'$ then, on entry, af and $ipiv$ contain the factored form of A . If $equed$ is not $'N'$, the matrix A has been equilibrated with scaling factors given by r and c . Arrays a , af , and $ipiv$ are not modified.

If $fact = 'N'$, the matrix A is copied to af and factored.

If $fact = 'E'$, the matrix A is equilibrated if necessary, then copied to af and factored.

$trans$

(global) Must be $'N'$, $'T'$, or $'C'$.

Specifies the form of the system of equations:

If $trans = 'N'$, the system has the form $A*X = B$ (No transpose);

If $trans = 'T'$, the system has the form $A^T*X = B$ (Transpose);

If $trans = 'C'$, the system has the form $A^H*X = B$ (Conjugate transpose);

n

(global) The number of linear equations; the order of the submatrix A ($n \geq 0$).

$nrhs$

(global) The number of right hand sides; the number of columns of the distributed submatrices B and X ($nrhs \geq 0$).

$a, af, b, work$

(local)

Pointers into the local memory to arrays of local size a : $lld\_a*LOCc(ja+n-1)$, af : $lld\_af*LOCc(ja+n-1)$, b : $lld\_b*LOCc(jb+nrhs-1)$, $work$: $lwork$.

The array a contains the matrix A . If $fact = 'F'$ and $equed$ is not $'N'$, then A must have been equilibrated by the scaling factors in r and/or c .

The array af is an input argument if $fact = 'F'$. In this case it contains on entry the factored form of the matrix A , that is, the factors L and U from the factorization $A = P*L*U$ as computed by [p?getrf](#). If $equed$ is not $'N'$, then af is the factored form of the equilibrated matrix A .

The array b contains on entry the matrix B whose columns are the right-hand sides for the systems of equations.

$work$ is a workspace array. The size of $work$ is ($lwork$).

ia, ja

(global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix $A(ia:ia+n-1, ja:ja+n-1)$, respectively.

$desca$

(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix A .

iaf, jaf

(global) The row and column indices in the global matrix AF indicating the first row and the first column of the subarray af , respectively.

$descaf$

(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix AF .

ib, jb

(global) The row and column indices in the global matrix B indicating the first row and the first column of the submatrix $B(ib:ib+n-1, jb:jb+nrhs-1)$, respectively.

<i>descb</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>B</i> .
<i>ipiv</i>	(local) Array of size $LOCr(m\_a)+mb\_a$. The array <i>ipiv</i> is an input argument if <i>fact</i> = 'F'. On entry, it contains the pivot indices from the factorization $A = P*L*U$ as computed by <code>p?getrf</code>; (local) row <i>i</i> of the matrix was interchanged with the (global) row <i>ipiv</i>[<i>i</i> - 1]. This array must be aligned with $A(ia:ia+n-1, *)$.
<i>equed</i>	(global) Must be 'N', 'R', 'C', or 'B'. <i>equed</i> is an input argument if <i>fact</i> = 'F'. It specifies the form of equilibration that was done: If <i>equed</i> = 'N', no equilibration was done (always true if <i>fact</i> = 'N'); If <i>equed</i> = 'R', row equilibration was done, that is, <i>A</i> has been premultiplied by $diag(r)$; If <i>equed</i> = 'C', column equilibration was done, that is, <i>A</i> has been postmultiplied by $diag(c)$; If <i>equed</i> = 'B', both row and column equilibration was done; <i>A</i> has been replaced by $diag(r)*A*diag(c)$.
<i>r, c</i>	(local) Arrays of size $LOCr(m\_a)$ and $LOCc(n\_a)$, respectively. The array <i>r</i> contains the row scale factors for <i>A</i>, and the array <i>c</i> contains the column scale factors for <i>A</i>. These arrays are input arguments if <i>fact</i> = 'F' only; otherwise they are output arguments. If <i>equed</i> = 'R' or 'B', <i>A</i> is multiplied on the left by $diag(r)$; if <i>equed</i> = 'N' or 'C', <i>r</i> is not accessed. If <i>fact</i> = 'F' and <i>equed</i> = 'R' or 'B', each element of <i>r</i> must be positive. If <i>equed</i> = 'C' or 'B', <i>A</i> is multiplied on the right by $diag(c)$; if <i>equed</i> = 'N' or 'R', <i>c</i> is not accessed. If <i>fact</i> = 'F' and <i>equed</i> = 'C' or 'B', each element of <i>c</i> must be positive. Array <i>r</i> is replicated in every process column, and is aligned with the distributed matrix <i>A</i>. Array <i>c</i> is replicated in every process row, and is aligned with the distributed matrix <i>A</i>.
<i>ix, jx</i>	(global) The row and column indices in the global matrix <i>X</i> indicating the first row and the first column of the submatrix $X(ix:ix+n-1, jx:jx+nrhs-1)$, respectively.
<i>descx</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>X</i> .
<i>lwork</i>	(local or global) The size of the array <i>work</i> ; must be at least $\max(p?gecon(lwork), p?gerfs(lwork))+LOCr(n\_a)$.
<i>iwork</i>	(local, <code>psgesvx</code> / <code>pdgesvx</code> only). Workspace array. The size of <i>iwork</i> is (<i>liwork</i>).

<i>liwork</i>	(local, psgesvx/pdgesvx only). The size of the array <i>iwork</i> , must be at least $LOCr(n_a)$.
<i>rwork</i>	(local) Workspace array, used in complex flavors only. The size of <i>rwork</i> is (<i>lrwork</i>).
<i>lrwork</i>	(local or global, pcgesvx/pzgesvx only). The size of the array <i>rwork</i> ; must be at least $2*LOCc(n_a)$.

Output Parameters

<i>x</i>	(local) Pointer into the local memory to an array of local size $l1d\_x*LOCc(jx + nrhs - 1)$. If <i>info</i> = 0, the array <i>x</i> contains the solution matrix <i>X</i> to the <i>original</i> system of equations. Note that <i>A</i> and <i>B</i> are modified on exit if <i>equed</i> ≠ 'N', and the solution to the <i>equilibrated</i> system is: $diag(C) \cdot 1 \cdot X$, if <i>trans</i> = 'N' and <i>equed</i> = 'C' or 'B'; and $diag(R) \cdot 1 \cdot X$, if <i>trans</i> = 'T' or 'C' and <i>equed</i> = 'R' or 'B'.
<i>a</i>	Array <i>a</i> is not modified on exit if <i>fact</i> = 'F' or 'N', or if <i>fact</i> = 'E' and <i>equed</i> = 'N'. If <i>equed</i> ≠ 'N', <i>A</i> is scaled on exit as follows: <i>equed</i> = 'R': $A = diag(R) \cdot A$ <i>equed</i> = 'C': $A = A \cdot diag(c)$ <i>equed</i> = 'B': $A = diag(R) \cdot A \cdot diag(c)$
<i>af</i>	If <i>fact</i> = 'N' or 'E', then <i>af</i> is an output argument and on exit returns the factors <i>L</i> and <i>U</i> from the factorization $A = P \cdot L \cdot U$ of the original matrix <i>A</i> (if <i>fact</i> = 'N') or of the equilibrated matrix <i>A</i> (if <i>fact</i> = 'E'). See the description of <i>a</i> for the form of the equilibrated matrix.
<i>b</i>	Overwritten by $diag(R) \cdot B$ if <i>trans</i> = 'N' and <i>equed</i> = 'R' or 'B'; overwritten by $diag(c) \cdot B$ if <i>trans</i> = 'T' and <i>equed</i> = 'C' or 'B'; not changed if <i>equed</i> = 'N'.
<i>r, c</i>	These arrays are output arguments if <i>fact</i> ≠ 'F'. See the description of <i>r, c</i> in <i>Input Arguments</i> section.
<i>rcond</i>	(global). An estimate of the reciprocal condition number of the matrix <i>A</i> after equilibration (if done). The function sets <i>rcond</i> = 0 if the estimate underflows; in this case the matrix is singular (to working precision). However, anytime <i>rcond</i> is small compared to 1.0, for the working precision, the matrix may be poorly conditioned or even singular.
<i>ferr, berr</i>	(local)

Arrays of size $LOCc(n\_b)$ each. Contain the component-wise forward and relative backward errors, respectively, for each solution vector.

Arrays *ferr* and *berr* are both replicated in every process row, and are aligned with the matrices *B* and *X*.

<i>ipiv</i>	If <i>fact</i> = 'N' or 'E', then <i>ipiv</i> is an output argument and on exit contains the pivot indices from the factorization $A = P*L*U$ of the original matrix <i>A</i> (if <i>fact</i> = 'N') or of the equilibrated matrix <i>A</i> (if <i>fact</i> = 'E').
<i>equed</i>	If <i>fact</i> ≠ 'F', then <i>equed</i> is an output argument. It specifies the form of equilibration that was done (see the description of <i>equed</i> in <i>Input Arguments</i> section).
<i>work</i> [0]	If <i>info</i> =0, on exit <i>work</i> [0] returns the minimum value of <i>lwork</i> required for optimum performance.
<i>iwork</i> [0]	If <i>info</i> =0, on exit <i>iwork</i> [0] returns the minimum value of <i>liwork</i> required for optimum performance.
<i>rwork</i> [0]	If <i>info</i> =0, on exit <i>rwork</i> [0] returns the minimum value of <i>lrwork</i> required for optimum performance.
<i>info</i>	If <i>info</i> =0, the execution is successful. <i>info</i> < 0: if the <i>i</i> th argument is an array and the <i>j</i> th entry had an illegal value, then <i>info</i> = $-(i*100+j)$; if the <i>i</i> th argument is a scalar and had an illegal value, then <i>info</i> = $-i$. If <i>info</i> = <i>i</i> , and $i \leq n$, then $U(i,i)$ is exactly zero. The factorization has been completed, but the factor <i>U</i> is exactly singular, so the solution and error bounds could not be computed. If <i>info</i> = <i>i</i> , and $i = n + 1$, then <i>U</i> is nonsingular, but <i>rcond</i> is less than machine precision. The factorization has been completed, but the matrix is singular to working precision and the solution and error bounds have not been computed.

Description

The pzgbsv function computes the solution to a real or complex system of linear equations

$\text{sub}(A) * X = \text{sub}(B)$,

where $\text{sub}(A) = A(1:n, ja:ja+n-1)$ is an n -by- n real/complex general banded distributed matrix with bwl subdiagonals and bwu superdiagonals, and X and $\text{sub}(B) = B(ib:ib+n-1, 1:rhs)$ are n -by- $nrhs$ distributed matrices.

The LU decomposition with partial pivoting and row interchanges is used to factor $\text{sub}(A)$ as $\text{sub}(A) = P * L * U * Q$, where P and Q are permutation matrices, and L and U are banded lower and upper triangular matrices, respectively. The matrix Q represents reordering of columns for the sake of parallelism, while P represents reordering of rows for numerical stability using classic partial pivoting.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

n	(global) The number of rows and columns to be operated on, that is, the order of the distributed matrix $\text{sub}(A)$ ($n \geq 0$).
bwl	(global) The number of subdiagonals within the band of A ($0 \leq bwl \leq n-1$).
bwu	(global) The number of superdiagonals within the band of A ($0 \leq bwu \leq n-1$).
$nrhs$	(global) The number of right hand sides; the number of columns of the distributed matrix $\text{sub}(B)$ ($nrhs \geq 0$).
a, b	(local) Pointers into the local memory to arrays of local size a : $lld\_a * LOCC(ja + n - 1)$ and b : $lld\_b * LOCC(nrhs)$. On entry, the array a contains the local pieces of the global array A . On entry, the array b contains the right hand side distributed matrix $\text{sub}(B)$.
ja	(global) The index in the global matrix A indicating the start of the matrix to be operated on (which may be either all of A or a submatrix of A).

<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> . If <i>desca</i> [<i>dtype_</i> - 1] = 501, then <i>dlen_</i> ≥ 7; else if <i>desca</i> [<i>dtype_</i> - 1] = 1, then <i>dlen_</i> ≥ 9.
<i>ib</i>	(global) The row index in the global matrix <i>B</i> indicating the first row of the matrix to be operated on (which may be either all of <i>B</i> or a submatrix of <i>B</i>).
<i>descb</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>B</i> . If <i>descb</i> [<i>dtype_-</i> 1] = 502, then <i>dlen_</i> ≥ 7; else if <i>descb</i> [<i>dtype_-</i> 1] = 1, then <i>dlen_</i> ≥ 9.
<i>work</i>	(local) Workspace array of size <i>lwork</i> .
<i>lwork</i>	(local or global) The size of the array <i>work</i> , must be at least $lwork \geq (NB + bwu) * (bwl + bwu) + 6 * (bwl + bwu) * (bwl + 2 * bwu) + \max(nrhs * (NB + 2 * bwl + 4 * bwu), 1)$.

Output Parameters

<i>a</i>	On exit, contains details of the factorization. Note that the resulting factorization is not the same factorization as returned from LAPACK. Additional permutations are performed on the matrix for the sake of parallelism.
<i>b</i>	On exit, this array contains the local pieces of the solution distributed matrix <i>X</i> .
<i>ipiv</i>	(local) array. The size of <i>ipiv</i> must be at least <i>desca</i> [NB - 1]. This array contains pivot indices for local factorizations. You should not alter the contents between factorization and solve.
<i>work</i> [0]	On exit, <i>work</i> [0] contains the minimum value of <i>lwork</i> required for optimum performance.
<i>info</i>	If <i>info</i> =0, the execution is successful. <i>info</i> < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -th entry had an illegal value, then <i>info</i> = -(<i>i</i> *100+ <i>j</i>); if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> . <i>info</i> > 0: If <i>info</i> = <i>k</i> ≤ NPROCS, the submatrix stored on processor <i>info</i> and factored locally was not nonsingular, and the factorization was not completed. If <i>info</i> = <i>k</i> > NPROCS, the submatrix stored on processor <i>info</i> -NPROCS representing interactions with other processors was not nonsingular, and the factorization was not completed.

Description

The p?dbsv function solves the following system of linear equations:

$$A(1:n, ja:ja+n-1) * X = B(ib:ib+n-1, 1:nrhs),$$

where $A(1:n, ja:ja+n-1)$ is an n -by- n real/complex banded diagonally dominant-like distributed matrix with bandwidth bwl , bwu .

Gaussian elimination without pivoting is used to factor a reordering of the matrix into LU .

Notice revision #20110804

Input Parameters

- n (global) The order of the distributed submatrix A , ($n \geq 0$).
- bwl (global) Number of subdiagonals. $0 \leq bwl \leq n-1$.
- bwu (global) Number of subdiagonals. $0 \leq bwu \leq n-1$.

<i>nrhs</i>	(global) The number of right-hand sides; the number of columns of the distributed submatrix B , ($nrhs \geq 0$).
<i>a</i>	(local). Pointer into the local memory to an array with leading size $lld\_a \geq (bwl + bwu + 1)$ (stored in <i>desca</i>). On entry, this array contains the local pieces of the distributed matrix.
<i>ja</i>	(global) The index in the global matrix A indicating the start of the matrix to be operated on (which may be either all of A or a submatrix of A).
<i>desca</i>	(global and local) array of size <i>dlen</i> . If 1d type (<i>dtype_a</i> =501 or 502), $dlen \geq 7$; If 2d type (<i>dtype_a</i> =1), $dlen \geq 9$. The array descriptor for the distributed matrix A . Contains information of mapping of A to memory.
<i>b</i>	(local) Pointer into the local memory to an array of local lead size $lld\_b \geq nb$. On entry, this array contains the local pieces of the right hand sides $B(ib:ib + n - 1, 1:nrhs)$.
<i>ib</i>	(global) The row index in the global matrix B indicating the first row of the matrix to be operated on (which may be either all of b or a submatrix of B).
<i>descb</i>	(global and local) array of size <i>dlen</i> . If 1d type (<i>dtype_b</i> = 502), $dlen \geq 7$; If 2d type (<i>dtype_b</i> = 1), $dlen \geq 9$. The array descriptor for the distributed matrix B . Contains information of mapping of B to memory.
<i>work</i>	(local). Temporary workspace. This space may be overwritten in between calls to functions. <i>work</i> must be the size given in <i>lwork</i> .
<i>lwork</i>	(local or global) Size of user-input workspace <i>work</i> . If <i>lwork</i> is too small, the minimal acceptable size will be returned in <i>work</i> [0] and an error code is returned. $lwork \geq nb(bwl + bwu) + 6 \max(bwl, bwu) * \max(bwl, bwu) + \max((\max(bwl, bwu) nrhs), \max(bwl, bwu) * \max(bwl, bwu))$

Output Parameters

<i>a</i>	On exit, this array contains information containing details of the factorization. Note that permutations are performed on the matrix, so that the factors returned are different from those returned by LAPACK.
<i>b</i>	On exit, this contains the local piece of the solutions distributed matrix X .

work On exit, *work*[0] contains the minimal *lwork*.

info (local) If *info*=0, the execution is successful.

< 0: If the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = -(*i**100+*j*), if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

> 0: If *info* = *k* < NPROCS, the submatrix stored on processor *info* and factored locally was not positive definite, and the factorization was not completed.

If *info* = *k* > NPROCS, the submatrix stored on processor *info*-NPROCS representing interactions with other processors was not positive definite, and the factorization was not completed.

Description

The function solves a system of linear equations

$$A(1:n, ja:ja+n-1) * X = B(ib:ib+n-1, 1:nrhs),$$

where $A(1:n, ja:ja+n-1)$ is an n -by- n complex tridiagonal diagonally dominant-like distributed matrix.

Gaussian elimination without pivoting is used to factor a reordering of the matrix into $L U$.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

<i>n</i>	(global) The order of the distributed submatrix A ($n \geq 0$).
<i>nrhs</i>	The number of right hand sides; the number of columns of the distributed matrix B ($nrhs \geq 0$).
<i>dl</i>	(local). Pointer to local part of global vector storing the lower diagonal of the matrix. Globally, $dl[0]$ is not referenced, and dl must be aligned with d . Must be of size $> desca[nb\_ - 1]$.
<i>d</i>	(local). Pointer to local part of global vector storing the main diagonal of the matrix.
<i>du</i>	(local). Pointer to local part of global vector storing the upper diagonal of the matrix. Globally, $du[n - 1]$ is not referenced, and du must be aligned with d .
<i>ja</i>	(global) The index in the global matrix A indicating the start of the matrix to be operated on (which may be either all of A or a submatrix of A).
<i>desca</i>	(global and local) array of size $dlen$. If 1d type ($dtype\_a=501$ or 502), $dlen \geq 7$; If 2d type ($dtype\_a=1$), $dlen \geq 9$. The array descriptor for the distributed matrix A . Contains information of mapping of A to memory.
<i>b</i>	(local) Pointer into the local memory to an array of local lead size $lld\_b > nb$. On entry, this array contains the local pieces of the right hand sides $B(ib:ib + n - 1, 1:nrhs)$.
<i>ib</i>	(global) The row index in the global matrix B indicating the first row of the matrix to be operated on (which may be either all of b or a submatrix of B).
<i>descb</i>	(global and local) array of size $dlen$. If 1d type ($dtype\_b = 502$), $dlen \geq 7$;

If 2d type (*dtype_b* =1), *dlen* ≥ 9.

The array descriptor for the distributed matrix *B*.

Contains information of mapping of *B* to memory.

work (local).

lwork (local or global) Size of user-input workspace *work*. If *lwork* is too small, the minimal acceptable size will be returned in *work*[0] and an error code is returned. *lwork* > (12*NPCOL+3*nb)+max((10+2*min(100, nrhs))*NPCOL+4*nrhs, 8*NPCOL)

Output Parameters

dl On exit, this array contains information containing the * factors of the matrix.

d On exit, this array contains information containing the * factors of the matrix. Must be of size > *desca*[*nb* - 1].

du On exit, this array contains information containing the * factors of the matrix. Must be of size > *desca*[*nb* - 1].

b On exit, this contains the local piece of the solutions distributed matrix *X*.

work On exit, *work*[0] contains the minimal *lwork*.

info (local) If *info*=0, the execution is successful.
 < 0: If the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = -(*i**100+*j*), if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.
 > 0: If *info* = *k* < NPROCS, the submatrix stored on processor *info* and factored locally was not positive definite, and the factorization was not completed.
 If *info* = *k* > NPROCS, the submatrix stored on processor *info*-NPROCS representing interactions with other processors was not positive definite, and the factorization was not completed.

*descb , MKL_INT *info );

```

Include Files

- mkl_scalapack.h

Description

The `p?posv` function computes the solution to a real/complex system of linear equations

$$\text{sub}(A) * X = \text{sub}(B),$$

where $\text{sub}(A)$ denotes $A(ia:ia+n-1, ja:ja+n-1)$ and is an n -by- n symmetric/Hermitian distributed positive definite matrix and X and $\text{sub}(B)$ denoting $B(ib:ib+n-1, jb:jb+nrhs-1)$ are n -by- $nrhs$ distributed matrices. The Cholesky decomposition is used to factor $\text{sub}(A)$ as

$$\text{sub}(A) = U^T * U, \text{ if } uplo = 'U', \text{ or}$$

$$\text{sub}(A) = L * L^T, \text{ if } uplo = 'L',$$

where U is an upper triangular matrix and L is a lower triangular matrix. The factored form of $\text{sub}(A)$ is then used to solve the system of equations.

Input Parameters

<i>uplo</i>	(global) Must be 'U' or 'L'. Indicates whether the upper or lower triangular part of $\text{sub}(A)$ is stored.
<i>n</i>	(global) The order of the distributed matrix $\text{sub}(A)$ ($n \geq 0$).
<i>nrhs</i>	The number of right-hand sides; the number of columns of the distributed matrix $\text{sub}(B)$ ($nrhs \geq 0$).
<i>a</i>	(local) Pointer into the local memory to an array of size $lld\_a * LOCc(ja+n-1)$. On entry, this array contains the local pieces of the n -by- n symmetric distributed matrix $\text{sub}(A)$ to be factored. If $uplo = 'U'$, the leading n -by- n upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced. If $uplo = 'L'$, the leading n -by- n lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the distributed matrix, and its strictly upper triangular part is not referenced.
<i>ia, ja</i>	(global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively.
<i>desca</i>	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix A .
<i>b</i>	(local)

Pointer into the local memory to an array of size $lld\_b * LOCc(jb + nrhs - 1)$.
On entry, the local pieces of the right hand sides distributed matrix $sub(B)$.

ib, jb

(global) The row and column indices in the global matrix B indicating the first row and the first column of the submatrix B , respectively.

descb

(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix B .

Output Parameters

a

On exit, if *info* = 0, this array contains the local pieces of the factor U or L from the Cholesky factorization $sub(A) = U^H * U$, or $L * L^H$.

b

On exit, if *info* = 0, $sub(B)$ is overwritten by the solution distributed matrix X .

info

(global)

If *info* = 0, the execution is successful.

If *info* < 0: If the *i*-th argument is an array and the *j*-th entry, indexed *j*-1, had an illegal value, then *info* = $-(i * 100 + j)$, if the *i*-th argument is a scalar and had an illegal value, then *info* = $-i$.

If *info* > 0: If *info* = *k*, the leading minor of order *k*, $A(ia:ia+k-1, ja:ja+k-1)$ is not positive definite, and the factorization could not be completed, and the solution has not been computed.

Include Files

- mkl_scalapack.h

Description

The pzposvx function uses the Cholesky factorization $A=U^T*U$ or $A=L*L^T$ to compute the solution to a real or complex system of linear equations

$A(ia:ia+n-1, ja:ja+n-1)*X = B(ib:ib+n-1, jb:jb+nrhs-1)$,

where $A(ia:ia+n-1, ja:ja+n-1)$ is a n -by- n matrix and X and $B(ib:ib+n-1, jb:jb+nrhs-1)$ are n -by- $nrhs$ matrices.

Error bounds on the solution and a condition estimate are also provided.

In the following comments y denotes $Y(iy:iy+m-1, jy:jy+k-1)$, an m -by- k matrix where y can be a, af, b and x .

The function pzposvx performs the following steps:

1. If $fact = 'E'$, real scaling factors s are computed to equilibrate the system:

$diag(sr)*A*diag(sc)*inv(diag(sc))*X = diag(sr)*B$

Whether or not the system will be equilibrated depends on the scaling of the matrix A , but if equilibration is used, A is overwritten by $diag(sr)*A*diag(sc)$ and B by $diag(sr)*B$.

2. If $fact = 'N'$ or $'E'$, the Cholesky decomposition is used to factor the matrix A (after equilibration if $fact = 'E'$) as

$A = U^T*U$, if $uplo = 'U'$, or

$A = L*L^T$, if $uplo = 'L'$,

where U is an upper triangular matrix and L is a lower triangular matrix.

3. The factored form of A is used to estimate the condition number of the matrix A . If the reciprocal of the condition number is less than machine precision, steps 4-6 are skipped
4. The system of equations is solved for X using the factored form of A .
5. Iterative refinement is applied to improve the computed solution matrix and calculate error bounds and backward error estimates for it.
6. If equilibration was used, the matrix X is premultiplied by $diag(sr)$ so that it solves the original system before equilibration.

Input Parameters

fact (global) Must be 'F', 'N', or 'E'.

Specifies whether or not the factored form of the matrix A is supplied on entry, and if not, whether the matrix A should be equilibrated before it is factored.

	If $fact = 'F'$: on entry, af contains the factored form of A. If $equed = 'Y'$, the matrix A has been equilibrated with scaling factors given by s. a and af will not be modified. If $fact = 'N'$, the matrix A will be copied to af and factored. If $fact = 'E'$, the matrix A will be equilibrated if necessary, then copied to af and factored.
$uplo$	(global) Must be $'U'$ or $'L'$. Indicates whether the upper or lower triangular part of A is stored.
n	(global) The order of the distributed matrix $sub(A)$ ($n \geq 0$).
$nrhs$	(global) The number of right-hand sides; the number of columns of the distributed submatrices B and X . ($nrhs \geq 0$).
a	(local) Pointer into the local memory to an array of local size $lld\_a * LOCC(ja + n - 1)$. On entry, the symmetric/Hermitian matrix A, except if $fact = 'F'$ and $equed = 'Y'$, then A must contain the equilibrated matrix $diag(sr) * A * diag(sc)$. If $uplo = 'U'$, the leading n-by-n upper triangular part of A contains the upper triangular part of the matrix A, and the strictly lower triangular part of A is not referenced. If $uplo = 'L'$, the leading n-by-n lower triangular part of A contains the lower triangular part of the matrix A, and the strictly upper triangular part of A is not referenced. A is not modified if $fact = 'F'$ or $'N'$, or if $fact = 'E'$ and $equed = 'N'$ on exit.
ia, ja	(global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively.
$desca$	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix A .
af	(local) Pointer into the local memory to an array of local size $lld\_af * LOCC(ja + n - 1)$. If $fact = 'F'$, then af is an input argument and on entry contains the triangular factor U or L from the Cholesky factorization $A = U^T * U$ or $A = L * L^T$, in the same storage format as A. If $equed \neq 'N'$, then af is the factored form of the equilibrated matrix $diag(sr) * A * diag(sc)$.
iaf, jaf	(global) The row and column indices in the global matrix AF indicating the first row and the first column of the submatrix AF , respectively.
$descaf$	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix AF .
$equed$	(global) Must be $'N'$ or $'Y'$. $equed$ is an input argument if $fact = 'F'$. It specifies the form of equilibration that was done:

If *equed* = 'N', no equilibration was done (always true if *fact* = 'N');

If *equed* = 'Y', equilibration was done and *A* has been replaced by $\text{diag}(sr) * A * \text{diag}(sc)$.

sr

(local)

Array of size *lld_a*.

The array *s* contains the scale factors for *A*. This array is an input argument if *fact* = 'F' only; otherwise it is an output argument.

If *equed* = 'N', *s* is not accessed.

If *fact* = 'F' and *equed* = 'Y', each element of *s* must be positive.

b

(local)

Pointer into the local memory to an array of local size $\text{lld}_b * \text{LOCc}(jb + nrhs - 1)$. On entry, the *n*-by-*nrhs* right-hand side matrix *B*.

ib, jb

(global) The row and column indices in the global matrix *B* indicating the first row and the first column of the submatrix *B*, respectively.

descb

(global and local) Array of size *dlen_*. The array descriptor for the distributed matrix *B*.

x

(local)

Pointer into the local memory to an array of local size $\text{lld}_x * \text{LOCc}(jx + nrhs - 1)$.

ix, jx

(global) The row and column indices in the global matrix *X* indicating the first row and the first column of the submatrix *X*, respectively.

descx

(global and local) array of size *dlen_*. The array descriptor for the distributed matrix *X*.

work

(local)

Workspace array of size *lwork*.

lwork

(local or global)

The size of the array *work*. *lwork* is local input and must be at least $\text{lwork} = \max(\text{p?pocon}(\text{lwork}), \text{p?porfs}(\text{lwork})) + \text{LOCr}(n_a)$.

$\text{lwork} = 3 * \text{desca}[\text{lld}_ - 1]$.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by *pxerbla*.

iwork

(local) Workspace array of size *liwork*.

liwork

(local or global)

The size of the array *iwork*. *liwork* is local input and must be at least $\text{liwork} = \text{desca}[\text{lld}_ - 1] \text{liwork} = \text{LOCr}(n_a)$.

If $liwork = -1$, then $liwork$ is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

a	On exit, if $fact = 'E'$ and $equed = 'Y'$, a is overwritten by $diag(sr) * a * diag(sc)$.
af	If $fact = 'N'$, then af is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization $A = U^T * U$ or $A = L * L^T$ of the original matrix A. If $fact = 'E'$, then af is an output argument and on exit returns the triangular factor U or L from the Cholesky factorization $A = U^T * U$ or $A = L * L^T$ of the equilibrated matrix A (see the description of A for the form of the equilibrated matrix).
$equed$	If $fact \neq 'F'$, then $equed$ is an output argument. It specifies the form of equilibration that was done (see the description of $equed$ in <i>Input Arguments</i> section).
sr	This array is an output argument if $fact \neq 'F'$. See the description of sr in <i>Input Arguments</i> section.
sc	This array is an output argument if $fact \neq 'F'$. See the description of sc in <i>Input Arguments</i> section.
b	On exit, if $equed = 'N'$, b is not modified; if $trans = 'N'$ and $equed = 'R'$ or $'B'$, b is overwritten by $diag(r) * b$; if $trans = 'T'$ or $'C'$ and $equed = 'C'$ or $'B'$, b is overwritten by $diag(c) * b$.
x	(local) If $info = 0$ the n-by-$nrhs$ solution matrix X to the original system of equations. Note that A and B are modified on exit if $equed \neq 'N'$, and the solution to the equilibrated system is $inv(diag(sc)) * X$ if $trans = 'N'$ and $equed = 'C'$ or $'B'$, or $inv(diag(sr)) * X$ if $trans = 'T'$ or $'C'$ and $equed = 'R'$ or $'B'$.
$rcond$	(global) An estimate of the reciprocal condition number of the matrix A after equilibration (if done). If $rcond$ is less than the machine precision (in particular, if $rcond=0$), the matrix is singular to working precision. This condition is indicated by a return code of $info > 0$.
$ferr$	Arrays of size at least $\max(LOC, n\_b)$. The estimated forward error bounds for each solution vector $X(j)$ (the j -th column of the solution matrix X). If $xtrue$ is the true solution, $ferr[j - 1]$ bounds the magnitude of the largest entry in $(X(j) - xtrue)$ divided by the magnitude of the largest entry in

$X(j)$. The quality of the error bound depends on the quality of the estimate of $\text{norm}(\text{inv}(A))$ computed in the code; if the estimate of $\text{norm}(\text{inv}(A))$ is accurate, the error bound is guaranteed.

berr

(local)

Arrays of size at least $\max(LOC, n\_b)$. The componentwise relative backward error of each solution vector $X(j)$ (the smallest relative change in any entry of A or B that makes $X(j)$ an exact solution).

work[0]

(local) On exit, *work[0]* returns the minimal and optimal *liwork*.

info

(global)

If *info*=0, the execution is successful.

< 0: if *info* = -*i*, the *i*-th argument had an illegal value

> 0: if *info* = *i*, and *i* is $\leq n$: if *info* = *i*, the leading minor of order *i* of *a* is not positive definite, so the factorization could not be completed, and the solution and error bounds could not be computed.

= *n*+1: *rcond* is less than machine precision. The factorization has been completed, but the matrix is singular to working precision, and the solution and error bounds have not been computed.

Description

The p?pbsv function solves a system of linear equations

$$A(1:n, ja:ja+n-1) * X = B(ib:ib+n-1, 1:nrhs),$$

where $A(1:n, ja:ja+n-1)$ is an n -by- n real/complex banded symmetric positive definite distributed matrix with bandwidth bw .

Cholesky factorization is used to factor a reordering of the matrix into $L*L'$.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

<i>uplo</i>	(global) Must be 'U' or 'L'. Indicates whether the upper or lower triangular of A is stored. If <i>uplo</i> = 'U', the upper triangular A is stored If <i>uplo</i> = 'L', the lower triangular of A is stored.
<i>n</i>	(global) The order of the distributed matrix A ($n \geq 0$).
<i>bw</i>	(global) The number of subdiagonals in L or U . $0 \leq bw \leq n-1$.
<i>nrhs</i>	(global) The number of right-hand sides; the number of columns in B ($nrhs \geq 0$).
<i>a</i>	(local). Pointer into the local memory to an array with leading size $lld\_a \geq (bw+1)$ (stored in <i>desca</i>). On entry, this array contains the local pieces of the distributed matrix $sub(A)$ to be factored.
<i>ja</i>	(global) The index in the global matrix A indicating the start of the matrix to be operated on (which may be either all of A or a submatrix of A).
<i>desca</i>	(global and local) array of size <i>dlen</i> . The array descriptor for the distributed matrix A .
<i>b</i>	(local) Pointer into the local memory to an array of local lead size $lld\_b \geq nb$. On entry, this array contains the local pieces of the right hand sides $B(ib:ib+n-1, 1:nrhs)$.
<i>ib</i>	(global) The row index in the global matrix B indicating the first row of the matrix to be operated on (which may be either all of b or a submatrix of B).
<i>descb</i>	(global and local) array of size <i>dlen</i> . If 1D type (<i>dtype_b</i> = 502), <i>dlen</i> ≥ 7 ; If 2D type (<i>dtype_b</i> = 1), <i>dlen</i> ≥ 9 .

The array descriptor for the distributed matrix B .
Contains information of mapping of B to memory.

work (local).

Temporary workspace. This space may be overwritten in between calls to functions. *work* must be the size given in *lwork*.

lwork (local or global) Size of user-input workspace *work*. If *lwork* is too small, the minimal acceptable size will be returned in *work*[0] and an error code is returned. $lwork \geq (nb+2*bw)*bw + \max((bw*nrhs), bw*bw)$

Output Parameters

a On exit, this array contains information containing details of the factorization. Note that permutations are performed on the matrix, so that the factors returned are different from those returned by LAPACK.

b On exit, contains the local piece of the solutions distributed matrix X .

work On exit, *work*[0] contains the minimal *lwork*.

info (global) If *info*=0, the execution is successful.
< 0: If the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = $-(i*100+j)$, if the *i*-th argument is a scalar and had an illegal value, then *info* = $-i$.
> 0: If *info* = $k \leq \text{NPROCS}$, the submatrix stored on processor *info* and factored locally was not positive definite, and the factorization was not completed.
If *info* = $k > \text{NPROCS}$, the submatrix stored on processor *info*-NPROCS representing interactions with other processors was not positive definite, and the factorization was not completed.

Notice revision #20110804

Input Parameters

n	(global) The order of matrix A ($n \geq 0$).
$nrhs$	(global) The number of right-hand sides; the number of columns of the distributed submatrix B ($nrhs \geq 0$).
d	(local) Pointer to local part of global vector storing the main diagonal of the matrix.
e	(local) Pointer to local part of global vector storing the upper diagonal of the matrix. Globally, $du(n)$ is not referenced, and du must be aligned with d .
ja	(global) The index in the global matrix A indicating the start of the matrix to be operated on (which may be either all of A or a submatrix of A).
$desca$	(global and local) array of size $dlen$. If 1d type ($dtype\_a=501$ or 502), $dlen \geq 7$; If 2d type ($dtype\_a=1$), $dlen \geq 9$. The array descriptor for the distributed matrix A . Contains information of mapping of A to memory.
b	(local) Pointer into the local memory to an array of local lead size $lld\_b \geq nb$.

	On entry, this array contains the local pieces of the right hand sides $B(ib:ib+n-1, 1:nrhs)$.
<i>ib</i>	(global) The row index in the global matrix B indicating the first row of the matrix to be operated on (which may be either all of b or a submatrix of B).
<i>descb</i>	(global and local) array of size <i>dlen</i> . If 1d type (<i>dtype_b</i> = 502), <i>dlen</i> ≥ 7; If 2d type (<i>dtype_b</i> = 1), <i>dlen</i> ≥ 9. The array descriptor for the distributed matrix B . Contains information of mapping of B to memory.
<i>work</i>	(local). Temporary workspace. This space may be overwritten in between calls to functions. <i>work</i> must be the size given in <i>lwork</i> .
<i>lwork</i>	(local or global) Size of user-input workspace <i>work</i> . If <i>lwork</i> is too small, the minimal acceptable size will be returned in <i>work</i> [0] and an error code is returned. $lwork > (12*NPCOL+3*nb)+\max((10+2*\min(100, nrhs))*NPCOL+4*nrhs, 8*NPCOL)$.

Output Parameters

<i>d</i>	On exit, this array contains information containing the factors of the matrix. Must be of size greater than or equal to <i>desca</i> [<i>nb</i> - 1].
<i>e</i>	On exit, this array contains information containing the factors of the matrix. Must be of size greater than or equal to <i>desca</i> [<i>nb</i> - 1].
<i>b</i>	On exit, this contains the local piece of the solutions distributed matrix X .
<i>work</i>	On exit, <i>work</i> [0] contains the minimal <i>lwork</i> .
<i>info</i>	(local) If <i>info</i> =0, the execution is successful. < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = -(<i>i</i> *100+ <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> . > 0: If <i>info</i> = <i>k</i> ≤ NPROCS, the submatrix stored on processor <i>info</i> and factored locally was not positive definite, and the factorization was not completed. If <i>info</i> = <i>k</i> > NPROCS, the submatrix stored on processor <i>info</i> -NPROCS representing interactions with other processors was not positive definite, and the factorization was not completed.

```

Include Files

- mkl_scalapack.h

Description

The `p?gels` function solves overdetermined or underdetermined real/ complex linear systems involving an m -by- n matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$, or its transpose/ conjugate-transpose, using a QTQ or LQ factorization of $\text{sub}(A)$. It is assumed that $\text{sub}(A)$ has full rank.

The following options are provided:

1. If $\text{trans} = 'N'$ and $m \geq n$: find the least squares solution of an overdetermined system, that is, solve the least squares problem
2. If $\text{trans} = 'N'$ and $m < n$: find the minimum norm solution of an underdetermined system $\text{sub}(A) * X = \text{sub}(B)$.
3. If $\text{trans} = 'T'$ and $m \geq n$: find the minimum norm solution of an undetermined system $\text{sub}(A)^T * X = \text{sub}(B)$.
4. If $\text{trans} = 'T'$ and $m < n$: find the least squares solution of an overdetermined system, that is, solve the least squares problem

minimize $||\text{sub}(B) - \text{sub}(A) * X||$

minimize $||\text{sub}(B) - \text{sub}(A)^T * X||$,

where $\text{sub}(B)$ denotes $B(ib:ib+m-1, jb:jb+nrhs-1)$ when $\text{trans} = 'N'$ and $B(ib:ib+n-1, jb:jb+nrhs-1)$ otherwise. Several right hand side vectors b and solution vectors x can be handled in a single call; when $\text{trans} = 'N'$, the solution vectors are stored as the columns of the n -by- $nrhs$ right hand side matrix $\text{sub}(B)$ and the m -by- $nrhs$ right hand side matrix $\text{sub}(B)$ otherwise.

Input Parameters

<i>trans</i>	(global) Must be 'N', or 'T'. If $\text{trans} = 'N'$, the linear system involves matrix $\text{sub}(A)$; If $\text{trans} = 'T'$, the linear system involves the transposed matrix A^T (for real flavors only).
<i>m</i>	(global) The number of rows in the distributed matrix $\text{sub}(A)$ ($m \geq 0$).
<i>n</i>	(global) The number of columns in the distributed matrix $\text{sub}(A)$ ($n \geq 0$).

<i>nrhs</i>	(global) The number of right-hand sides; the number of columns in the distributed submatrices $\text{sub}(B)$ and X . ($nrhs \geq 0$).
<i>a</i>	(local) Pointer into the local memory to an array of size $lld\_a * LOCC(ja+n-1)$. On entry, contains the m -by- n matrix A .
<i>ia, ja</i>	(global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively.
<i>desca</i>	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix A .
<i>b</i>	(local) Pointer into the local memory to an array of local size $lld\_b * LOCC(jb + nrhs - 1)$. On entry, this array contains the local pieces of the distributed matrix B of right-hand side vectors, stored columnwise; $\text{sub}(B)$ is m -by- $nrhs$ if $trans = 'N'$, and n -by- $nrhs$ otherwise.
<i>ib, jb</i>	(global) The row and column indices in the global matrix B indicating the first row and the first column of the submatrix B , respectively.
<i>descb</i>	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix B .
<i>work</i>	(local) Workspace array with size $lwork$.
<i>lwork</i>	(local or global) . The size of the array <i>work/lwork</i> is local input and must be at least $lwork \geq ltau + \max(lwf, lws)$, where if $m > n$, then <pre> ltau = numroc(ja+min(m,n)-1, nb_a, MYCOL, csrc_a, NPCOL), lwf = nb_a*(mpa0 + nqa0 + nb_a) lws = max((nb_a*(nb_a-1))/2, (nrhsqb0 + mpb0)*nb_a) + nb_a*nb_a else ltau = numroc(ia+min(m,n)-1, mb_a, MYROW, rsrc_a, NPROW), lwf = mb_a * (mpa0 + nqa0 + mb_a) lws = max((mb_a*(mb_a-1))/2, (npb0 + max(nqa0 + numroc(numroc(n+iroffb, mb_a, 0, 0, NPROW), mb_a, 0, 0, lcmp), nrhsqb0))*mb_a) + mb_a*mb_a end if, where lcmp = lcm/NPROW with lcm = ilcm(NPROW, NPCOL), iroffa = mod(ia-1, mb_a), icoffa = mod(ja-1, nb_a), iarow = indxcg2p(ia, mb_a, MYROW, rsrc_a, NPROW), iacol= indxcg2p(ja, nb_a, MYROW, rsrc_a, NPROW) </pre>

```
mpa0 = numroc(m+iroffa, mb_a, MYROW, iarow, NPROW),
nqa0 = numroc(n+icoffa, nb_a, MYCOL, iacol, NPCOL),
iroffb = mod(ib-1, mb_b),
icoffb = mod(jb-1, nb_b),
ibrow = indxcg2p(ib, mb_b, MYROW, rsrc_b, NPROW),
ibcol = indxcg2p(jb, nb_b, MYCOL, csrc_b, NPCOL),
mpb0 = numroc(m+iroffb, mb_b, MYROW, icrow, NPROW),
nqb0 = numroc(n+icoffb, nb_b, MYCOL, ibcol, NPCOL),
```

NOTE

`mod(x,y)` is the integer remainder of x/y .

`ilcm`, `indxcg2p` and `numroc` are ScaLAPACK tool functions; `MYROW`, `MYCOL`, `NPROW`, and `NPCOL` can be determined by calling the function `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

<code>a</code>	On exit, If $m \geq n$, <code>sub(A)</code> is overwritten by the details of its <i>QR</i> factorization as returned by <code>p?geqrf</code> ; if $m < n$, <code>sub(A)</code> is overwritten by details of its <i>LQ</i> factorization as returned by <code>p?gelqf</code> .
<code>b</code>	On exit, <code>sub(B)</code> is overwritten by the solution vectors, stored columnwise: if <code>trans = 'N'</code> and $m \geq n$, rows 1 to n of <code>sub(B)</code> contain the least squares solution vectors; the residual sum of squares for the solution in each column is given by the sum of squares of elements $n+1$ to m in that column; If <code>trans = 'N'</code> and $m < n$, rows 1 to n of <code>sub(B)</code> contain the minimum norm solution vectors; If <code>trans = 'T'</code> and $m \geq n$, rows 1 to m of <code>sub(B)</code> contain the minimum norm solution vectors; if <code>trans = 'T'</code> and $m < n$, rows 1 to m of <code>sub(B)</code> contain the least squares solution vectors; the residual sum of squares for the solution in each column is given by the sum of squares of elements $m+1$ to n in that column.
<code>work[0]</code>	On exit, <code>work[0]</code> contains the minimum value of <code>lwork</code> required for optimum performance.
<code>info</code>	(global) = 0: the execution is successful. < 0: if the i -th argument is an array and the j -entry had an illegal value, then <code>info = - (i* 100+j)</code> , if the i -th argument is a scalar and had an illegal value, then <code>info = -i</code> .

p?syev

Computes selected eigenvalues and eigenvectors of a symmetric matrix.

Syntax

```
void pssyev (char *jobz , char *uplo , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , float *w , float *z , MKL_INT *iz , MKL_INT *jz , MKL_INT
*descz , float *work , MKL_INT *lwork , MKL_INT *info );

void pdsyev (char *jobz , char *uplo , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , double *w , double *z , MKL_INT *iz , MKL_INT *jz , MKL_INT
*descz , double *work , MKL_INT *lwork , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The `p?syev` function computes all eigenvalues and, optionally, eigenvectors of a real symmetric matrix A by calling the recommended sequence of ScaLAPACK functions.

In its present form, the function assumes a homogeneous system and makes no checks for consistency of the eigenvalues or eigenvectors across the different processes. Because of this, it is possible that a heterogeneous system may return incorrect results without any error messages.

Input Parameters

np = the number of rows local to a given process.

nq = the number of columns local to a given process.

<i>jobz</i>	(global) Must be 'N' or 'V'. Specifies if it is necessary to compute the eigenvectors: If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>uplo</i>	(global) Must be 'U' or 'L'. Specifies whether the upper or lower triangular part of the symmetric matrix A is stored: If <i>uplo</i> = 'U', a stores the upper triangular part of A . If <i>uplo</i> = 'L', a stores the lower triangular part of A .
<i>n</i>	(global) The number of rows and columns of the matrix A ($n \geq 0$).
<i>a</i>	(local) Block cyclic array of global size $n*n$ and local size $lld\_a*LOCc(ja+n-1)$. On entry, the symmetric matrix A . If <i>uplo</i> = 'U', only the upper triangular part of A is used to define the elements of the symmetric matrix. If <i>uplo</i> = 'L', only the lower triangular part of A is used to define the elements of the symmetric matrix.

<i>ia, ja</i>	(global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .
<i>iz, jz</i>	(global) The row and column indices in the global matrix <i>Z</i> indicating the first row and the first column of the submatrix <i>Z</i> , respectively.
<i>descz</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>Z</i> .
<i>work</i>	(local) Array of size <i>lwork</i> .
<i>lwork</i>	(local) See below for definitions of variables used to define <i>lwork</i>. If no eigenvectors are requested (<i>jobz</i> = 'N'), then $lwork \geq 5*n + sizesytrd + 1$, where <i>sizesytrd</i> is the workspace for <i>p?sytrd</i> and is $\max(NB*(np + 1), 3*NB)$. If eigenvectors are requested (<i>jobz</i> = 'V') then the amount of workspace required to guarantee that all eigenvectors are computed is: $qrmem = 2*n - 2$ $lwmin = 5*n + n*ldc + \max(sizemqrleft, qrmem) + 1$ Variable definitions: $nb = desca[mb\_ - 1] = desca[nb\_ - 1] = descz[mb\_ - 1] = descz[nb\_ - 1];$ $nn = \max(n, nb, 2);$ $desca[rsrc\_ - 1] = desca[rsrc\_ - 1] = descz[rsrc\_ - 1] = descz[csrc\_ - 1] = 0$ $np = \text{numroc}(nn, nb, 0, 0, \text{NPROW})$ $nq = \text{numroc}(\max(n, nb, 2), nb, 0, 0, \text{NPCOL})$ $nrc = \text{numroc}(n, nb, \text{myprowc}, 0, \text{NPROCS})$ $ldc = \max(1, nrc)$ <i>sizemqrleft</i> is the workspace for <i>p?ormtr</i> when its <i>side</i> argument is 'L'. <i>myprowc</i> is defined when a new context is created as follows: <pre>call blacs_get(desca[ctxt_ - 1], 0, contextc) call blacs_gridinit(contextc, 'R', NPROCS, 1) call blacs_gridinfo(contextc, nprowc, npcold, myprowc, mypcold)</pre> If <i>lwork</i> = -1, then <i>lwork</i> is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by <i>p?erbla</i>.

Output Parameters

<i>a</i>	On exit, the lower triangle (if <i>uplo</i> ='L') or the upper triangle (if <i>uplo</i> ='U') of <i>A</i> , including the diagonal, is destroyed.
<i>w</i>	(global). Array of size <i>n</i> . On normal exit, the first <i>m</i> entries contain the selected eigenvalues in ascending order.
<i>z</i>	(local). Array, global size $n*n$, local size $lld\_z*LOCc(jz+n-1)$. If <i>jobz</i> = 'V', then on normal exit the first <i>m</i> columns of <i>z</i> contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues. If <i>jobz</i> = 'N', then <i>z</i> is not referenced.
<i>work</i> [0]	On output, <i>work</i> [0] returns the workspace needed to guarantee completion. If the input parameters are incorrect, <i>work</i> [0] may also be incorrect. If <i>jobz</i> = 'N' <i>work</i> [0] = minimal (optimal) amount of workspace If <i>jobz</i> = 'V' <i>work</i> [0] = minimal workspace required to generate all the eigenvectors.
<i>info</i>	(global) If <i>info</i> = 0, the execution is successful. If <i>info</i> < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = $-(i*100+j)$, if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = $-i$. If <i>info</i> > 0: If <i>info</i> = 1 through <i>n</i> , the <i>i</i> -th eigenvalue did not converge in <i>steqr2</i> after a total of $30n$ iterations. If <i>info</i> = <i>n</i> +1, then <i>p?syev</i> has detected heterogeneity by finding that eigenvalues were not identical across the process grid. In this case, the accuracy of the results from <i>p?syev</i> cannot be guaranteed.

Description

The `p?syevd` function computes all eigenvalues and eigenvectors of a real symmetric matrix A by using a divide and conquer algorithm.

Input Parameters

np = the number of rows local to a given process.

nq = the number of columns local to a given process.

<i>jobz</i>	(global) Must be 'N' or 'V'. Specifies if it is necessary to compute the eigenvectors: If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>uplo</i>	(global) Must be 'U' or 'L'. Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored: If <i>uplo</i> = 'U', a stores the upper triangular part of A . If <i>uplo</i> = 'L', a stores the lower triangular part of A .
<i>n</i>	(global) The number of rows and columns of the matrix A ($n \geq 0$).
<i>a</i>	(local). Block cyclic array of global size $n*n$ and local size $lld\_a*LOCc(ja+n-1)$. On entry, the symmetric matrix A . If <i>uplo</i> = 'U', only the upper triangular part of A is used to define the elements of the symmetric matrix. If <i>uplo</i> = 'L', only the lower triangular part of A is used to define the elements of the symmetric matrix.
<i>ia, ja</i>	(global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively.
<i>desca</i>	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix A . If <i>desca</i> [<i>ctxt_</i> - 1] is incorrect, <code>p?syevd</code> cannot guarantee correct error reporting.
<i>iz, jz</i>	(global) The row and column indices in the global matrix Z indicating the first row and the first column of the submatrix Z , respectively.
<i>descz</i>	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix Z . <i>descz</i> [<i>ctxt_</i> - 1] must equal <i>desca</i> [<i>ctxt_</i> - 1].

<i>work</i>	(local). Array of size <i>lwork</i> .
<i>lwork</i>	(local) The size of the array <i>work</i> . If eigenvalues are requested: $lwork \geq \max(1 + 6*n + 2*np*nq, \text{trilwmin}) + 2*n$ with $\text{trilwmin} = 3*n + \max(nb*(np + 1), 3*nb)$ $np = \text{numroc}(n, nb, \text{myrow}, \text{iarrow}, \text{NPROW})$ $nq = \text{numroc}(n, nb, \text{mycol}, \text{iacol}, \text{NPCOL})$ If <i>lwork</i> = -1, then <i>lwork</i> is global input and a workspace query is assumed; the function only calculates the size required for optimal performance for all work arrays. The required workspace is returned as the first element of the corresponding work arrays, and no error message is issued by p_xerbla.
<i>iwork</i>	(local) Workspace array of size <i>liwork</i> .
<i>liwork</i>	(local) , size of <i>iwork</i> . $liwork = 7*n + 8*npcol + 2.$

Output Parameters

<i>a</i>	On exit, the lower triangle (if <i>uplo</i> = 'L'), or the upper triangle (if <i>uplo</i> = 'U') of <i>A</i> , including the diagonal, is overwritten.
<i>w</i>	(global). Array of size <i>n</i> . If <i>info</i> = 0, <i>w</i> contains the eigenvalues in the ascending order.
<i>z</i>	(local). Array, global size (<i>n</i> , <i>n</i>), local size $\text{lld\_z} * \text{LOCc}(jz+n-1)$. The <i>z</i> parameter contains the orthonormal eigenvectors of the matrix <i>A</i> .
<i>work</i> [0]	On exit, returns adequate workspace to allow optimal performance.
<i>iwork</i> [0]	(local). On exit, if <i>liwork</i> > 0, <i>iwork</i> [0] returns the optimal <i>liwork</i> .
<i>info</i>	(global) If <i>info</i> = 0, the execution is successful. If <i>info</i> < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then $info = -(i*100+j)$. If the <i>i</i> -th argument is a scalar and had an illegal value, then $info = -i$. If <i>info</i> > 0:

The algorithm failed to compute the $info/(n+1)$ -th eigenvalue while working on the submatrix lying in global rows and columns $\text{mod}(info, n+1)$.

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

Description

`p?syevr` computes selected eigenvalues and, optionally, eigenvectors of a real symmetric matrix A distributed in 2D blockcyclic format by calling the recommended sequence of ScaLAPACK functions.

First, the matrix A is reduced to real symmetric tridiagonal form. Then, the eigenproblem is solved using the parallel MRRR algorithm. Last, if eigenvectors have been computed, a backtransformation is done.

Upon successful completion, each processor stores a copy of all computed eigenvalues in w . The eigenvector matrix z is stored in 2D block-cyclic format distributed over all processors.

Note that subsets of eigenvalues/vectors can be selected by specifying a range of values or a range of indices for the desired eigenvalues.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Optimization Notice

Notice revision #20110804

Input Parameters

<i>jobz</i>	(global) Specifies whether or not to compute the eigenvectors: = 'N': Compute eigenvalues only. = 'V': Compute eigenvalues and eigenvectors.
<i>range</i>	(global) = 'A': all eigenvalues will be found. = 'V': all eigenvalues in the interval $[vl, vu]$ will be found. = 'I': the <i>il</i> -th through <i>iu</i> -th eigenvalues will be found.
<i>uplo</i>	(global) Specifies whether the upper or lower triangular part of the symmetric matrix <i>A</i> is stored: = 'U': Upper triangular = 'L': Lower triangular
<i>n</i>	(global) The number of rows and columns of the matrix <i>a</i> . $n \geq 0$
<i>a</i>	Block cyclic array of global size $n * n$, local size $lld\_a * LOC_c(ja+n-1)$. This array contains the local pieces of the symmetric distributed matrix <i>A</i> . If <i>uplo</i> = 'U', only the upper triangular part of <i>a</i> is used to define the elements of the symmetric matrix. If <i>uplo</i> = 'L', only the lower triangular part of <i>a</i> is used to define the elements of the symmetric matrix. On exit, the lower triangle (if <i>uplo</i> ='L') or the upper triangle (if <i>uplo</i> ='U') of <i>a</i> , including the diagonal, is destroyed.
<i>ia</i>	(global) Global row index in the global matrix <i>A</i> that points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix.
<i>ja</i>	(global) Global column index in the global matrix <i>A</i> that points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix.
<i>desca</i>	(global and local) array of size $dlen\_ = 9$. The array descriptor for the distributed matrix <i>a</i> .
<i>vl</i>	(global)

If *range*='V', the lower bound of the interval to be searched for eigenvalues. Not referenced if *range* = 'A' or 'I'.

vu

(global)

If *range*='V', the upper bound of the interval to be searched for eigenvalues. Not referenced if *range* = 'A' or 'I'.

il

(global)

If *range*='I', the index (from smallest to largest) of the smallest eigenvalue to be returned. $il \geq 1$.

Not referenced if *range* = 'A'.

iu

(global)

If *range*='I', the index (from smallest to largest) of the largest eigenvalue to be returned. $\min(il, n) \leq iu \leq n$.

Not referenced if *range* = 'A'.

iz

(global)

Global row index in the global matrix *Z* that points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix.

jz

(global)

Global column index in the global matrix *Z* that points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix.

descz

array of size *dlen_*.

The array descriptor for the distributed matrix *z*.

The context *descz*[*ctxt_* - 1] must equal *desca*[*ctxt_* - 1]. Also note the array alignment requirements specified below.

work

(local workspace) array of size *lwork*

lwork

(local)

Size of *work*, must be at least 3.

See below for definitions of variables used to define *lwork*.

If no eigenvectors are requested (*jobz* = 'N') then

$$lwork \geq 2 + 5*n + \max(12 * nn, neig * (np0 + 1))$$

If eigenvectors are requested (*jobz* = 'V') then the amount of workspace required is:

$$lwork \geq 2 + 5*n + \max(18*nn, np0 * mq0 + 2 * neig * neig) + (2 + \text{iceil}(neig, nprow*npcol))*nn$$

Variable definitions:

neig = number of eigenvectors requested

$$nb = \text{desca}[mb\_ - 1] = \text{desca}(nb\_) = \text{descz}[mb\_ - 1] = \text{descz}(nb\_)$$

$nn = \max(n, neig, 2)$

$desca[rsrc\_ - 1] = desca[csrc\_nb\_ - 1] = deszcz[rsrc\_ - 1] =$
 $deszcz[csrc\_ - 1] = 0$

$np0 = \text{numroc}(nn, neig, 0, 0, nprow)$

$mq0 = \text{numroc}(\max(neig, neig, 2), neig, 0, 0, npcol)$

$\text{iceil}(x, y)$ is a ScaLAPACK function returning $\text{ceiling}(x/y)$, and $nprow$ and $npcol$ can be determined by calling the function `blacs_gridinfo`.

If $liwork = -1$, then $liwork$ is global input and a workspace query is assumed; the function only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by `pxerbla`.

$liwork$

(local)

size of $iwork$

Let $nnp = \max(n, nprow*npcol + 1, 4)$. Then:

$liwork \geq 12*nnp + 2*n$ when the eigenvectors are desired

$liwork \geq 10*nnp + 2*n$ when only the eigenvalues have to be computed

If $liwork = -1$, then $liwork$ is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

OUTPUT Parameters

m

(global)

Total number of eigenvalues found. $0 \leq m \leq n$.

nz

(global)

Total number of eigenvectors computed. $0 \leq nz \leq m$.

The number of columns of z that are filled.

If $jobz \neq 'V'$, nz is not referenced.

If $jobz = 'V'$, $nz = m$

w

(global) array of size n

Upon successful exit, the first m entries contain the selected eigenvalues in ascending order.

z

Block-cyclic array, global size $n*n$, local size $lld\_z*LOC_c(jz+n-1)$.

On exit, contains local pieces of distributed matrix Z .

$work$

On return, $work[0]$ contains the optimal amount of workspace required for efficient execution. If $jobz='N'$ $work[0]$ = optimal amount of workspace required to compute the eigenvalues. If $jobz='V'$ $work[0]$ = optimal amount of workspace required to compute eigenvalues and eigenvectors.

<i>iwork</i>	(local workspace) array On return, <i>iwork</i> [0] contains the amount of integer workspace required.
<i>info</i>	(global) = 0: successful exit < 0: If the <i>i</i> -th argument is an array and the <i>j</i> th-entry had an illegal value, then <i>info</i> = -(<i>i</i> *100+ <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

Application Notes

The distributed submatrices $a(ia:*, ja:*)$ and $z(iz:iz+m-1, jz:jz+n-1)$ must satisfy the following alignment properties:

1. Identical (quadratic) dimension: $desca[m_ - 1] = descz[m_ - 1] = desca[n_ - 1] = descz[n_ - 1]$
2. Quadratic conformal blocking: $desca[mb_ - 1] = desca[nb_ - 1] = descz[mb_ - 1] = descz[nb_ - 1]$,
 $desca[rsrc_ - 1] = descz[rsrc_ - 1]$
3. $\text{mod}(ia-1, mb_a) = \text{mod}(iz-1, mb_z) = 0$

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

Notice revision #20110804

Input Parameters

np = the number of rows local to a given process.

nq = the number of columns local to a given process.

<i>jobz</i>	(global) Must be 'N' or 'V'. Specifies if it is necessary to compute the eigenvectors: If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>range</i>	(global) Must be 'A', 'V', or 'I'. If <i>range</i> = 'A', all eigenvalues will be found. If <i>range</i> = 'V', all eigenvalues in the half-open interval [<i>vl</i> , <i>vu</i>] will be found. If <i>range</i> = 'I', the eigenvalues with indices <i>il</i> through <i>iu</i> will be found.
<i>uplo</i>	(global) Must be 'U' or 'L'. Specifies whether the upper or lower triangular part of the symmetric matrix <i>A</i> is stored: If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular part of <i>A</i> . If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular part of <i>A</i> .
<i>n</i>	(global) The number of rows and columns of the matrix <i>A</i> ($n \geq 0$).
<i>a</i>	(local). Block cyclic array of global size $n*n$ and local size $lld\_a*LOCc(ja+n-1)$. On entry, the symmetric matrix <i>A</i> . If <i>uplo</i> = 'U', only the upper triangular part of <i>A</i> is used to define the elements of the symmetric matrix. If <i>uplo</i> = 'L', only the lower triangular part of <i>A</i> is used to define the elements of the symmetric matrix.
<i>ia, ja</i>	(global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .

<i>vl, vu</i>	(global) If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues; $vl \leq vu$. Not referenced if <i>range</i> = 'A' or 'I'.
<i>il, iu</i>	(global) If <i>range</i> = 'I', the indices of the smallest and largest eigenvalues to be returned. Constraints: $il \geq 1$ $\min(il, n) \leq iu \leq n$ Not referenced if <i>range</i> = 'A' or 'V'.
<i>abstol</i>	(global). If <i>jobz</i>='V', setting <i>abstol</i> to <code>p?lamch(context, 'U')</code> yields the most orthogonal eigenvectors. The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a, b]$ of width less than or equal to $abstol + eps * \max(a , b),$ where <i>eps</i> is the machine precision. If <i>abstol</i> is less than or equal to zero, then $eps * \text{norm}(T)$ will be used in its place, where $\text{norm}(T)$ is the 1-norm of the tridiagonal matrix obtained by reducing <i>A</i> to tridiagonal form. Eigenvalues will be computed most accurately when <i>abstol</i> is set to twice the underflow threshold $2 * p?lamch('S')$ not zero. If this function returns with $(\text{mod}(\text{info}, 2) \neq 0)$ or $(\text{mod}(\text{info}/8, 2) \neq 0)$, indicating that some eigenvalues or eigenvectors did not converge, try setting <i>abstol</i> to $2 * p?lamch('S')$.
<i>orfac</i>	(global). Specifies which eigenvectors should be reorthogonalized. Eigenvectors that correspond to eigenvalues which are within $tol = orfac * \text{norm}(A)$ of each other are to be reorthogonalized. However, if the workspace is insufficient (see <i>lwork</i>), <i>tol</i> may be decreased until all eigenvectors to be reorthogonalized can be stored in one process. No reorthogonalization will be done if <i>orfac</i> equals zero. A default value of 1.0e-3 is used if <i>orfac</i> is negative. <i>orfac</i> should be identical on all processes.
<i>iz, jz</i>	(global) The row and column indices in the global matrix <i>Z</i> indicating the first row and the first column of the submatrix <i>Z</i>, respectively.
<i>descz</i>	(global and local) array of size <i>dlen_</i>. The array descriptor for the distributed matrix <i>Z</i>. <i>descz</i>[<i>ctxt_</i> - 1] must equal <i>desca</i>[<i>ctxt_</i> - 1].
<i>work</i>	(local) Array of size <i>lwork</i>.
<i>lwork</i>	(local) The size of the array <i>work</i>. See below for definitions of variables used to define <i>lwork</i>. If no eigenvectors are requested (<i>jobz</i> = 'N'), then $lwork \geq 5 * n + \max(5 * nn, NB * (np0 + 1))$.

If eigenvectors are requested (*jobz* = 'V'), then the amount of workspace required to guarantee that all eigenvectors are computed is:

$$lwork \geq 5*n + \max(5*nn, np0*mq0 + 2*NB*NB) + \text{iceil}(neig, \text{NPROW}*NPCOL)*nn$$

The computed eigenvectors may not be orthogonal if the minimal workspace is supplied and *orfac* is too small. If you want to guarantee orthogonality (at the cost of potentially poor performance) you should add the following to *lwork*:

$$(clustersize-1)*n,$$

where *clustersize* is the number of eigenvalues in the largest cluster, where a cluster is defined as a set of close eigenvalues:

$$\{w[k-1], \dots, w[k+clustersize-2] | w[j] \leq w[j-1]\} + orfac*2*norm(A),$$

where

neig = number of eigenvectors requested

$$nb = desca[mb\_ - 1] = desca[nb\_ - 1] = descz[mb\_ - 1] = descz[nb\_ - 1];$$

$$nn = \max(n, nb, 2);$$

$$desca[rsrc\_ - 1] = desca[nb\_ - 1] = descz[rsrc\_ - 1] = descz[csrc\_ - 1] = 0;$$

$$np0 = \text{numroc}(nn, nb, 0, 0, \text{NPROW});$$

$$mq0 = \text{numroc}(\max(neig, nb, 2), nb, 0, 0, \text{NPCOL})$$

iceil(*x*, *y*) is a ScaLAPACK function returning ceiling(*x*/*y*)

If *lwork* is too small to guarantee orthogonality, *p?syevx* attempts to maintain orthogonality in the clusters with the smallest spacing between the eigenvalues.

If *lwork* is too small to compute all the eigenvectors requested, no computation is performed and *info*= -23 is returned.

Note that when *range*='V', number of requested eigenvectors are not known until the eigenvalues are computed. In this case and if *lwork* is large enough to compute the eigenvalues, *p?sygvx* computes the eigenvalues and as many eigenvectors as possible.

Relationship between workspace, orthogonality & performance:

Greater performance can be achieved if adequate workspace is provided. In some situations, performance can decrease as the provided workspace increases above the workspace amount shown below:

$$lwork \geq \max(lwork, 5*n + nsytrd\_lwopt),$$

where *lwork*, as defined previously, depends upon the number of eigenvectors requested, and

$$nsytrd\_lwopt = n + 2*(anb+1)*(4*nps+2) + (nps + 3)*nps;$$

$$anb = \text{pjlaenv}(desca[ctxt\_ - 1], 3, 'p?sytrd', 'L', 0, 0, 0, 0);$$

$$sqnpc = \text{int}(\text{sqrt}(\text{dble}(\text{NPROW} * \text{NPCOL})));$$

$nps = \max(\text{numroc}(n, 1, 0, 0, sqnpc), 2*anb);$

`numroc` is a ScaLAPACK tool functions;

`pjlaenv` is a ScaLAPACK environmental inquiry function

`MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the function `blacs_gridinfo`.

For large n , no extra workspace is needed, however the biggest boost in performance comes for small n , so it is wise to provide the extra workspace (typically less than a megabyte per process).

If $clustersize > n/\sqrt{NPROW*NPCOL}$, then providing enough space to compute all the eigenvectors orthogonally will cause serious degradation in performance. At the limit (that is, $clustersize = n-1$) `p?stein` will perform no better than `?stein` on single processor.

For $clustersize = n/\sqrt{NPROW*NPCOL}$ reorthogonalizing all eigenvectors will increase the total execution time by a factor of 2 or more.

For $clustersize > n/\sqrt{NPROW*NPCOL}$ execution time will grow as the square of the cluster size, all other factors remaining equal and assuming enough workspace. Less workspace means less reorthogonalization but faster execution.

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the function only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by `p?xerbla`.

$iwork$

(local) Workspace array.

$liwork$

(local) , size of $iwork$. $liwork \geq 6*nnp$

Where: $nnp = \max(n, NPROW*NPCOL + 1, 4)$

If $liwork = -1$, then $liwork$ is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `p?xerbla`.

Output Parameters

a

On exit, the lower triangle (if $uplo = 'L'$) or the upper triangle (if $uplo = 'U'$) of A , including the diagonal, is overwritten.

m

(global) The total number of eigenvalues found; $0 \leq m \leq n$.

nz

(global) Total number of eigenvectors computed. $0 \leq nz \leq m$.

The number of columns of z that are filled.

If $jobz \neq 'V'$, nz is not referenced.

If $jobz = 'V'$, $nz = m$ unless the user supplies insufficient space and `p?syevx` is not able to detect this before beginning computation. To get all the eigenvectors requested, the user must supply both sufficient space to hold

the eigenvectors in z ($m \leq \text{descz}[n\_ - 1]$) and sufficient workspace to compute them. (See *lwork*). `p?syevx` is always able to detect insufficient space without computation unless *range* = 'V'.

w

(global).

Array of size n . The first m elements contain the selected eigenvalues in ascending order.

z

(local).

Array, global size $n*n$, local size $\text{lld\_}z * \text{LOCc}(jz+n-1)$.

If *jobz* = 'V', then on normal exit the first m columns of z contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues. If an eigenvector fails to converge, then that column of z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in *ifail*.

If *jobz* = 'N', then z is not referenced.

work[0]

On exit, returns workspace adequate workspace to allow optimal performance.

iwork[0]

On return, *iwork[0]* contains the amount of integer workspace required.

ifail

(global).

Array of size n .

If *jobz* = 'V', then on normal exit, the first m elements of *ifail* are zero. If $(\text{mod}(\text{info}, 2) \neq 0)$ on exit, then *ifail* contains the indices of the eigenvectors that failed to converge.

If *jobz* = 'N', then *ifail* is not referenced.

iclustr(global) Array of size $(2 * \text{NPROW} * \text{NPCOL})$

This array contains indices of eigenvectors corresponding to a cluster of eigenvalues that could not be reorthogonalized due to insufficient workspace (see *lwork*, *orfac* and *info*). Eigenvectors corresponding to clusters of eigenvalues indexed *iclustr*(2*i-1) to *iclustr*(2*i), could not be reorthogonalized due to lack of workspace. Hence the eigenvectors corresponding to these clusters may not be orthogonal. *iclustr* is a zero terminated array. *iclustr*[2*k - 1] $\neq 0$ and *iclustr*[2*k] = 0 if and only if k is the number of clusters.

iclustr is not referenced if *jobz* = 'N'.

gap

(global)

Array of size $\text{NPROW} * \text{NPCOL}$

This array contains the gap between eigenvalues whose eigenvectors could not be reorthogonalized. The output values in this array correspond to the clusters indicated by the array *iclustr*. As a result, the dot product between eigenvectors corresponding to the i th cluster may be as high as $(C*n) / \text{gap}[i - 1]$ where C is a small constant.

info

(global)

If *info* = 0, the execution is successful.

If $info < 0$:

If the i -th argument is an array and the j -entry had an illegal value, then $info = -(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

If $info > 0$: if $(\text{mod}(info, 2) \neq 0)$, then one or more eigenvectors failed to converge. Their indices are stored in $ifail$. Ensure $abstol=2.0*p?lamch('U')$.

If $(\text{mod}(info/2, 2) \neq 0)$, then eigenvectors corresponding to one or more clusters of eigenvalues could not be reorthogonalized because of insufficient workspace. The indices of the clusters are stored in the array $iclustr$.

If $(\text{mod}(info/4, 2) \neq 0)$, then space limit prevented $p?syevxf$ from computing all of the eigenvectors between vl and vu . The number of eigenvectors computed is returned in nz .

If $(\text{mod}(info/8, 2) \neq 0)$, then $p?stebz$ failed to compute eigenvalues. Ensure $abstol=2.0*p?lamch('U')$.

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

*lrwork , MKL_INT *info );
```

Include Files

- `mkl_scalapack.h`

Description

The `p?heev` function computes all eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix A by calling the recommended sequence of ScaLAPACK functions. The function assumes a homogeneous system and makes spot checks of the consistency of the eigenvalues across the different processes. A heterogeneous system may return incorrect results without any error messages.

Input Parameters

np = the number of rows local to a given process.

nq = the number of columns local to a given process.

<i>jobz</i>	(global) Must be 'N' or 'V'. Specifies if it is necessary to compute the eigenvectors: If <i>jobz</i> = 'N', then only eigenvalues are computed. If <i>jobz</i> = 'V', then eigenvalues and eigenvectors are computed.
<i>uplo</i>	(global) Must be 'U' or 'L'. Specifies whether the upper or lower triangular part of the Hermitian matrix <i>A</i> is stored: If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular part of <i>A</i>. If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular part of <i>A</i>.
<i>n</i>	(global) The number of rows and columns of the matrix <i>A</i> ($n \geq 0$).
<i>a</i>	(local). Block cyclic array of global size $n*n$ and local size $lld\_a*LOCc(ja+n-1)$. On entry, the Hermitian matrix <i>A</i>. If <i>uplo</i> = 'U', only the upper triangular part of <i>A</i> is used to define the elements of the Hermitian matrix. If <i>uplo</i> = 'L', only the lower triangular part of <i>A</i> is used to define the elements of the Hermitian matrix.
<i>ia, ja</i>	(global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> . If <i>desca</i> [<i>ctxt_</i> - 1] is incorrect, p?heev cannot guarantee correct error reporting.
<i>iz, jz</i>	(global) The row and column indices in the global matrix <i>Z</i> indicating the first row and the first column of the submatrix <i>Z</i> , respectively.
<i>descz</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>Z</i> . <i>descz</i> [<i>ctxt_</i> - 1] must equal <i>desca</i> [<i>ctxt_</i> - 1].
<i>work</i>	(local). Array of size <i>lwork</i>.
<i>lwork</i>	(local) The size of the array <i>work</i>. If only eigenvalues are requested (<i>jobz</i> = 'N'): $lwork \geq \max(nb*(np0 + 1), 3) + 3*n$ If eigenvectors are requested (<i>jobz</i> = 'V'), then the amount of workspace required: $lwork \geq (np0+nq0+nb)*nb + 3*n + n^2$ with $nb = desca[mb\_ - 1] = desca[nb\_ - 1] = nb = descz[mb\_ - 1] = descz[nb\_ - 1]$ $np0 = \text{numroc}(nn, nb, 0, 0, \text{NPROW}).$ $nq0 = \text{numroc}(\max(n, nb, 2), nb, 0, 0, \text{NPCOL}).$

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the function only calculates the size required for optimal performance for all work arrays. The required workspace is returned as the first element of the corresponding work arrays, and no error message is issued by `pxerbla`.

$rwork$

(local).

Workspace array of size $lwork$.

$lrwork$

(local) The size of the array $rwork$.

See below for definitions of variables used to define $lrwork$.

If no eigenvectors are requested ($jobz = 'N'$), then $lrwork \geq 2*n$.

If eigenvectors are requested ($jobz = 'V'$), then $lrwork \geq 2*n + 2*n-2$.

If $lrwork = -1$, then $lrwork$ is global input and a workspace query is assumed; the function only calculates the minimum size required for the $rwork$ array. The required workspace is returned as the first element of $rwork$, and no error message is issued by `pxerbla`.

Output Parameters

a

On exit, the lower triangle (if $uplo = 'L'$), or the upper triangle (if $uplo = 'U'$) of A , including the diagonal, is overwritten.

w

(global).

Array of size n . The first m elements contain the selected eigenvalues in ascending order.

z

(local).

Array, global size $n*n$, local size $lld\_z*LOCc(jz+n-1)$.

If $jobz = 'V'$, then on normal exit the first m columns of z contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues. If an eigenvector fails to converge, then that column of z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in *ifail*.

If $jobz = 'N'$, then z is not referenced.

$work[0]$

On exit, returns adequate workspace to allow optimal performance.

If $jobz = 'N'$, then $work[0]$ = minimal workspace only for eigenvalues.

If $jobz = 'V'$, then $work[0]$ = minimal workspace required to generate all the eigenvectors.

$rwork[0]$

(local)

On output, $rwork[0]$ returns workspace required to guarantee completion.

$info$

(global)

If $info = 0$, the execution is successful.

If $info < 0$:

If the i -th argument is an array and the j -entry had an illegal value, then $info = -(i*100+j)$. If the i -th argument is a scalar and had an illegal value, then $info = -i$.

If $info > 0$:

If $info = 1$ through n , the i -th eigenvalue did not converge in [?steqr2](#) after a total of $30*n$ iterations.

If $info = n+1$, then [p?heevd](#) detected heterogeneity, and the accuracy of the results cannot be guaranteed.

See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

p?heevd

Computes all eigenvalues and eigenvectors of a complex Hermitian matrix by using a divide and conquer algorithm.

Syntax

```
void pcheevd (char *jobz , char *uplo , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , float *w , MKL_Complex8 *z , MKL_INT *iz , MKL_INT
*jz , MKL_INT *descz , MKL_Complex8 *work , MKL_INT *lwork , float *rwork , MKL_INT
*lrwork , MKL_INT *iwork , MKL_INT *liwork , MKL_INT *info );

void pzheevd (char *jobz , char *uplo , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , double *w , MKL_Complex16 *z , MKL_INT *iz , MKL_INT
*jz , MKL_INT *descz , MKL_Complex16 *work , MKL_INT *lwork , double *rwork , MKL_INT
*lrwork , MKL_INT *iwork , MKL_INT *liwork , MKL_INT *info );
```

Description

The [p?heevd](#) function computes all eigenvalues and eigenvectors of a complex Hermitian matrix A by using a divide and conquer algorithm.

Input Parameters

np = the number of rows local to a given process.

nq = the number of columns local to a given process.

jobz (global) Must be 'N' or 'V'.
Specifies if it is necessary to compute the eigenvectors:
If *jobz* = 'N', then only eigenvalues are computed.
If *jobz* = 'V', then eigenvalues and eigenvectors are computed.

uplo (global) Must be 'U' or 'L'.
Specifies whether the upper or lower triangular part of the Hermitian matrix A is stored:
If *uplo* = 'U', a stores the upper triangular part of A .

	If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular part of <i>A</i> .
<i>n</i>	(global) The number of rows and columns of the matrix <i>A</i> ($n \geq 0$).
<i>a</i>	(local). Block cyclic array of global size $n*n$ and local size $lld\_a*LOCc(ja+n-1)$. On entry, the Hermitian matrix <i>A</i> . If <i>uplo</i> = 'U', only the upper triangular part of <i>A</i> is used to define the elements of the Hermitian matrix. If <i>uplo</i> = 'L', only the lower triangular part of <i>A</i> is used to define the elements of the Hermitian matrix.
<i>ia, ja</i>	(global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> . If <i>desca</i> [<i>ctxt_</i> - 1] is incorrect, p?heevd cannot guarantee correct error reporting.
<i>iz, jz</i>	(global) The row and column indices in the global matrix <i>Z</i> indicating the first row and the first column of the submatrix <i>Z</i> , respectively.
<i>descz</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>Z</i> . <i>descz</i> [<i>ctxt_</i> - 1] must equal <i>desca</i> [<i>ctxt_</i> - 1].
<i>work</i>	(local). Array of size <i>lwork</i> .
<i>lwork</i>	(local) The size of the array <i>work</i> . If eigenvalues are requested: $lwork = n + (nb0 + mq0 + nb)*nb$ with $np0 = \text{numroc}(\max(n, nb, 2), nb, 0, 0, \text{NPROW})$ $mq0 = \text{numroc}(\max(n, nb, 2), nb, 0, 0, \text{NPCOL})$ If <i>lwork</i> = -1, then <i>lwork</i> is global input and a workspace query is assumed; the function only calculates the size required for optimal performance for all work arrays. The required workspace is returned as the first element of the corresponding work arrays, and no error message is issued by p?xerbla.
<i>rwork</i>	(local). Workspace array of size <i>lrwork</i> .
<i>lrwork</i>	(local) The size of the array <i>rwork</i> . $lrwork \geq 1 + 9*n + 3*np*nq,$ with $np = \text{numroc}(n, nb, myrow, iarow, \text{NPROW})$ $nq = \text{numroc}(n, nb, mycol, iacol, \text{NPCOL})$
<i>iwork</i>	(local) Workspace array of size <i>liwork</i> .
<i>liwork</i>	(local) , size of <i>iwork</i> .

$$liwork = 7*n + 8*npcol + 2.$$

Output Parameters

<i>a</i>	On exit, the lower triangle (if <i>uplo</i> = 'L'), or the upper triangle (if <i>uplo</i> = 'U') of <i>A</i> , including the diagonal, is overwritten.
<i>w</i>	(global). Array of size <i>n</i> . If <i>info</i> = 0, <i>w</i> contains the eigenvalues in the ascending order.
<i>z</i>	(local). Array, global size $n*n$, local size $lld\_z*LOC(jz+n-1)$. The <i>z</i> parameter contains the orthonormal eigenvectors of the matrix <i>A</i> .
<i>work</i> [0]	On exit, returns adequate workspace to allow optimal performance.
<i>rwork</i> [0]	(local) On output, <i>rwork</i> [0] returns workspace required to guarantee completion.
<i>iwork</i> [0]	(local). On return, <i>iwork</i> [0] contains the amount of integer workspace required.
<i>info</i>	(global) If <i>info</i> = 0, the execution is successful. If <i>info</i> < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -entry had an illegal value, then <i>info</i> = -(<i>i</i> *100+ <i>j</i>). If the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> . If <i>info</i> > 0: If <i>info</i> = 1 through <i>n</i> , the <i>i</i> -th eigenvalue did not converge.

```

Include Files

- mkl_scalapack.h

Description

p?heevr computes selected eigenvalues and, optionally, eigenvectors of a complex Hermitian matrix *A* distributed in 2D blockcyclic format by calling the recommended sequence of ScaLAPACK functions.

First, the matrix *A* is reduced to complex Hermitian tridiagonal form. Then, the eigenproblem is solved using the parallel MRRR algorithm. Last, if eigenvectors have been computed, a backtransformation is done.

Upon successful completion, each processor stores a copy of all computed eigenvalues in *w*. The eigenvector matrix *Z* is stored in 2D block-cyclic format distributed over all processors.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

<i>jobz</i>	(global) Specifies whether or not to compute the eigenvectors: = 'N': Compute eigenvalues only. = 'V': Compute eigenvalues and eigenvectors.
<i>range</i>	(global) = 'A': all eigenvalues will be found. = 'V': all eigenvalues in the interval [<i>vl</i> , <i>vu</i>] will be found. = 'I': the <i>il</i> -th through <i>iu</i> -th eigenvalues will be found.
<i>uplo</i>	(global) Specifies whether the upper or lower triangular part of the Hermitian matrix <i>A</i> is stored: = 'U': Upper triangular = 'L': Lower triangular
<i>n</i>	(global) The number of rows and columns of the matrix <i>A</i> . $n \geq 0$

<i>a</i>	Block-cyclic array, global size $n * n$, local size $lld\_a * LOC_c(ja+n-1)$ Contains the local pieces of the Hermitian distributed matrix <i>A</i>. If <i>uplo</i> = 'U', only the upper triangular part of <i>a</i> is used to define the elements of the Hermitian matrix. If <i>uplo</i> = 'L', only the lower triangular part of <i>a</i> is used to define the elements of the Hermitian matrix.
<i>ia</i>	(global) Global row index in the global matrix <i>A</i> that points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix.
<i>ja</i>	(global) Global column index in the global matrix <i>A</i> that points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix.
<i>desca</i>	(global and local) array of size <i>dlen_</i>. (The ScaLAPACK descriptor length is <i>dlen_</i> = 9.) The array descriptor for the distributed matrix <i>a</i>. The descriptor stores details about the 2D block-cyclic storage, see the notes below. If <i>desca</i> is incorrect, <i>p?heevr</i> cannot work correctly. Also note the array alignment requirements specified below
<i>vl</i>	(global) If <i>range</i>='V', the lower bound of the interval to be searched for eigenvalues. Not referenced if <i>range</i> = 'A' or 'I'.
<i>vu</i>	(global) If <i>range</i>='V', the upper bound of the interval to be searched for eigenvalues. Not referenced if <i>range</i> = 'A' or 'I'.
<i>il</i>	(global) If <i>range</i>='I', the index (from smallest to largest) of the smallest eigenvalue to be returned. $il \geq 1$. Not referenced if <i>range</i> = 'A'.
<i>iu</i>	(global) If <i>range</i>='I', the index (from smallest to largest) of the largest eigenvalue to be returned. $\min(il, n) \leq iu \leq n$. Not referenced if <i>range</i> = 'A'.
<i>iz</i>	(global) Global row index in the global matrix <i>Z</i> that points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix.
<i>jz</i>	(global)

Global column index in the global matrix Z that points to the beginning of the submatrix which is to be operated on. It should be set to 1 when operating on a full matrix.

descz

(global and local) array of size *dlen_*.

The array descriptor for the distributed matrix z . *descz*[*ctxt_* - 1] must equal *desca*[*ctxt_* - 1]

work

(local workspace) array of size *lwork*

lwork

(local)

Size of *work* array, must be at least 3.

If only eigenvalues are requested:

$$lwork \geq n + \max(nb * (np00 + 1), nb * 3)$$

If eigenvectors are requested:

$$lwork \geq n + (np00 + mq00 + nb) * nb$$

For definitions of *np00* and *mq00*, see *lrwork*.

For optimal performance, greater workspace is needed, i.e.

$$lwork \geq \max(lwork, nhetrd\_lwork)$$

Where *lwork* is as defined above, and

$$nhetrd\_lwork = n + 2 * (anb + 1) * (4 * nps + 2) + (nps + 1) * nps$$

$$ictxt = desca[ctxt\_ - 1]$$

$$anb = pjlavenv(ictxt, 3, 'PCHETTRD', 'L', 0, 0, 0, 0)$$

$$sqnpc = \text{sqrt}(\text{real}(nprow * npc0l))$$

$$nps = \max(\text{numroc}(n, 1, 0, 0, sqnpc), 2 * anb)$$

If *lwork* = -1, then *lwork* is global input and a workspace query is

assumed; the function only calculates the optimal size for all work arrays.

Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by [pxerbla](#).

rwork

(local workspace) array of size *lrwork*

lrwork

(local)

Size of *rwork*, must be at least 3.

See below for definitions of variables used to define *lrwork*.

If no eigenvectors are requested (*jobz* = 'N') then

$$lrwork \geq 2 + 5 * n + \max(12 * n, nb * (np00 + 1))$$

If eigenvectors are requested (*jobz* = 'V') then the amount of workspace required is:

$$lrwork \geq 2 + 5 * n + \max(18 * n, np00 * mq00 + 2 * nb * nb) +$$

$$(2 + \text{iceil}(neig, nprow * npc0l)) * n$$

NOTE

`iceil(x, y)` is the ceiling of x/y .

Variable definitions:

$neig$ = number of eigenvectors requested

$nb = desca[mb\_ - 1] = desca[nb\_ - 1] = descz[mb\_ - 1] = descz[nb\_ - 1]$

$nn = \max(n, nb, 2)$

$desca[rsrc\_ - 1] = desca[csrc\_ - 1] = descz[rsrc\_ - 1] = descz[csrc\_ - 1] = 0$

$np00 = \text{numroc}(nn, nb, 0, 0, nprow)$

$mq00 = \text{numroc}(\max(neig, nb, 2), nb, 0, 0, npcol)$

`iceil(x, y)` is a ScaLAPACK function returning $\text{ceiling}(x/y)$, and $nprow$ and $npcol$ can be determined by calling the function `blacs_gridinfo`.

If $lrwork = -1$, then $lrwork$ is global input and a workspace query is assumed; the function only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by `pserbla`

iwork

(local workspace) array of size *liwork*

liwork

(local)

size of *iwork*

Let $nnp = \max(n, nprow * npcol + 1, 4)$. Then:

$liwork \geq 12 * nnp + 2 * n$ when the eigenvectors are desired

$liwork \geq 10 * nnp + 2 * n$ when only the eigenvalues have to be computed

If $liwork = -1$, then $liwork$ is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pserbla`

OUTPUT Parameters

a

The lower triangle (if $uplo='L'$) or the upper triangle (if $uplo='U'$) of *a*, including the diagonal, is destroyed.

m

(global)

Total number of eigenvalues found. $0 \leq m \leq n$.

nz

(global)

Total number of eigenvectors computed. $0 \leq nz \leq m$.

The number of columns of *z* that are filled.

If $jobz \neq 'V'$, *nz* is not referenced.

	If $jobz = 'V'$, $nz = m$
w	(global) array of size n On normal exit, the first m entries contain the selected eigenvalues in ascending order.
z	(local) array, global size $n * n$, local size $lld_z * LOC_c(jz+n-1)$ If $jobz = 'V'$, then on normal exit the first m columns of z contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues. If $jobz = 'N'$, then z is not referenced.
$work$	$work[0]$ returns workspace adequate workspace to allow optimal performance.
$rwork$	On return, $rwork[0]$ contains the optimal amount of workspace required for efficient execution. if $jobz='N'$ $rwork[0]$ = optimal amount of workspace required to compute the eigenvalues. if $jobz='V'$ $rwork[0]$ = optimal amount of workspace required to compute eigenvalues and eigenvectors.
$iwork$	On return, $iwork[0]$ contains the amount of integer workspace required.
$info$	(global) = 0: successful exit < 0: If the i -th argument is an array and the j -th entry had an illegal value, then $info = -(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

Application Notes

The distributed submatrices $a(ia:*, ja:*)$ and $z(iz:iz+m-1, jz:jz+n-1)$ must satisfy the following alignment properties:

1. Identical (quadratic) dimension: $desca[m_ - 1] = descz[m_ - 1] = desca[n_ - 1] = descz[n_ - 1]$
2. Quadratic conformal blocking: $desca[mb_ - 1] = desca[nb_ - 1] = descz[mb_ - 1] = descz[nb_ - 1]$,
 $desca[rsrc_ - 1] = descz[rsrc_ - 1]$
3. $\text{mod}(ia-1, mb_a) = \text{mod}(iz-1, mb_z) = 0$

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

Notice revision #20110804

Input Parameters

np = the number of rows local to a given process.

nq = the number of columns local to a given process.

jobz (global) Must be 'N' or 'V'.
 Specifies if it is necessary to compute the eigenvectors:
 If *jobz* = 'N', then only eigenvalues are computed.
 If *jobz* = 'V', then eigenvalues and eigenvectors are computed.

range (global) Must be 'A', 'V', or 'I'.
 If *range* = 'A', all eigenvalues will be found.
 If *range* = 'V', all eigenvalues in the half-open interval $[vl, vu]$ will be found.
 If *range* = 'I', the eigenvalues with indices *il* through *iu* will be found.

<i>uplo</i>	(global) Must be 'U' or 'L'. Specifies whether the upper or lower triangular part of the Hermitian matrix <i>A</i> is stored: If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular part of <i>A</i>. If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular part of <i>A</i>.
<i>n</i>	(global) The number of rows and columns of the matrix <i>A</i> ($n \geq 0$).
<i>a</i>	(local). Block cyclic array of global size $n*n$ and local size $lld\_a*LOCc(ja+n-1)$. On entry, the Hermitian matrix <i>A</i>. If <i>uplo</i> = 'U', only the upper triangular part of <i>A</i> is used to define the elements of the Hermitian matrix. If <i>uplo</i> = 'L', only the lower triangular part of <i>A</i> is used to define the elements of the Hermitian matrix.
<i>ia, ja</i>	(global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> . If <i>desca</i> [<i>ctxt_</i> - 1] is incorrect, p?heevx cannot guarantee correct error reporting.
<i>vl, vu</i>	(global) If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues; not referenced if <i>range</i> = 'A' or 'I'.
<i>il, iu</i>	(global) If <i>range</i> = 'I', the indices of the smallest and largest eigenvalues to be returned. Constraints: $il \geq 1; \min(il, n) \leq iu \leq n$. Not referenced if <i>range</i> = 'A' or 'V'.
<i>abstol</i>	(global). If <i>jobz</i>='V', setting <i>abstol</i> to p?lamch(<i>context</i>, 'U') yields the most orthogonal eigenvectors. The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval [<i>a</i>, <i>b</i>] of width less than or equal to $abstol + eps * \max(a , b)$, where <i>eps</i> is the machine precision. If <i>abstol</i> is less than or equal to zero, then $eps * \text{norm}(T)$ will be used in its place, where $\text{norm}(T)$ is the 1-norm of the tridiagonal matrix obtained by reducing <i>A</i> to tridiagonal form. Eigenvalues are computed most accurately when <i>abstol</i> is set to twice the underflow threshold $2 * p?lamch('S')$, not zero. If this function returns with $((\text{mod}(\text{info}, 2) \neq 0) . \text{or.} (\text{mod}(\text{info}/8, 2) \neq 0))$, indicating that some eigenvalues or eigenvectors did not converge, try setting <i>abstol</i> to $2 * p?lamch('S')$.

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

<i>orfac</i>	(global). Specifies which eigenvectors should be reorthogonalized. Eigenvectors that correspond to eigenvalues which are within $\text{tol}=\text{orfac}*\text{norm}(A)$ of each other are to be reorthogonalized. However, if the workspace is insufficient (see <i>lwork</i>), <i>tol</i> may be decreased until all eigenvectors to be reorthogonalized can be stored in one process. No reorthogonalization will be done if <i>orfac</i> equals zero. A default value of $1.0\text{e-}3$ is used if <i>orfac</i> is negative. <i>orfac</i> should be identical on all processes.
<i>iz, jz</i>	(global) The row and column indices in the global matrix <i>Z</i> indicating the first row and the first column of the submatrix <i>Z</i>, respectively.
<i>descz</i>	(global and local) array of size <i>dlen_</i>. The array descriptor for the distributed matrix <i>Z</i>. <i>descz</i>[<i>ctxt_</i> - 1] must equal <i>desca</i>[<i>ctxt_</i> - 1].
<i>work</i>	(local). Array of size <i>lwork</i>.
<i>lwork</i>	(local) The size of the array <i>work</i>. If only eigenvalues are requested: $lwork \geq n + \max(nb*(np0 + 1), 3)$ If eigenvectors are requested: $lwork \geq n + (np0 + mq0 + nb)*nb$ with $nq0 = \text{numroc}(nn, nb, 0, 0, \text{NPCOL})$. $lwork \geq 5*n + \max(5*nn, np0*mq0 + 2*nb*nb) + \text{iceil}(\text{neig}, \text{NPROW}*\text{NPCOL})*nn$ For optimal performance, greater workspace is needed, that is $lwork \geq \max(lwork, \text{nhetrd\_lwork})$ where <i>lwork</i> is as defined above, and $\text{nhetrd\_lwork} = n + 2*(anb + 1)*(4*nps + 2) + (nps + 1)*nps$ $ictxt = \text{desca}[ctxt\_ - 1]$ $anb = \text{pjlavenv}(ictxt, 3, 'pchettrd', 'L', 0, 0, 0, 0)$ $sqnpc = \text{sqrtd}(\text{dble}(\text{NPROW} * \text{NPCOL}))$ $nps = \max(\text{numroc}(n, 1, 0, 0, sqnpc), 2*anb)$ If <i>lwork</i> = -1, then <i>lwork</i> is global input and a workspace query is assumed; the function only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by <i>pxerbla</i>.
<i>rwork</i>	(local)

lrwork

Workspace array of size *lrwork*.

(local) The size of the array *work*.

See below for definitions of variables used to define *lrwork*.

If no eigenvectors are requested (*jobz* = 'N'), then $lrwork \geq 5*nn+4*n$.

If eigenvectors are requested (*jobz* = 'V'), then the amount of workspace required to guarantee that all eigenvectors are computed is:

$$lrwork \geq 4*n + \max(5*nn, np0*mq0+2*nb*nb) + \text{iceil}(neig, \text{NPROW}*NPCOL)*nn$$

The computed eigenvectors may not be orthogonal if the minimal workspace is supplied and *orfac* is too small. If you want to guarantee orthogonality (at the cost of potentially poor performance) you should add the following values to *lrwork*:

$$(clustersize-1)*n,$$

where *clustersize* is the number of eigenvalues in the largest cluster, where a cluster is defined as a set of close eigenvalues:

$$\{w[k-1], \dots, w[k+clustersize-2] | w[j] \leq w[j-1] + orfac*2*norm(A)\}.$$

Variable definitions:

neig = number of eigenvectors requested;

$$nb = \text{desca}[mb\_ - 1] = \text{desca}[nb\_ - 1] = \text{descz}[mb\_ - 1] = \text{descz}[nb\_ - 1];$$

$$nn = \max(n, NB, 2);$$

$$\text{desca}[rsrc\_ - 1] = \text{desca}[nb\_ - 1] = \text{descz}[rsrc\_ - 1] = \text{descz}[csrc\_ - 1] = 0;$$

$$np0 = \text{numroc}(nn, nb, 0, 0, \text{NPROW});$$

$$mq0 = \text{numroc}(\max(neig, nb, 2), nb, 0, 0, \text{NPCOL});$$

iceil(*x*, *y*) is a ScaLAPACK function returning ceiling(*x*/*y*)

When *lrwork* is too small:

If *lrwork* is too small to guarantee orthogonality, *p?heevx* attempts to maintain orthogonality in the clusters with the smallest spacing between the eigenvalues. If *lrwork* is too small to compute all the eigenvectors requested, no computation is performed and *info*= -23 is returned. Note that when *range*='V', *p?heevx* does not know how many eigenvectors are requested until the eigenvalues are computed. Therefore, when *range*='V' and as long as *lrwork* is large enough to allow *p?heevx* to compute the eigenvalues, *p?heevx* will compute the eigenvalues and as many eigenvectors as it can.

Relationship between workspace, orthogonality and performance:

If $clustersize \geq n/\sqrt{\text{NPROW}*NPCOL}$, then providing enough space to compute all the eigenvectors orthogonally will cause serious degradation in performance. In the limit (that is, $clustersize = n-1$) *p?stein* will perform no better than *?stein* on 1 processor.

For $clustersize = n/\sqrt{NPROW*NPCOL}$ reorthogonalizing all eigenvectors will increase the total execution time by a factor of 2 or more.

For $clustersize > n/\sqrt{NPROW*NPCOL}$ execution time will grow as the square of the cluster size, all other factors remaining equal and assuming enough workspace. Less workspace means less reorthogonalization but faster execution.

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the function only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by `pxerbla`.

iwork

(local) Workspace array.

liwork

(local), size of *iwork*.

$liwork \geq 6 * nnp$

Where: $nnp = \max(n, NPROW*NPCOL+1, 4)$

If $liwork = -1$, then $liwork$ is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

a

On exit, the lower triangle (if $uplo = 'L'$), or the upper triangle (if $uplo = 'U'$) of *A*, including the diagonal, is overwritten.

m

(global) The total number of eigenvalues found; $0 \leq m \leq n$.

nz

(global) Total number of eigenvectors computed. $0 \leq nz \leq m$.

The number of columns of *z* that are filled.

If $jobz \neq 'V'$, *nz* is not referenced.

If $jobz = 'V'$, $nz = m$ unless the user supplies insufficient space and `p?heevx` is not able to detect this before beginning computation. To get all the eigenvectors requested, the user must supply both sufficient space to hold the eigenvectors in *z* ($m \leq descz[n_ - 1]$) and sufficient workspace to compute them. (See *lwork*). `p?heevx` is always able to detect insufficient space without computation unless $range = 'V'$.

w

(global).

Array of size *n*. The first *m* elements contain the selected eigenvalues in ascending order.

z

(local).

Array, global size $n*n$, local size $lld\_z * LOCC(jz+n-1)$.

If *jobz* = 'V', then on normal exit the first *m* columns of *z* contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues. If an eigenvector fails to converge, then that column of *z* contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in *ifail*.

If *jobz* = 'N', then *z* is not referenced.

work[0]

On exit, returns adequate workspace to allow optimal performance.

rwork

(local).

Array of size *lrwork*. On return, *rwork*[0] contains the optimal amount of workspace required for efficient execution.

If *jobz*='N' *rwork*[0] = optimal amount of workspace required to compute eigenvalues efficiently.

If *jobz*='V' *rwork*[0] = optimal amount of workspace required to compute eigenvalues and eigenvectors efficiently with no guarantee on orthogonality.

If *range*='V', it is assumed that all eigenvectors may be required.

iwork[0]

(local)

On return, *iwork*[0] contains the amount of integer workspace required.

ifail

(global)

Array of size *n*.

If *jobz* = 'V', then on normal exit, the first *m* elements of *ifail* are zero. If (mod(*info*,2)≠0) on exit, then *ifail* contains the indices of the eigenvectors that failed to converge.

If *jobz* = 'N', then *ifail* is not referenced.

iclustr

(global)

Array of size 2*NPROW*NPCOL.

This array contains indices of eigenvectors corresponding to a cluster of eigenvalues that could not be reorthogonalized due to insufficient workspace (see *lwork*, *orfac* and *info*). Eigenvectors corresponding to clusters of eigenvalues indexed *iclustr*[2**i* - 2]) to *iclustr*[2**i* - 1], could not be reorthogonalized due to lack of workspace. Hence the eigenvectors corresponding to these clusters may not be orthogonal. *iclustr* is a zero terminated array. (*iclustr*[2**k* - 1]≠0 and *iclustr*[2**k*]=0) if and only if *k* is the number of clusters. *iclustr* is not referenced if *jobz* = 'N'.

gap

(global)

Array of size (NPROW*NPCOL)

This array contains the gap between eigenvalues whose eigenvectors could not be reorthogonalized. The output values in this array correspond to the clusters indicated by the array *iclustr*. As a result, the dot product between eigenvectors corresponding to the *i*-th cluster may be as high as (C*n) / *gap*(*i*) where C is a small constant.

info (global)

If *info* = 0, the execution is successful.

If *info* < 0:

If the *i*-th argument is an array and the *j*-entry had an illegal value, then *info* = -(*i**100+*j*). If the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

If *info* > 0:

If (mod(*info*,2)≠0), then one or more eigenvectors failed to converge. Their indices are stored in *ifail*. Ensure *abstol*=2.0*p?lamch('U')

If (mod(*info*/2,2)≠0), then eigenvectors corresponding to one or more clusters of eigenvalues could not be reorthogonalized because of insufficient workspace. The indices of the clusters are stored in the array *iclustr*.

If (mod(*info*/4,2)≠0), then space limit prevented [p?syevx](#) from computing all of the eigenvectors between *vl* and *vu*. The number of eigenvectors computed is returned in *nz*.

If (mod(*info*/8,2)≠0), then [p?stebz](#) failed to compute eigenvalues. Ensure *abstol*=2.0*p?lamch('U').

See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

p?gesvd

Computes the singular value decomposition of a general matrix, optionally computing the left and/or right singular vectors.

Syntax

```
void psgesvd (char *jobu , char *jobvt , MKL_INT *m , MKL_INT *n , float *a , MKL_INT

Description

The `p?gesvd` function computes the singular value decomposition (SVD) of an m -by- n matrix A , optionally computing the left and/or right singular vectors. The SVD is written

$$A = U \Sigma V^T,$$

where Σ is an m -by- n matrix that is zero except for its $\min(m, n)$ diagonal elements, U is an m -by- m orthogonal matrix, and V is an n -by- n orthogonal matrix. The diagonal elements of Σ are the singular values of A and the columns of U and V are the corresponding right and left singular vectors, respectively. The singular values are returned in array s in decreasing order and only the first $\min(m, n)$ columns of U and rows of $vt = V^T$ are computed.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

mp = number of local rows in A and U

nq = number of local columns in A and VT

$size = \min(m, n)$

$sizeq$ = number of local columns in U

$sizep$ = number of local rows in VT

$jobu$ (global) Specifies options for computing all or part of the matrix U .
If $jobu = 'V'$, the first $size$ columns of U (the left singular vectors) are returned in the array u ;
If $jobu = 'N'$, no columns of U (no left singular vectors) are computed.

$jobvt$ (global)
Specifies options for computing all or part of the matrix V^T .
If $jobvt = 'V'$, the first $size$ rows of V^T (the right singular vectors) are returned in the array vt ;
If $jobvt = 'N'$, no rows of V^T (no right singular vectors) are computed.

m (global) The number of rows of the matrix A ($m \geq 0$).

n (global) The number of columns in A ($n \geq 0$).

a (local).

Block cyclic array, global size (m, n) , local size (mp, nq) .

ia, ja

(global) The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively.

desca

(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix A .

iu, ju

(global) The row and column indices in the global matrix U indicating the first row and the first column of the submatrix U , respectively.

descu

(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix U .

ivt, jvt

(global) The row and column indices in the global matrix VT indicating the first row and the first column of the submatrix VT , respectively.

descvt

(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix VT .

work

(local).

Workspace array of size *lwork*

lwork

(local) The size of the array *work*;

$lwork > 2 + 6 * sizeb + \max(watobd, wbdto svd),$

where $sizeb = \max(m, n)$, and *watobd* and *wbdto svd* refer, respectively, to the workspace required to bidiagonalize the matrix A and to go from the bidiagonal matrix to the singular value decomposition $USVT$.

For *watobd*, the following holds:

$watobd = \max(\max(wp?lange, wp?gebrd), \max(wp?lared2d, wp?lared1d)),$

where *wp?lange*, *wp?lared1d*, *wp?lared2d*, *wp?gebrd* are the workspaces required respectively for the subprograms *p?lange*, *p?lared1d*, *p?lared2d*, *p?gebrd*. Using the standard notation

$mp = \text{numroc}(m, mb, MYROW, desca[ctxt\_ - 1], NPROW),$

$nq = \text{numroc}(n, nb, MYCOL, desca[lld\_ - 1], NPCOL),$

the workspaces required for the above subprograms are

$wp?lange = mp,$

$wp?lared1d = nq0,$

$wp?lared2d = mp0,$

$wp?gebrd = nb * (mp + nq + 1) + nq,$

where *nq0* and *mp0* refer, respectively, to the values obtained at *MYCOL* = 0 and *MYROW* = 0. In general, the upper limit for the workspace is given by a workspace required on processor (0,0):

$watobd \leq nb * (mp0 + nq0 + 1) + nq0.$

In case of a homogeneous process grid this upper limit can be used as an estimate of the minimum workspace for every processor.

For *wbdto svd*, the following holds:

$$wbd\text{tosvd} = \text{size} * (\text{wantu} * nru + \text{wantvt} * ncvt) + \max(w?bdsqr, \max(\text{wantu} * wp?ormbrqln, \text{wantvt} * wp?ormbrprt)),$$

where

$\text{wantu}(\text{wantvt}) = 1$, if left/right singular vectors are wanted, and $\text{wantu}(\text{wantvt}) = 0$, otherwise. $w?bdsqr$, $wp?ormbrqln$, and $wp?ormbrprt$ refer respectively to the workspace required for the subprograms $?bdsqr$, $p?ormbr(qln)$, and $p?ormbr(prt)$, where qln and prt are the values of the arguments *vect*, *side*, and *trans* in the call to $p?ormbr$. nru is equal to the local number of rows of the matrix U when distributed 1-dimensional "column" of processes. Analogously, $ncvt$ is equal to the local number of columns of the matrix VT when distributed across 1-dimensional "row" of processes. Calling the LAPACK procedure $?bdsqr$ requires

$$w?bdsqr = \max(1, 2 * \text{size} + (2 * \text{size} - 4) * \max(\text{wantu}, \text{wantvt}))$$

on every processor. Finally,

$$wp?ormbrqln = \max((nb * (nb - 1)) / 2, (\text{sizeq} + mp) * nb) + nb * nb,$$

$$wp?ormbrprt = \max((mb * (mb - 1)) / 2, (\text{sizep} + nq) * mb) + mb * mb,$$

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the function only calculates the minimum size for the work array. The required workspace is returned as the first element of *work* and no error message is issued by $pxerbla$.

rwork

Workspace array of size $1 + 4 * \text{sizeb}$. Not used for $psgesvd$ and $pdgesvd$.

Output Parameters

a

On exit, the contents of *a* are destroyed.

s

(global).

Array of size *size*.

Contains the singular values of A sorted so that $s(i) \geq s(i+1)$.

u

(local).

local size $mp * \text{sizeq}$, global size $m * \text{size}$

If $jobu = 'V'$, *u* contains the first $\min(m, n)$ columns of U .

If $jobu = 'N'$ or $'O'$, *u* is not referenced.

vt

(local).

local size (sizep, nq) , global size (size, n)

If $jobvt = 'V'$, *vt* contains the first *size* rows of V^T . If $jobu = 'N'$, *vt* is not referenced.

work

On exit, if $info = 0$, then $work[0]$ returns the required minimal size of *lwork*.

rwork

On exit, if $info = 0$, then $rwork[0]$ returns the required size of *rwork*.

info

(global)

If $info = 0$, the execution is successful.

If $info < 0$, If $info = -i$, the i th parameter had an illegal value.

If $info > 0$ i , then if $?bdsqr$ did not converge,

If $info = \min(m, n) + 1$, then $p?gesvd$ has detected heterogeneity by finding that eigenvalues were not identical across the process grid. In this case, the accuracy of the results from $p?gesvd$ cannot be guaranteed.

See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

p?sygvx

Computes selected eigenvalues and, optionally, eigenvectors of a real generalized symmetric definite eigenproblem.

Syntax

```
void pssygvx (MKL_INT *ibtype , char *jobz , char *range , char *uplo , MKL_INT *n ,
float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *b , MKL_INT *ib ,

Description

The `p?sygvx` function computes all the eigenvalues, and optionally, the eigenvectors of a real generalized symmetric-definite eigenproblem, of the form

$$\text{sub}(A) * x = \lambda * \text{sub}(B) * x, \text{sub}(A) \text{ sub}(B) * x = \lambda * x, \text{ or } \text{sub}(B) * \text{sub}(A) * x = \lambda * x.$$

Here x denotes eigen vectors, λ (*lambda*) denotes eigenvalues, $\text{sub}(A)$ denoting $A(ia:ia+n-1, ja:ja+n-1)$ is assumed to be symmetric, and $\text{sub}(B)$ denoting $B(ib:ib+n-1, jb:jb+n-1)$ is also positive definite.

Notice revision #20110804

Input Parameters

<i>ibtype</i>	(global) Must be 1 or 2 or 3. Specifies the problem type to be solved: If <i>ibtype</i> = 1, the problem type is $\text{sub}(A) * x = \text{lambda} * \text{sub}(B) * x$; If <i>ibtype</i> = 2, the problem type is $\text{sub}(A) * \text{sub}(B) * x = \text{lambda} * x$; If <i>ibtype</i> = 3, the problem type is $\text{sub}(B) * \text{sub}(A) * x = \text{lambda} * x$.
<i>jobz</i>	(global) Must be 'N' or 'V'. If <i>jobz</i> = 'N', then compute eigenvalues only. If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.
<i>range</i>	(global) Must be 'A' or 'V' or 'I'. If <i>range</i> = 'A', the function computes all eigenvalues. If <i>range</i> = 'V', the function computes eigenvalues in the interval: [<i>vl</i>, <i>vu</i>] If <i>range</i> = 'I', the function computes eigenvalues with indices <i>il</i> through <i>iu</i>.
<i>uplo</i>	(global) Must be 'U' or 'L'. If <i>uplo</i> = 'U', arrays <i>a</i> and <i>b</i> store the upper triangles of $\text{sub}(A)$ and $\text{sub}(B)$; If <i>uplo</i> = 'L', arrays <i>a</i> and <i>b</i> store the lower triangles of $\text{sub}(A)$ and $\text{sub}(B)$.
<i>n</i>	(global) The order of the matrices $\text{sub}(A)$ and $\text{sub}(B)$, $n \geq 0$.
<i>a</i>	(local) Pointer into the local memory to an array of size $\text{ld\_a} * \text{LOCc}(ja+n-1)$. On entry, this array contains the local pieces of the <i>n</i>-by-<i>n</i> symmetric distributed matrix $\text{sub}(A)$. If <i>uplo</i> = 'U', the leading <i>n</i>-by-<i>n</i> upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix. If <i>uplo</i> = 'L', the leading <i>n</i>-by-<i>n</i> lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the matrix.
<i>ia, ja</i>	(global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.

<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> . If <i>desca[ctxt_ - 1]</i> is incorrect, <i>p?sygvx</i> cannot guarantee correct error reporting.
<i>b</i>	(local). Pointer into the local memory to an array of size <i>lld_b*LOCc(jb+n-1)</i> . On entry, this array contains the local pieces of the <i>n</i> -by- <i>n</i> symmetric distributed matrix sub(<i>B</i>). If <i>uplo</i> = 'U', the leading <i>n</i> -by- <i>n</i> upper triangular part of sub(<i>B</i>) contains the upper triangular part of the matrix. If <i>uplo</i> = 'L', the leading <i>n</i> -by- <i>n</i> lower triangular part of sub(<i>A</i>) contains the lower triangular part of the matrix.
<i>ib, jb</i>	(global) The row and column indices in the global matrix <i>B</i> indicating the first row and the first column of the submatrix <i>B</i> , respectively.
<i>descb</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>B</i> . <i>descb[ctxt_ - 1]</i> must be equal to <i>desca[ctxt_ - 1]</i> .
<i>vl, vu</i>	(global) If <i>range</i> = 'V', the lower and upper bounds of the interval to be searched for eigenvalues. If <i>range</i> = 'A' or 'I', <i>vl</i> and <i>vu</i> are not referenced.
<i>il, iu</i>	(global) If <i>range</i> = 'I', the indices in ascending order of the smallest and largest eigenvalues to be returned. Constraint: $il \geq 1, \min(il, n) \leq iu \leq n$ If <i>range</i> = 'A' or 'V', <i>il</i> and <i>iu</i> are not referenced.
<i>abstol</i>	(global) If <i>jobz</i> ='V', setting <i>abstol</i> to <i>p?lamch(context, 'U')</i> yields the most orthogonal eigenvectors. The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a, b]$ of width less than or equal to $abstol + eps * \max(a , b),$ where <i>eps</i> is the machine precision. If <i>abstol</i> is less than or equal to zero, then <i>eps*norm(T)</i> will be used in its place, where <i>norm(T)</i> is the 1-norm of the tridiagonal matrix obtained by reducing <i>A</i> to tridiagonal form. Eigenvalues will be computed most accurately when <i>abstol</i> is set to twice the underflow threshold <i>2*p?lamch('S')</i> not zero. If this function returns with $((\text{mod}(\text{info}, 2) \neq 0) \text{ or } (\text{mod}(\text{info}/8, 2) \neq 0))$, indicating that some eigenvalues or eigenvectors did not converge, try setting <i>abstol</i> to <i>2*p?lamch('S')</i> .

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

<i>orfac</i>	(global). Specifies which eigenvectors should be reorthogonalized. Eigenvectors that correspond to eigenvalues which are within $\text{tol}=\text{orfac}*\text{norm}(A)$ of each other are to be reorthogonalized. However, if the workspace is insufficient (see <i>lwork</i>), <i>tol</i> may be decreased until all eigenvectors to be reorthogonalized can be stored in one process. No reorthogonalization will be done if <i>orfac</i> equals zero. A default value of 1.0e-3 is used if <i>orfac</i> is negative. <i>orfac</i> should be identical on all processes.
<i>iz, jz</i>	(global) The row and column indices in the global matrix <i>Z</i> indicating the first row and the first column of the submatrix <i>Z</i> , respectively.
<i>descz</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>Z</i> . <i>descz[ctxt_ - 1]</i> must equal <i>desca[ctxt_ - 1]</i> .
<i>work</i>	(local) Workspace array of size <i>lwork</i>
<i>lwork</i>	(local) Size of the array <i>work</i> . See below for definitions of variables used to define <i>lwork</i> . If no eigenvectors are requested (<i>jobz</i> = 'N'), then $\text{lwork} \geq 5*n + \max(5*nn, \text{NB}*(\text{np0} + 1))$. If eigenvectors are requested (<i>jobz</i> = 'V'), then the amount of workspace required to guarantee that all eigenvectors are computed is: $\text{lwork} \geq 5*n + \max(5*nn, \text{np0}*mq0 + 2*nb*nb) + \text{iceil}(\text{neig}, \text{NPROW}*NPCOL)*nn$. The computed eigenvectors may not be orthogonal if the minimal workspace is supplied and <i>orfac</i> is too small. If you want to guarantee orthogonality at the cost of potentially poor performance you should add the following to <i>lwork</i> : $(\text{clustersize}-1)*n$, where <i>clustersize</i> is the number of eigenvalues in the largest cluster, where a cluster is defined as a set of close eigenvalues: $\{w[k - 1], \dots, w[k+\text{clustersize} - 2] w[j] \leq w[j - 1] + \text{orfac}*2*\text{norm}(A)\}$ Variable definitions: <i>neig</i> = number of eigenvectors requested, $\text{nb} = \text{desca}[\text{mb}_ - 1] = \text{desca}[\text{nb}_ - 1] = \text{descz}[\text{mb}_ - 1] = \text{descz}[\text{nb}_ - 1]$, $\text{nn} = \max(n, \text{nb}, 2)$, $\text{desca}[\text{rsrc}_ - 1] = \text{desca}[\text{nb}_ - 1] = \text{descz}[\text{rsrc}_ - 1] = \text{descz}[\text{csrc}_ - 1] = 0$,

```
np0 = numroc(nn, nb, 0, 0, NPROW),
```

```
mq0 = numroc(max(neig, nb, 2), nb, 0, 0, NPCOL)
```

`iceil(x, y)` is a ScaLAPACK function returning $\text{ceiling}(x/y)$

If *lwork* is too small to guarantee orthogonality, `p?syevx` attempts to maintain orthogonality in the clusters with the smallest spacing between the eigenvalues.

If *lwork* is too small to compute all the eigenvectors requested, no computation is performed and *info*= -23 is returned.

Note that when *range*='V', number of requested eigenvectors are not known until the eigenvalues are computed. In this case and if *lwork* is large enough to compute the eigenvalues, `p?sygvx` computes the eigenvalues and as many eigenvectors as possible.

Greater performance can be achieved if adequate workspace is provided. In some situations, performance can decrease as the provided workspace increases above the workspace amount shown below:

```
lwork ≥ max(lwork, 5*n + nsytrd_lwopt, nsygst_lwopt), where
```

lwork, as defined previously, depends upon the number of eigenvectors requested, and

```
nsytrd_lwopt = n + 2*(anb+1)*(4*nps+2) + (nps+3)*nps
```

```
nsygst_lwopt = 2*np0*nb + nq0*nb + nb*nb
```

```
anb = pjlaenv(desca[ctxt_ - 1], 3, p?syttrd ' ', 'L', 0, 0, 0, 0)
```

```
sqnpc = int(sqrt(dble(NPROW * NPCOL)))
```

```
nps = max(numroc(n, 1, 0, 0, sqnpc), 2*anb)
```

```
NB = desca[mb_ - 1]
```

```
np0 = numroc(n, nb, 0, 0, NPROW)
```

```
nq0 = numroc(n, nb, 0, 0, NPCOL)
```

`numroc` is a ScaLAPACK tool functions;

`pjlaenv` is a ScaLAPACK environmental inquiry function

`MYROW`, `MYCOL`, `NPROW` and `NPCOL` can be determined by calling the function `blacs_gridinfo`.

For large *n*, no extra workspace is needed, however the biggest boost in performance comes for small *n*, so it is wise to provide the extra workspace (typically less than a Megabyte per process).

If $\text{clustersize} \geq n/\sqrt{\text{NPROW} \times \text{NPCOL}}$, then providing enough space to compute all the eigenvectors orthogonally will cause serious degradation in performance. At the limit (that is, $\text{clustersize} = n-1$) `p?stein` will perform no better than `?stein` on a single processor.

For $\text{clustersize} = n/\sqrt{\text{NPROW} \times \text{NPCOL}}$ reorthogonalizing all eigenvectors will increase the total execution time by a factor of 2 or more.

For $clustersize > n/\sqrt{NPROW * NPCOL}$ execution time will grow as the square of the cluster size, all other factors remaining equal and assuming enough workspace. Less workspace means less reorthogonalization but faster execution.

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the function only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by `pxerbla`.

iwork

(local) Workspace array.

liwork

(local) , size of *iwork*.

$liwork \geq 6 * nnp$

Where:

$nnp = \max(n, NPROW * NPCOL + 1, 4)$

If $liwork = -1$, then $liwork$ is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

a

On exit,

If $jobz = 'V'$, and if $info = 0$, $\text{sub}(A)$ contains the distributed matrix Z of eigenvectors. The eigenvectors are normalized as follows:

for $ibtype = 1$ or 2 , $Z^T * \text{sub}(B) * Z = I$;

for $ibtype = 3$, $Z^T * \text{inv}(\text{sub}(B)) * Z = I$.

If $jobz = 'N'$, then on exit the upper triangle (if $uplo = 'U'$) or the lower triangle (if $uplo = 'L'$) of $\text{sub}(A)$, including the diagonal, is destroyed.

b

On exit, if $info \leq n$, the part of $\text{sub}(B)$ containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization $\text{sub}(B) = U^T * U$ or $\text{sub}(B) = L * L^T$.

m

(global) The total number of eigenvalues found, $0 \leq m \leq n$.

nz

(global)

Total number of eigenvectors computed. $0 \leq nz \leq m$. The number of columns of z that are filled.

If $jobz \neq 'V'$, nz is not referenced.

If $jobz = 'V'$, $nz = m$ unless the user supplies insufficient space and `p?sygvx` is not able to detect this before beginning computation. To get all the eigenvectors requested, the user must supply both sufficient space to hold the eigenvectors in z ($m \leq \text{descz}(n\_)$) and sufficient workspace to compute them. (See *lwork* below.) `p?sygvx` is always able to detect insufficient space without computation unless $range = 'V'$.

w

(global)

Array of size n . On normal exit, the first m entries contain the selected eigenvalues in ascending order.

z

(local).

global size $n*n$, local size $lld\_z*LOCc(jz+n-1)$.

If $jobz = 'V'$, then on normal exit the first m columns of z contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues. If an eigenvector fails to converge, then that column of z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in *ifail*.

If $jobz = 'N'$, then z is not referenced.

work

If $jobz='N'$ $work[0]$ = optimal amount of workspace required to compute eigenvalues efficiently

If $jobz = 'V'$ $work[0]$ = optimal amount of workspace required to compute eigenvalues and eigenvectors efficiently with no guarantee on orthogonality.

If $range='V'$, it is assumed that all eigenvectors may be required.

ifail

(global)

Array of size n .

ifail provides additional information when $info \neq 0$

If $(mod(info/16,2) \neq 0)$ then $ifail[0]$ indicates the order of the smallest minor which is not positive definite. If $(mod(info,2) \neq 0)$ on exit, then *ifail* contains the indices of the eigenvectors that failed to converge.

If neither of the above error conditions hold and $jobz = 'V'$, then the first m elements of *ifail* are set to zero.

iclustr

(global)

Array of size $(2*NPROW*NPCOL)$. This array contains indices of eigenvectors corresponding to a cluster of eigenvalues that could not be reorthogonalized due to insufficient workspace (see *lwork*, *orfac* and *info*). Eigenvectors corresponding to clusters of eigenvalues indexed $iclustr[2*i - 2]$ to $iclustr[2*i - 1]$, could not be reorthogonalized due to lack of workspace. Hence the eigenvectors corresponding to these clusters may not be orthogonal. *iclustr* is a zero terminated array.

$(iclustr[2*k - 1] \neq 0 \text{ and } iclustr[2*k] = 0)$ if and only if k is the number of clusters *iclustr* is not referenced if $jobz = 'N'$.

gap

(global)

Array of size $NPROW*NPCOL$. This array contains the gap between eigenvalues whose eigenvectors could not be reorthogonalized. The output values in this array correspond to the clusters indicated by the array *iclustr*. As a result, the dot product between eigenvectors corresponding to the i -th cluster may be as high as $(C*n)/gap[i - 1]$, where C is a small constant.

info

(global)

If $info = 0$, the execution is successful.

If $info < 0$: the i -th argument is an array and the j -entry had an illegal value, then $info = -(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

If $info > 0$:

If $(\text{mod}(info, 2) \neq 0)$, then one or more eigenvectors failed to converge. Their indices are stored in *ifail*.

If $(\text{mod}(info, 2, 2) \neq 0)$, then eigenvectors corresponding to one or more clusters of eigenvalues could not be reorthogonalized because of insufficient workspace. The indices of the clusters are stored in the array *iclustr*.

If $(\text{mod}(info/4, 2) \neq 0)$, then space limit prevented *p?sygvx* from computing all of the eigenvectors between vl and vu . The number of eigenvectors computed is returned in *nz*.

If $(\text{mod}(info/8, 2) \neq 0)$, then *p?stebz* failed to compute eigenvalues.

If $(\text{mod}(info/16, 2) \neq 0)$, then B was not positive definite. *ifail(1)* indicates the order of the smallest minor which is not positive definite.

See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

p?hegvx

Computes selected eigenvalues and, optionally, eigenvectors of a complex generalized Hermitian positive-definite eigenproblem.

Syntax

```
void pchegvx (MKL_INT *ibtype , char *jobz , char *range , char *uplo , MKL_INT *n ,

Description

The *p?hegvx* function computes all the eigenvalues, and optionally, the eigenvectors of a complex generalized Hermitian positive-definite eigenproblem, of the form

$$\text{sub}(A) * x = \lambda * \text{sub}(B) * x, \quad \text{sub}(A) * \text{sub}(B) * x = \lambda * x, \quad \text{or} \quad \text{sub}(B) * \text{sub}(A) * x = \lambda * x.$$

Here $\text{sub}(A)$ denoting $A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$ and $\text{sub}(B)$ are assumed to be Hermitian and $\text{sub}(B)$ denoting $B(\text{ib}:\text{ib}+n-1, \text{jb}:\text{jb}+n-1)$ is also positive definite.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. Notice revision #20110804

Input Parameters

<i>ibtype</i>	(global) Must be 1 or 2 or 3. Specifies the problem type to be solved: If <i>ibtype</i> = 1, the problem type is $\text{sub}(A) * x = \text{lambda} * \text{sub}(B) * x;$ If <i>ibtype</i> = 2, the problem type is $\text{sub}(A) * \text{sub}(B) * x = \text{lambda} * x;$ If <i>ibtype</i> = 3, the problem type is $\text{sub}(B) * \text{sub}(A) * x = \text{lambda} * x.$
<i>jobz</i>	(global) Must be 'N' or 'V'. If <i>jobz</i> = 'N', then compute eigenvalues only. If <i>jobz</i> = 'V', then compute eigenvalues and eigenvectors.
<i>range</i>	(global) Must be 'A' or 'V' or 'I'. If <i>range</i> = 'A', the function computes all eigenvalues. If <i>range</i> = 'V', the function computes eigenvalues in the interval: [<i>vl</i>, <i>vu</i>] If <i>range</i> = 'I', the function computes eigenvalues with indices <i>il</i> through <i>iu</i>.
<i>uplo</i>	(global) Must be 'U' or 'L'. If <i>uplo</i> = 'U', arrays <i>a</i> and <i>b</i> store the upper triangles of $\text{sub}(A)$ and $\text{sub}(B)$; If <i>uplo</i> = 'L', arrays <i>a</i> and <i>b</i> store the lower triangles of $\text{sub}(A)$ and $\text{sub}(B)$.
<i>n</i>	(global) The order of the matrices $\text{sub}(A)$ and $\text{sub}(B)$ ($n \geq 0$).
<i>a</i>	(local)

Pointer into the local memory to an array of size $lld\_a * LOCC(ja+n-1)$. On entry, this array contains the local pieces of the n -by- n Hermitian distributed matrix $sub(A)$. If $uplo = 'U'$, the leading n -by- n upper triangular part of $sub(A)$ contains the upper triangular part of the matrix. If $uplo = 'L'$, the leading n -by- n lower triangular part of $sub(A)$ contains the lower triangular part of the matrix.

ia, ja

(global)

The row and column indices in the global matrix A indicating the first row and the first column of the submatrix A , respectively.

desca

(global and local) array of size $dlen\_$.

The array descriptor for the distributed matrix A . If $desca[ctxt\_ - 1]$ is incorrect, `p?hegvx` cannot guarantee correct error reporting.

b

(local).

Pointer into the local memory to an array of size $lld\_b * LOCC(jb+n-1)$. On entry, this array contains the local pieces of the n -by- n Hermitian distributed matrix $sub(B)$.

If $uplo = 'U'$, the leading n -by- n upper triangular part of $sub(B)$ contains the upper triangular part of the matrix.

If $uplo = 'L'$, the leading n -by- n lower triangular part of $sub(B)$ contains the lower triangular part of the matrix.

ib, jb

(global)

The row and column indices in the global matrix B indicating the first row and the first column of the submatrix B , respectively.

descb

(global and local) array of size $dlen\_$.

The array descriptor for the distributed matrix B . $descb[ctxt\_ - 1]$ must be equal to $desca[ctxt\_ - 1]$.

vl, vu

(global)

If $range = 'V'$, the lower and upper bounds of the interval to be searched for eigenvalues.

If $range = 'A'$ or $'I'$, vl and vu are not referenced.

il, iu

(global)

If $range = 'I'$, the indices in ascending order of the smallest and largest eigenvalues to be returned. Constraint: $il \geq 1$, $\min(il, n) \leq iu \leq n$

If $range = 'A'$ or $'V'$, il and iu are not referenced.

abstol

(global)

If $jobz = 'V'$, setting *abstol* to `p?lamch(context, 'U')` yields the most orthogonal eigenvectors.

The absolute error tolerance for the eigenvalues. An approximate eigenvalue is accepted as converged when it is determined to lie in an interval $[a, b]$ of width less than or equal to

$abstol + eps * \max(|a|, |b|)$,

where eps is the machine precision. If $abstol$ is less than or equal to zero, then $eps * \text{norm}(\mathbb{T})$ will be used in its place, where $\text{norm}(\mathbb{T})$ is the 1-norm of the tridiagonal matrix obtained by reducing A to tridiagonal form.

Eigenvalues will be computed most accurately when $abstol$ is set to twice the underflow threshold $2 * p?lamch('S')$ not zero. If this function returns with $((\text{mod}(\text{info}, 2) \neq 0) .or. * (\text{mod}(\text{info}/8, 2) \neq 0))$, indicating that some eigenvalues or eigenvectors did not converge, try setting $abstol$ to $2 * p?lamch('S')$.

NOTE

$\text{mod}(x, y)$ is the integer remainder of x/y .

orfac

(global).

Specifies which eigenvectors should be reorthogonalized. Eigenvectors that correspond to eigenvalues which are within $tol = orfac * \text{norm}(A)$ of each other are to be reorthogonalized. However, if the workspace is insufficient (see *lwork*), tol may be decreased until all eigenvectors to be reorthogonalized can be stored in one process. No reorthogonalization will be done if *orfac* equals zero. A default value of 1.0E-3 is used if *orfac* is negative. *orfac* should be identical on all processes.

iz, jz

(global) The row and column indices in the global matrix Z indicating the first row and the first column of the submatrix Z , respectively.

descz

(global and local) array of size *dlen_*. The array descriptor for the distributed matrix Z . *descz[ctxt_ - 1]* must equal *desca[ctxt_ - 1]*.

work

(local)

Workspace array of size *lwork*

lwork

(local).

The size of the array *work*.

If only eigenvalues are requested:

$$lwork \geq n + \max(\text{NB} * (\text{np0} + 1), 3)$$

If eigenvectors are requested:

$$lwork \geq n + (\text{np0} + \text{mq0} + \text{NB}) * \text{NB}$$

with $\text{mq0} = \text{numroc}(\text{nn}, \text{NB}, 0, 0, \text{NPCOL})$.

For optimal performance, greater workspace is needed, that is

$$lwork \geq \max(lwork, n, \text{nhetrd\_lwopt}, \text{nhegst\_lwopt})$$

where *lwork* is as defined above, and

$$\text{nhetrd\_lwork} = 2 * (\text{anb} + 1) * (4 * \text{nps} + 2) + (\text{nps} + 1) * \text{nps};$$

$$\text{nhegst\_lwopt} = 2 * \text{np0} * \text{nb} + \text{nq0} * \text{nb} + \text{nb} * \text{nb}$$

$$\text{nb} = \text{desca}[\text{mb}_ - 1]$$

$$\text{np0} = \text{numroc}(n, \text{nb}, 0, 0, \text{NPROW})$$

```

nq0 = numroc(n, nb, 0, 0, NPCOL)
ictxt = desca[ctxt_ - 1]
anb = pjlavenv(ictxt, 3, 'p?hettrd', 'L', 0, 0, 0, 0)
sqnpc = sqrt(dble(NPROW * NPCOL))
nps = max(numroc(n, 1, 0, 0, sqnpc), 2*anb)

```

numroc is a ScaLAPACK tool functions;

pjlavenv is a ScaLAPACK environmental inquiry function MYROW, MYCOL, NPROW and NPCOL can be determined by calling the function blacs_gridinfo.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the function only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by pxxerbla.

rwork

(local)

Workspace array of size *lwork*.

lrwork

(local) The size of the array *rwork*.

See below for definitions of variables used to define *lrwork*.

If no eigenvectors are requested (*jobz* = 'N'), then $lrwork \geq 5*nn+4*n$

If eigenvectors are requested (*jobz* = 'V'), then the amount of workspace required to guarantee that all eigenvectors are computed is:

$$lrwork \geq 4*n + \max(5*nn, np0*mq0) + \text{iceil}(neig, NPROW*NPCOL)*nn$$

The computed eigenvectors may not be orthogonal if the minimal workspace is supplied and *orfac* is too small. If you want to guarantee orthogonality (at the cost of potentially poor performance) you should add the following value to *lrwork*:

$$(clustersize-1)*n,$$

where *clustersize* is the number of eigenvalues in the largest cluster, where a cluster is defined as a set of close eigenvalues:

$$\{w[k-1], \dots, w[k+clustersize-2] | w[j] \leq w[j-1] + orfac*2*norm(A)\}$$

Variable definitions:

neig = number of eigenvectors requested;

$$nb = desca[mb_ - 1] = desca[nb_ - 1] = descz[mb_ - 1] = descz[nb_ - 1];$$

$$nn = \max(n, nb, 2);$$

$$desca[rsrc_ - 1] = desca[nb_ - 1] = descz[rsrc_ - 1] = descz[csrc_ - 1] = 0;$$

$$np0 = \text{numroc}(nn, nb, 0, 0, NPROW);$$

$$mq0 = \text{numroc}(\max(neig, nb, 2), nb, 0, 0, NPCOL);$$

iceil(*x*, *y*) is a ScaLAPACK function returning ceiling(*x*/*y*).

When *lwork* is too small:

If *lwork* is too small to guarantee orthogonality, p?hegvx attempts to maintain orthogonality in the clusters with the smallest spacing between the eigenvalues.

If *lwork* is too small to compute all the eigenvectors requested, no computation is performed and *info*= -25 is returned. Note that when *range*='V', p?hegvx does not know how many eigenvectors are requested until the eigenvalues are computed. Therefore, when *range*='V' and as long as *lwork* is large enough to allow p?hegvx to compute the eigenvalues, p?hegvx will compute the eigenvalues and as many eigenvectors as it can.

Relationship between workspace, orthogonality & performance:

If $clustersize > n/\sqrt{NPROW \cdot NPCOL}$, then providing enough space to compute all the eigenvectors orthogonally will cause serious degradation in performance. In the limit (that is, $clustersize = n-1$) p?stein will perform no better than ?stein on 1 processor.

For $clustersize = n/\sqrt{NPROW \cdot NPCOL}$ reorthogonalizing all eigenvectors will increase the total execution time by a factor of 2 or more.

For $clustersize > n/\sqrt{NPROW \cdot NPCOL}$ execution time will grow as the square of the cluster size, all other factors remaining equal and assuming enough workspace. Less workspace means less reorthogonalization but faster execution.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the function only calculates the size required for optimal performance for all work arrays. Each of these values is returned in the first entry of the corresponding work arrays, and no error message is issued by p?xerbla.

iwork

(local) Workspace array.

liwork

(local) , size of *iwork*.

$liwork \geq 6 * nnp$

Where: $nnp = \max(n, NPROW \cdot NPCOL + 1, 4)$

If *liwork* = -1, then *liwork* is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by p?xerbla.

Output Parameters

a

On exit, if *jobz* = 'V', then if *info* = 0, sub(A) contains the distributed matrix *Z* of eigenvectors.

The eigenvectors are normalized as follows:

If *ibtype* = 1 or 2, then $Z^H \cdot \text{sub}(B) \cdot Z = i$;

If *ibtype* = 3, then $Z^H \cdot \text{inv}(\text{sub}(B)) \cdot Z = i$.

If *jobz* = 'N', then on exit the upper triangle (if *uplo*='U') or the lower triangle (if *uplo*='L') of sub(A), including the diagonal, is destroyed.

<i>b</i>	On exit, if $info \leq n$, the part of $\text{sub}(B)$ containing the matrix is overwritten by the triangular factor U or L from the Cholesky factorization $\text{sub}(B) = U^H * U$, or $\text{sub}(B) = L * L^H$.
<i>m</i>	(global) The total number of eigenvalues found, $0 \leq m \leq n$.
<i>nz</i>	(global) Total number of eigenvectors computed. $0 < nz < m$. The number of columns of z that are filled. If $jobz \neq 'V'$, nz is not referenced. If $jobz = 'V'$, $nz = m$ unless the user supplies insufficient space and <code>p?hegvx</code> is not able to detect this before beginning computation. To get all the eigenvectors requested, the user must supply both sufficient space to hold the eigenvectors in z ($m \leq \text{descz}[n_ - 1]$) and sufficient workspace to compute them. (See <i>lwork</i> below.) The function <code>p?hegvx</code> is always able to detect insufficient space without computation unless $range = 'V'$.
<i>w</i>	(global) Array of size n . On normal exit, the first m entries contain the selected eigenvalues in ascending order.
<i>z</i>	(local). global size $n * n$, local size $lld\_z * LOcc(jz + n - 1)$. If $jobz = 'V'$, then on normal exit the first m columns of z contain the orthonormal eigenvectors of the matrix corresponding to the selected eigenvalues. If an eigenvector fails to converge, then that column of z contains the latest approximation to the eigenvector, and the index of the eigenvector is returned in <i>ifail</i> . If $jobz = 'N'$, then z is not referenced.
<i>work</i>	On exit, $work[0]$ returns the optimal amount of workspace.
<i>rwork</i>	On exit, $rwork[0]$ contains the amount of workspace required for optimal efficiency If $jobz = 'N'$ $rwork[0]$ = optimal amount of workspace required to compute eigenvalues efficiently If $jobz = 'V'$ $rwork[0]$ = optimal amount of workspace required to compute eigenvalues and eigenvectors efficiently with no guarantee on orthogonality. If $range = 'V'$, it is assumed that all eigenvectors may be required when computing optimal workspace.
<i>ifail</i>	(global) Array of size n . <i>ifail</i> provides additional information when $info \neq 0$ If $(\text{mod}(\text{info}/16, 2) \neq 0)$, then $ifail[0]$ indicates the order of the smallest minor which is not positive definite. If $(\text{mod}(\text{info}, 2) \neq 0)$ on exit, then $ifail[0]$ contains the indices of the eigenvectors that failed to converge.

If neither of the above error conditions are held, and $jobz = 'V'$, then the first m elements of *ifail* are set to zero.

iclustr

(global)

Array of size $(2*NPROW*NPCOL)$. This array contains indices of eigenvectors corresponding to a cluster of eigenvalues that could not be reorthogonalized due to insufficient workspace (see *lwork*, *orfac* and *info*). Eigenvectors corresponding to clusters of eigenvalues indexed $iclustr(2*i-1)$ to $iclustr(2*i)$, could not be reorthogonalized due to lack of workspace. Hence the eigenvectors corresponding to these clusters may not be orthogonal.

iclustr() is a zero terminated array. ($iclustr(2*k) \neq 0$ and $iclustr(2*k+1)=0$) if and only if k is the number of clusters.

iclustr is not referenced if $jobz = 'N'$.

gap

(global)

Array of size $NPROW*NPCOL$.

This array contains the gap between eigenvalues whose eigenvectors could not be reorthogonalized. The output values in this array correspond to the clusters indicated by the array *iclustr*. As a result, the dot product between eigenvectors corresponding to the i -th cluster may be as high as $(C*n)/gap(i)$, where C is a small constant.

info

(global)

If $info = 0$, the execution is successful.

If $info < 0$: the i -th argument is an array and the j -entry had an illegal value, then $info = -(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

If $info > 0$:

If $(\text{mod}(info, 2) \neq 0)$, then one or more eigenvectors failed to converge. Their indices are stored in *ifail*.

If $(\text{mod}(info, 2, 2) \neq 0)$, then eigenvectors corresponding to one or more clusters of eigenvalues could not be reorthogonalized because of insufficient workspace. The indices of the clusters are stored in the array *iclustr*.

If $(\text{mod}(info/4, 2) \neq 0)$, then space limit prevented `p?sygvx` from computing all of the eigenvectors between vl and vu . The number of eigenvectors computed is returned in *nz*.

If $(\text{mod}(info/8, 2) \neq 0)$, then `p?stebz` failed to compute eigenvalues.

If $(\text{mod}(info/16, 2) \neq 0)$, then B was not positive definite. *ifail*(1) indicates the order of the smallest minor which is not positive definite.

ScaLAPACK Auxiliary, Utility, and Redistribution/Copy Routines

5

This chapter describes the Intel® Math Kernel Library implementation of ScaLAPACK [Auxiliary Routines](#), [Utility Functions and Routines](#), and [Matrix Redistribution/Copy Routines](#). The library includes routines for both real and complex data.

NOTE

ScaLAPACK routines are provided only for Intel® 64 or Intel® Many Integrated Core architectures.

Routine naming conventions, mathematical notation, and matrix storage schemes used for ScaLAPACK auxiliary and utility routines are the same as described in previous chapters. Some routines and functions may have combined character codes, such as `sc` or `dz`. For example, the routine `pzcsum1` uses a complex input array and returns a real value.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Auxiliary Routines

ScaLAPACK Auxiliary Routines

Routine Name	Data Types	Description
<code>b?laapp</code>	<code>s, d</code>	Multiplies a matrix with an orthogonal matrix.
<code>b?laexc</code>	<code>s, d</code>	Swaps adjacent diagonal blocks of a real upper quasi-triangular matrix in Schur canonical form, by an orthogonal similarity transformation.
<code>b?trexc</code>	<code>s, d</code>	Reorders the Schur factorization of a general matrix.
<code>p?lacgv</code>	<code>c, z</code>	Conjugates a complex vector.
<code>p?max1</code>	<code>c, z</code>	Finds the index of the element whose real part has maximum absolute value (similar to the Level 1 PBLAS <code>p?amax</code> , but using the absolute value to the real part).
<code>pmpcol</code>	<code>s, d</code>	<i>Finds the collaborators of a process.</i>
<code>pmpim2</code>	<code>s, d</code>	Computes the eigenpair range assignments for all processes.

Routine Name	Data Types	Description
?combamax1	c, z	Finds the element with maximum real part absolute value and its corresponding global index.
p?sum1	sc, dz	Forms the 1-norm of a complex vector similar to Level 1 PBLAS p?asum , but using the true absolute value.
p?dbtrsv	s, d, c, z	Computes an <i>LU</i> factorization of a general tridiagonal matrix with no pivoting. The routine is called by p?dbtrs .
p?dttrsv	s, d, c, z	Computes an <i>LU</i> factorization of a general band matrix, using partial pivoting with row interchanges. The routine is called by p?dttrs .
p?gebal	s, d	Balances a general real matrix.
p?gebd2	s, d, c, z	Reduces a general rectangular matrix to real bidiagonal form by an orthogonal/unitary transformation (unblocked algorithm).
p?gehd2	s, d, c, z	Reduces a general matrix to upper Hessenberg form by an orthogonal/unitary similarity transformation (unblocked algorithm).
p?gelq2	s, d, c, z	Computes an <i>LQ</i> factorization of a general rectangular matrix (unblocked algorithm).
p?geql2	s, d, c, z	Computes a <i>QL</i> factorization of a general rectangular matrix (unblocked algorithm).
p?geqr2	s, d, c, z	Computes a <i>QR</i> factorization of a general rectangular matrix (unblocked algorithm).
p?gerq2	s, d, c, z	Computes an <i>RQ</i> factorization of a general rectangular matrix (unblocked algorithm).
p?getf2	s, d, c, z	Computes an <i>LU</i> factorization of a general matrix, using partial pivoting with row interchanges (local blocked algorithm).
p?labrd	s, d, c, z	Reduces the first <i>nb</i> rows and columns of a general rectangular matrix A to real bidiagonal form by an orthogonal/unitary transformation, and returns auxiliary matrices that are needed to apply the transformation to the unreduced part of A.
p?lacon	s, d, c, z	Estimates the 1-norm of a square matrix, using the reverse communication for evaluating matrix-vector products.
p?laconsb	s, d	Looks for two consecutive small subdiagonal elements.
p?lACP2	s, d, c, z	Copies all or part of a distributed matrix to another distributed matrix.
p?lACP3	s, d	Copies from a global parallel array into a local replicated array or vice versa.
p?lACPY	s, d, c, z	Copies all or part of one two-dimensional array to another.
p?laevswp	s, d, c, z	Moves the eigenvectors from where they are computed to ScaLAPACK standard block cyclic array.
p?lahrd	s, d, c, z	Reduces the first <i>nb</i> columns of a general rectangular matrix A so that elements below the k^{th} subdiagonal are zero, by an orthogonal/unitary transformation, and returns auxiliary matrices that are needed to apply the transformation to the unreduced part of A.

Routine Name	Data Types	Description
<code>p?laiect</code>	<code>s, d, c, z</code>	Exploits IEEE arithmetic to accelerate the computations of eigenvalues.
<code>p?lamve</code>	<code>s, d</code>	Copies all or part of one two-dimensional distributed array to another.
<code>p?lange</code>	<code>s, d, c, z</code>	Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of a general rectangular matrix.
<code>p?lanhs</code>	<code>s, d, c, z</code>	Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of an upper Hessenberg matrix.
<code>p?lansy, p?lanhe</code>	<code>s, d, c, z / c, z</code>	Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element of a real symmetric or complex Hermitian matrix.
<code>p?lantr</code>	<code>s, d, c, z</code>	Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of a triangular matrix.
<code>p?lapiv</code>	<code>s, d, c, z</code>	Applies a permutation matrix to a general distributed matrix, resulting in row or column pivoting.
<code>p?laqge</code>	<code>s, d, c, z</code>	Scales a general rectangular matrix, using row and column scaling factors computed by <code>p?geequ</code> .
<code>p?laqr0</code>	<code>s, d</code>	Computes the eigenvalues of a Hessenberg matrix and optionally returns the matrices from the Schur decomposition.
<code>p?laqr1</code>	<code>s, d</code>	Sets a scalar multiple of the first column of the product of a 2-by-2 or 3-by-3 matrix and specified shifts.
<code>p?laqr2</code>	<code>s, d</code>	Performs the orthogonal/unitary similarity transformation of a Hessenberg matrix to detect and deflate fully converged eigenvalues from a trailing principal submatrix (aggressive early deflation).
<code>p?laqr3</code>	<code>s, d</code>	Performs the orthogonal/unitary similarity transformation of a Hessenberg matrix to detect and deflate fully converged eigenvalues from a trailing principal submatrix (aggressive early deflation).
<code>p?laqr4</code>	<code>s, d</code>	Computes the eigenvalues of a Hessenberg matrix, and optionally computes the matrices from the Schur decomposition.
<code>p?laqr5</code>	<code>s, d</code>	Performs a single small-bulge multi-shift QR sweep.
<code>p?laqsy</code>	<code>s, d, c, z</code>	Scales a symmetric/Hermitian matrix, using scaling factors computed by <code>p?poequ</code> .
<code>p?lared1d</code>	<code>s, d</code>	Redistributes an array assuming that the input array <i>bycol</i> is distributed across rows and that all process columns contain the same copy of <i>bycol</i> .
<code>p?lared2d</code>	<code>s, d</code>	Redistributes an array assuming that the input array <i>byrow</i> is distributed across columns and that all process rows contain the same copy of <i>byrow</i> .
<code>p?larf</code>	<code>s, d, c, z</code>	Applies an elementary reflector to a general rectangular matrix.

Routine Name	Data Types	Description
p?larfb	<i>s, d, c, z</i>	Applies a block reflector or its transpose/conjugate-transpose to a general rectangular matrix.
p?larfc	<i>c, z</i>	Applies the conjugate transpose of an elementary reflector to a general matrix.
p?larfg	<i>s, d, c, z</i>	Generates an elementary reflector (Householder matrix).
p?larft	<i>s, d, c, z</i>	Forms the triangular vector T of a block reflector $H=I- VTV^H$
p?larz	<i>s, d, c, z</i>	Applies an elementary reflector as returned by p?tzrzf to a general matrix.
p?larzb	<i>s, d, c, z</i>	Applies a block reflector or its transpose/conjugate-transpose as returned by p?tzrzf to a general matrix.
p?larzc	<i>c, z</i>	Applies (multiplies by) the conjugate transpose of an elementary reflector as returned by p?tzrzf to a general matrix.
p?larzt	<i>s, d, c, z</i>	Forms the triangular factor T of a block reflector $H=I- VTV^H$ as returned by p?tzrzf .
p?lascl	<i>s, d, c, z</i>	Multiplies a general rectangular matrix by a real scalar defined as C_{to}/C_{from} .
p?laset	<i>s, d, c, z</i>	Initializes the off-diagonal elements of a matrix to α and the diagonal elements to β .
p?lasmsub	<i>s, d</i>	Looks for a small subdiagonal element from the bottom of the matrix that it can safely set to zero.
p?lassq	<i>s, d, c, z</i>	Updates a sum of squares represented in scaled form.
p?laswp	<i>s, d, c, z</i>	Performs a series of row interchanges on a general rectangular matrix.
p?latra	<i>s, d, c, z</i>	Computes the trace of a general square distributed matrix.
p?latrd	<i>s, d, c, z</i>	Reduces the first nb rows and columns of a symmetric/Hermitian matrix A to real tridiagonal form by an orthogonal/unitary similarity transformation.
p?latrz	<i>s, d, c, z</i>	Reduces an upper trapezoidal matrix to upper triangular form by means of orthogonal/unitary transformations.
p?lauu2	<i>s, d, c, z</i>	Computes the product UU^H or L^HL , where U and L are upper or lower triangular matrices (local unblocked algorithm).
p?lauum	<i>s, d, c, z</i>	Computes the product UU^H or L^HL , where U and L are upper or lower triangular matrices.
p?lawil	<i>s, d</i>	Forms the Wilkinson transform.
p?org2l/p?ung2l	<i>s, d, c, z</i>	Generates all or part of the orthogonal/unitary matrix Q from a QL factorization determined by p?geqlf (unblocked algorithm).
p?org2r/p?ung2r	<i>s, d, c, z</i>	Generates all or part of the orthogonal/unitary matrix Q from a QR factorization determined by p?geqrf (unblocked algorithm).
p?orgl2/p?ungl2	<i>s, d, c, z</i>	Generates all or part of the orthogonal/unitary matrix Q from an LQ factorization determined by p?gelqf (unblocked algorithm).

Routine Name	Data Types	Description
p?orgqr2/p?ungr2	<i>s, d, c, z</i>	Generates all or part of the orthogonal/unitary matrix Q from an RQ factorization determined by p?gerqf (unblocked algorithm).
p?orm2l/p?unm2l	<i>s, d, c, z</i>	Multiplies a general matrix by the orthogonal/unitary matrix from a QL factorization determined by p?geqlf (unblocked algorithm).
p?orm2r/p?unm2r	<i>s, d, c, z</i>	Multiplies a general matrix by the orthogonal/unitary matrix from a QR factorization determined by p?geqrf (unblocked algorithm).
p?orml2/p?unml2	<i>s, d, c, z</i>	Multiplies a general matrix by the orthogonal/unitary matrix from an LQ factorization determined by p?gelqf (unblocked algorithm).
p?ormr2/p?unmr2	<i>s, d, c, z</i>	Multiplies a general matrix by the orthogonal/unitary matrix from an RQ factorization determined by p?gerqf (unblocked algorithm).
p?pbtrsv	<i>s, d, c, z</i>	Solves a single triangular linear system via frontsolve or backsolve where the triangular matrix is a factor of a banded matrix computed by p?pbtrf .
p?pttrsv	<i>s, d, c, z</i>	Solves a single triangular linear system via frontsolve or backsolve where the triangular matrix is a factor of a tridiagonal matrix computed by p?pttrf .
p?potf2	<i>s, d, c, z</i>	Computes the Cholesky factorization of a symmetric/Hermitian positive definite matrix (local unblocked algorithm).
p?rot	<i>s, d</i>	Applies a planar rotation to two distributed vectors.
p?rscl	<i>s, d, cs, zd</i>	Multiplies a vector by the reciprocal of a real scalar.
p?sygs2/p?hegs2	<i>s, d, c, z</i>	Reduces a symmetric/Hermitian positive-definite generalized eigenproblem to standard form, using the factorization results obtained from p?potrf (local unblocked algorithm).
p?sytd2/p?hetd2	<i>s, d, c, z</i>	Reduces a symmetric/Hermitian matrix to real symmetric tridiagonal form by an orthogonal/unitary similarity transformation (local unblocked algorithm).
p?trord	<i>s, d</i>	Reorders the Schur factorization of a general matrix.
p?trsen	<i>s, d</i>	Reorders the Schur factorization of a matrix and (optionally) computes the reciprocal condition numbers and invariant subspace for the selected cluster of eigenvalues.
p?trti2	<i>s, d, c, z</i>	Computes the inverse of a triangular matrix (local unblocked algorithm).
?lamsh	<i>s, d</i>	Sends multiple shifts through a small (single node) matrix to maximize the number of bulges that can be sent through.
?laqr6	<i>s, d</i>	Performs a single small-bulge multi-shift QR sweep collecting the transformations.
?lar1va	<i>s, d</i>	<i>Computes scaled eigenvector corresponding to given eigenvalue.</i>
?laref	<i>s, d</i>	Applies Householder reflectors to matrices on either their rows or columns.
?larrb2	<i>s, d</i>	Provides limited bisection to locate eigenvalues for more accuracy.
?larrrd2	<i>s, d</i>	Computes the eigenvalues of a symmetric tridiagonal matrix to suitable accuracy.

Routine Name	Data Types	Description
?larre2	s, d	Given a tridiagonal matrix, sets small off-diagonal elements to zero and for each unreduced block, finds base representations and eigenvalues.
?larre2a	s, d	<i>Given a tridiagonal matrix, sets small off-diagonal elements to zero and for each unreduced block, finds base representations and eigenvalues.</i>
?larrf2	s, d	Finds a new relatively robust representation such that at least one of the eigenvalues is relatively isolated.
?larrv2	s, d	Computes the eigenvectors of the tridiagonal matrix $T = L * D * L^T$ given L , D and the eigenvalues of $L * D * L^T$.
?lasorte	s, d	Sorts eigenpairs by real and complex data types.
?lasrt2	s, d	Sorts numbers in increasing or decreasing order.
?stegr2	s, d	Computes selected eigenvalues and eigenvectors of a real symmetric tridiagonal matrix.
?stegr2a	s, d	Computes selected eigenvalues and initial representations needed for eigenvector computations.
?stegr2b	s, d	From eigenvalues and initial representations computes the selected eigenvalues and eigenvectors of the real symmetric tridiagonal matrix in parallel on multiple processors.
?stein2	s, d	Computes the eigenvectors corresponding to specified eigenvalues of a real symmetric tridiagonal matrix, using inverse iteration.
?dbtf2	s, d, c, z	Computes an LU factorization of a general band matrix with no pivoting (local unblocked algorithm).
?dbtrf	s, d, c, z	Computes an LU factorization of a general band matrix with no pivoting (local blocked algorithm).
?dttrf	s, d, c, z	Computes an LU factorization of a general tridiagonal matrix with no pivoting (local blocked algorithm).
?dttrsv	s, d, c, z	Solves a general tridiagonal system of linear equations using the LU factorization computed by ?dttrf .
?pttrsv	s, d, c, z	Solves a symmetric (Hermitian) positive-definite tridiagonal system of linear equations, using the LDL^H factorization computed by ?pttrf .
?steqr2	s, d	Computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method.

Notice revision #20110804

p?lacgv*Conjugates a complex vector.***Syntax**

```
void pclacgv (MKL_INT *n , MKL_Complex8 *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx );

void pzlacgv (MKL_INT *n , MKL_Complex16 *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx );
```

Include Files

- mkl_scalapack.h

Description

The p?lacgv function conjugates a complex vector $\text{sub}(X)$ of length n , where $\text{sub}(X)$ denotes $X(ix, jx:jx+n-1)$ if $incx = m_x$, and $X(ix:ix+n-1, jx)$ if $incx = 1$.

Input Parameters

n	(global) The length of the distributed vector $\text{sub}(X)$.
x	(local). Pointer into the local memory to an array of size $lld_x * LOCC(n_x)$. On entry the vector to be conjugated $x[i] = X(ix+(jx-1)*m_x+i*incx)$, $0 \leq i < n$.
ix	(global) The row index in the global matrix X indicating the first row of $\text{sub}(X)$.
jx	(global) The column index in the global matrix X indicating the first column of $\text{sub}(X)$.
$descx$	(global and local) Array of size $dlen_=9$. The array descriptor for the distributed matrix X .
$incx$	(global) The global increment for the elements of X . Only two values of $incx$ are supported in this version, namely 1 and m_x . $incx$ must not be zero.

Output Parameters

x	(local). On exit, the local pieces of conjugated distributed vector $\text{sub}(X)$.

See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

p?max1

Finds the index of the element whose real part has maximum absolute value (similar to the Level 1 PBLAS p?amax, but using the absolute value to the real part).

Syntax

```
void p?cmax1 (MKL_INT *n , MKL_Complex8 *amax , MKL_INT *indx , MKL_Complex8 *x ,
MKL_INT *ix , MKL_INT *jx , MKL_INT *descx , MKL_INT *incx );

void p?zmax1 (MKL_INT *n , MKL_Complex16 *amax , MKL_INT *indx , MKL_Complex16 *x ,
MKL_INT *ix , MKL_INT *jx , MKL_INT *descx , MKL_INT *incx );
```

Include Files

- mkl_scalapack.h

Description

The `p?max1` function computes the global index of the maximum element in absolute value of a distributed vector `sub(X)`. The global index is returned in `indx` and the value is returned in `amax`, where `sub(X)` denotes `X(ix:ix+n-1, jx)` if `incx = 1`, `X(ix, jx:jx+n-1)` if `incx = m_x`.

Input Parameters

<code>n</code>	(global). The number of components of the distributed vector <code>sub(X)</code> . $n \geq 0$.
<code>x</code>	(local) Pointer into the local memory to an array of size <code>lld_x * LOCc(jx+n-1)</code> . On entry this array contains the local pieces of the distributed vector <code>sub(X)</code> .
<code>ix</code>	(global) The row index in the global matrix <code>X</code> indicating the first row of <code>sub(X)</code> .
<code>jx</code>	(global) The column index in the global matrix <code>X</code> indicating the first column of <code>sub(X)</code> .
<code>descx</code>	(global and local) Array of size <code>dlen_</code> . The array descriptor for the distributed matrix <code>X</code> .
<code>incx</code>	(global). The global increment for the elements of <code>X</code> . Only two values of <code>incx</code> are supported in this version, namely 1 and <code>m_x</code> . <code>incx</code> must not be zero.

Output Parameters

<code>amax</code>	(global output). The absolute value of the largest entry of the distributed vector <code>sub(X)</code> only in the scope of <code>sub(X)</code> .
<code>indx</code>	(global output). The global index of the element of the distributed vector <code>sub(X)</code> whose real part has maximum absolute value.

See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

pmpcol

Finds the collaborators of a process.

Syntax

```
void pmpcol(MKL_INT* myproc, MKL_INT* nprocs, MKL_INT* iil, MKL_INT* needil, MKL_INT*
neediu, MKL_INT* pmyils, MKL_INT* pmyius, MKL_INT* colbrt, MKL_INT* frstcl, MKL_INT*
lastcl);
```

Include Files

- `mkl_scalapack.h`

Description

Using the output from `pmpim2` and given the information on eigenvalue clusters, `pmpcol` finds the collaborators of `myproc`.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Notice revision #20110804

Input Parameters

<code>myproc</code>	The processor number, $0 \leq myproc < nprocs$.
<code>nprocs</code>	The total number of processors available.
<code>iil</code>	The index of the leftmost eigenvalue in the eigenvalue cluster.
<code>needil</code>	The leftmost position in the eigenvalue cluster needed by <code>myproc</code> .
<code>neediu</code>	The rightmost position in the eigenvalue cluster needed by <code>myproc</code> .
<code>pmyils</code>	array For each processor p , $0 < p \leq nprocs$, <code>pmyils[p-1]</code> is the index of the first eigenvalue in the eigenvalue cluster to be computed. <code>pmyils[p-1]</code> equals zero if p stays idle.
<code>pmyius</code>	array For each processor p , <code>pmyius[p-1]</code> is the index of the last eigenvalue in the eigenvalue cluster to be computed. <code>pmyius[p-1]</code> equals zero if p stays idle.

OUTPUT Parameters

<code>colbrt</code>	Non-zero if <code>myproc</code> collaborates.
<code>frstcl, lastcl</code>	First and last collaborator of <code>myproc</code> . <code>myproc</code> collaborates with: <code>frstcl, ..., myproc-1, myproc+1, ..., lastcl</code> If <code>myproc = frstcl</code> , there are no collaborators on the left. If <code>myproc = lastcl</code> , there are no collaborators on the right.

If *firstcl* = 0 and *lastcl* = *nprocs*-1, then *myproc* collaborates with everybody

pmpim2

Computes the eigenpair range assignments for all processes.

Syntax

```
void pmpim2(MKL_INT* il, MKL_INT* iu, MKL_INT* nprocs, MKL_INT* pmyils, MKL_INT*
pmyius);
```

Include Files

- mkl_scalapack.h

Description

pmpim2 is the scheduling function. It computes for all processors the eigenpair range assignments.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

il, iu The range of eigenpairs to be computed.

nprocs The total number of processors available.

Output Parameters

pmyils array
For each processor *p*, *pmyils*[*p*-1] is the index of the first eigenvalue in a cluster to be computed.
pmyils[*p*-1] equals zero if *p* stays idle.

pmyius array
For each processor *p*, *pmyius*[*p*-1] is the index of the last eigenvalue in a cluster to be computed.
pmyius[*p*-1] equals zero if *p* stays idle.

?combamax1

Finds the element with maximum real part absolute value and its corresponding global index.

Syntax

```
void ccombamax1 (MKL_Complex8 *v1 , MKL_Complex8 *v2 );
void zcombamax1 (MKL_Complex16 *v1 , MKL_Complex16 *v2 );
```

Include Files

- mkl_scalapack.h

Description

The ?combamax1 function finds the element having maximum real part absolute value as well as its corresponding global index.

Input Parameters

<i>v1</i>	(local) Array of size 2. The first maximum absolute value element and its global index. <i>v1</i> [0]=amax, <i>v1</i> [1]=indx.
<i>v2</i>	(local) Array of size 2. The second maximum absolute value element and its global index. <i>v2</i> [0]=amax, <i>v2</i> [1]=indx.

Output Parameters

<i>v1</i>	(local). The first maximum absolute value element and its global index. <i>v1</i> [0]=amax, <i>v1</i> [1]=indx.

See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

p?sum1

Forms the 1-norm of a complex vector similar to Level 1 PBLAS p?asum, but using the true absolute value.

Syntax

```
void pscsum1 (MKL_INT *n , float *asum , MKL_Complex8 *x , MKL_INT *ix , MKL_INT *jx ,
MKL_INT *descx , MKL_INT *incx );
void pdzsum1 (MKL_INT *n , double *asum , MKL_Complex16 *x , MKL_INT *ix , MKL_INT
*jx , MKL_INT *descx , MKL_INT *incx );
```

Include Files

- mkl_scalapack.h

Description

The `p?sum1` function returns the sum of absolute values of a complex distributed vector `sub(x)` in `asum`, where `sub(x)` denotes $X(ix:ix+n-1, jx:jx)$, if `incx = 1`, $X(ix:ix, jx:jx+n-1)$, if `incx = m_x`.

Based on `p?asum` from the Level 1 PBLAS. The change is to use the 'genuine' absolute value.

Input Parameters

<code>n</code>	(global). The number of components of the distributed vector <code>sub(x)</code> . $n \geq 0$.
<code>x</code>	(local) Pointer into the local memory to an array of size <code>lld_x * LOCc(jx+n-1)</code> . This array contains the local pieces of the distributed vector <code>sub(X)</code> .
<code>ix</code>	(global) The row index in the global matrix <code>X</code> indicating the first row of <code>sub(X)</code> .
<code>jx</code>	(global) The column index in the global matrix <code>X</code> indicating the first column of <code>sub(X)</code>
<code>descx</code>	(local) Array of size <code>dlen_ = 9</code> . The array descriptor for the distributed matrix <code>X</code> .
<code>incx</code>	(global) The global increment for the elements of <code>X</code> . Only two values of <code>incx</code> are supported in this version, namely 1 and <code>m_x</code> .

Output Parameters

<code>asum</code>	(local) The sum of absolute values of the distributed vector <code>sub(X)</code> only in its scope.

p?dbtrsv

Computes an LU factorization of a general triangular matrix with no pivoting. The function is called by `p?dbtrsv`.

Syntax

```
void psdbtrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *bwl , MKL_INT *bwu ,
MKL_INT *nrhs , float *a , MKL_INT *ja , MKL_INT *desca , float *b , MKL_INT *ib ,
MKL_INT *descb , float *af , MKL_INT *laf , float *work , MKL_INT *lwork , MKL_INT
*info );

void pddbtrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *bwl , MKL_INT *bwu ,
MKL_INT *nrhs , double *a , MKL_INT *ja , MKL_INT *desca , double *b , MKL_INT *ib ,
MKL_INT *descb , double *af , MKL_INT *laf , double *work , MKL_INT *lwork , MKL_INT
*info );

void pcdbtrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *bwl , MKL_INT *bwu ,
MKL_INT *nrhs , MKL_Complex8 *a , MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *b ,
MKL_INT *ib , MKL_INT *descb , MKL_Complex8 *af , MKL_INT *laf , MKL_Complex8 *work ,
MKL_INT *lwork , MKL_INT *info );
```

```
void pzdbtrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *bwl , MKL_INT *bwu ,
MKL_INT *nrhs , MKL_Complex16 *a , MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *b ,
MKL_INT *ib , MKL_INT *descb , MKL_Complex16 *af , MKL_INT *laf , MKL_Complex16
*work , MKL_INT *lwork , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The pzdbtrsv function solves a banded triangular system of linear equations

$A(1:n, ja:ja+n-1) * X = B(ib:ib+n-1, 1:nrhs)$ or

$A(1:n, ja:ja+n-1)^T * X = B(ib:ib+n-1, 1:nrhs)$ (for real flavors); $A(1:n, ja:ja+n-1)^H * X = B(ib:ib+n-1, 1:nrhs)$ (for complex flavors),

where $A(1:n, ja:ja+n-1)$ is a banded triangular matrix factor produced by the Gaussian elimination code of pzdbtrf and is stored in $A(1:n, ja:ja+n-1)$ and af . The matrix stored in $A(1:n, ja:ja+n-1)$ is either upper or lower triangular according to *uplo*, and the choice of solving $A(1:n, ja:ja+n-1)$ or $A(1:n, ja:ja+n-1)^T$ is dictated by the user by the parameter *trans*.

The function pzdbtrf must be called first.

Input Parameters

<i>uplo</i>	(global) If <i>uplo</i> = 'U', the upper triangle of $A(1:n, ja:ja+n-1)$ is stored, if <i>uplo</i> = 'L', the lower triangle of $A(1:n, ja:ja+n-1)$ is stored.
<i>trans</i>	(global) If <i>trans</i> = 'N', solve with $A(1:n, ja:ja+n-1)$, if <i>trans</i> = 'C', solve with conjugate transpose $A(1:n, ja:ja+n-1)$.
<i>n</i>	(global) The order of the distributed submatrix A ; ($n \geq 0$).
<i>bwl</i>	(global) Number of subdiagonals. $0 \leq bwl \leq n-1$.
<i>bwu</i>	(global) Number of subdiagonals. $0 \leq bwu \leq n-1$.
<i>nrhs</i>	(global) The number of right-hand sides; the number of columns of the distributed submatrix B ($nrhs \geq 0$).
<i>a</i>	(local). Pointer into the local memory to an array of size $lld\_a * LOCC(ja+n-1)$, where $lld\_a \geq (bwl+bwu+1)$. On entry, this array contains the local pieces of the n -by- n unsymmetric banded distributed Cholesky factor L or L^T , represented in global A as $A(1:n, ja:ja+n-1)$. This local portion is stored in the packed banded format used in LAPACK. See the <i>Application Notes</i> below and the ScaLAPACK manual for more detail on the format of distributed matrices.
<i>ja</i>	(global) The index in the global matrix A that points to the start of the matrix to be operated on (which may be either all of A or a submatrix of A).
<i>desca</i>	(global and local) array of size <i>dlen_</i> .

	if 1d type ($dtype\_a = 501$ or 502), $dlen \geq 7$; if 2d type ($dtype\_a = 1$), $dlen \geq 9$. The array descriptor for the distributed matrix A. Contains information of mapping of A to memory.
<i>b</i>	(local) Pointer into the local memory to an array of local lead dimension $lld\_b \geq nb$. On entry, this array contains the local pieces of the right-hand sides $B(ib:ib+n-1, 1:nrhs)$.
<i>ib</i>	(global) The row index in the global matrix B that points to the first row of the matrix to be operated on (which may be either all of B or a submatrix of B).
<i>descb</i>	(global and local) array of size $dlen\_$. if 1d type ($dtype\_b = 502$), $dlen \geq 7$; if 2d type ($dtype\_b = 1$), $dlen \geq 9$. The array descriptor for the distributed matrix B. Contains information of mapping B to memory.
<i>laf</i>	(local) Size of user-input auxiliary fill-in space af. $laf \geq nb * (bwl + bwu) + 6 * \max(bwl, bwu) * \max(bwl, bwu)$. If laf is not large enough, an error code is returned and the minimum acceptable size will be returned in $af[0]$.
<i>work</i>	(local). Temporary workspace. This space may be overwritten in between function calls. <i>work</i> must be the size given in <i>lwork</i>.
<i>lwork</i>	(local or global) Size of user-input workspace <i>work</i>. If <i>lwork</i> is too small, the minimal acceptable size will be returned in <i>work[0]</i> and an error code is returned. $lwork \geq \max(bwl, bwu) * nrhs$.

Output Parameters

<i>a</i>	(local). This local portion is stored in the packed banded format used in LAPACK. Please see the ScaLAPACK manual for more detail on the format of distributed matrices.
<i>b</i>	On exit, this contains the local piece of the solutions distributed matrix X.
<i>af</i>	(local). auxiliary fill-in space. The fill-in space is created in a call to the factorization function <code>p?dbtrf</code> and is stored in <i>af</i>. If a linear system is to be solved using <code>p?dbtrf</code> after the factorization function, <i>af</i> must not be altered after the factorization.

work On exit, *work*[0] contains the minimal *lwork*.

info (local).
 If *info* = 0, the execution is successful.
 < 0: If the *i*-th argument is an array and the *j*-th entry, indexed *j*-1, had an illegal value, then *info* = - (i*100+j), if the *i*-th argument is a scalar and had an illegal value, then *info* = -i.

p?dttrsv

Computes an LU factorization of a general band matrix, using partial pivoting with row interchanges. The function is called by p?dttrs.

Syntax

```
void psdttrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *nrhs , float *dl ,
float *d , float *du , MKL_INT *ja , MKL_INT *desca , float *b , MKL_INT *ib , MKL_INT
*descb , float *af , MKL_INT *laf , float *work , MKL_INT *lwork , MKL_INT *info );

void pddttrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *nrhs , double *dl ,
double *d , double *du , MKL_INT *ja , MKL_INT *desca , double *b , MKL_INT *ib ,
MKL_INT *descb , double *af , MKL_INT *laf , double *work , MKL_INT *lwork , MKL_INT
*info );

void pcdttrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *nrhs , MKL_Complex8
*d , MKL_Complex8 *d , MKL_Complex8 *du , MKL_INT *ja , MKL_INT *desca , MKL_Complex8
*b , MKL_INT *ib , MKL_INT *descb , MKL_Complex8 *af , MKL_INT *laf , MKL_Complex8
*work , MKL_INT *lwork , MKL_INT *info );

void pzdttrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *nrhs , MKL_Complex16
*d , MKL_Complex16 *d , MKL_Complex16 *du , MKL_INT *ja , MKL_INT *desca ,
MKL_Complex16 *b , MKL_INT *ib , MKL_INT *descb , MKL_Complex16 *af , MKL_INT *laf ,
MKL_Complex16 *work , MKL_INT *lwork , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The p?dttrsv function solves a tridiagonal triangular system of linear equations

$$A(1:n, ja:ja+n-1) * X = B(ib:ib+n-1, 1:nrhs) \text{ or}$$

$$A(1:n, ja:ja+n-1)^T * X = B(ib:ib+n-1, 1:nrhs) \text{ for real flavors; } A(1:n, ja:ja+n-1)^H * X = B(ib:ib+n-1, 1:nrhs) \text{ for complex flavors,}$$

where $A(1:n, ja:ja+n-1)$ is a tridiagonal matrix factor produced by the Gaussian elimination code of p?dttrf and is stored in $A(1:n, ja:ja+n-1)$ and *af*.

The matrix stored in $A(1:n, ja:ja+n-1)$ is either upper or lower triangular according to *uplo*, and the choice of solving $A(1:n, ja:ja+n-1)$ or $A(1:n, ja:ja+n-1)^T$ is dictated by the user by the parameter *trans*.

The function p?dttrf must be called first.

Input Parameters

<i>uplo</i>	(global) If <i>uplo</i>='U', the upper triangle of $A(1:n, ja:ja+n-1)$ is stored, if <i>uplo</i> = 'L', the lower triangle of $A(1:n, ja:ja+n-1)$ is stored.
<i>trans</i>	(global) If <i>trans</i> = 'N', solve with $A(1:n, ja:ja+n-1)$, if <i>trans</i> = 'C', solve with conjugate transpose $A(1:n, ja:ja+n-1)$.
<i>n</i>	(global) The order of the distributed submatrix A ; ($n \geq 0$).
<i>nrhs</i>	(global) The number of right-hand sides; the number of columns of the distributed submatrix $B(ib:ib+n-1, 1:nrhs)$. ($nrhs \geq 0$).
<i>d1</i>	(local). Pointer to local part of global vector storing the lower diagonal of the matrix. Globally, <i>d1</i>[0] is not referenced, and <i>d1</i> must be aligned with <i>d</i>. Must be of size $\geq nb\_a$.
<i>d</i>	(local). Pointer to local part of global vector storing the main diagonal of the matrix.
<i>du</i>	(local). Pointer to local part of global vector storing the upper diagonal of the matrix. Globally, <i>du</i>[<i>n</i>-1] is not referenced, and <i>du</i> must be aligned with <i>d</i>.
<i>ja</i>	(global) The index in the global matrix A that points to the start of the matrix to be operated on (which may be either all of A or a submatrix of A).
<i>desca</i>	(global and local) array of size <i>dlen_</i>. if 1<i>d</i> type (<i>dtype_a</i> = 501 or 502), <i>dlen</i> ≥ 7; if 2<i>d</i> type (<i>dtype_a</i> = 1), <i>dlen</i> ≥ 9. The array descriptor for the distributed matrix A. Contains information of mapping of A to memory.
<i>b</i>	(local) Pointer into the local memory to an array of local lead dimension $lld\_b \geq nb$. On entry, this array contains the local pieces of the right-hand sides $B(ib:ib+n-1, 1:nrhs)$.
<i>ib</i>	(global) The row index in the global matrix B that points to the first row of the matrix to be operated on (which may be either all of B or a submatrix of B).
<i>descb</i>	(global and local) array of size <i>dlen_</i>. if 1<i>d</i> type (<i>dtype_b</i> = 502), <i>dlen</i> ≥ 7;

if 2d type ($dtype\_b = 1$), $dlen \geq 9$.

The array descriptor for the distributed matrix B . Contains information of mapping B to memory.

laf

(local).

Size of user-input auxiliary fill-in space *af*.

$laf \geq 2*(nb+2)$. If *laf* is not large enough, an error code is returned and the minimum acceptable size will be returned in *af*[0].

work

(local).

Temporary workspace. This space may be overwritten in between function calls.

work must be the size given in *lwork*.

lwork

(local or global)

Size of user-input workspace *work*. If *lwork* is too small, the minimal acceptable size will be returned in *work*[0] and an error code is returned.

$lwork \geq 10*npcol+4*nrhs$.

Output Parameters

dl

(local).

On exit, this array contains information containing the factors of the matrix.

d

On exit, this array contains information containing the factors of the matrix. Must be of size $\geq nb\_a$.

b

On exit, this contains the local piece of the solutions distributed matrix X.

af

(local).

Auxiliary fill-in space. The fill-in space is created in a call to the factorization function `p?dttrf` and is stored in *af*. If a linear system is to be solved using `p?dttrs` after the factorization function, *af* must not be altered after the factorization.

work

On exit, *work*[0] contains the minimal *lwork*.

info

(local).

If *info*=0, the execution is successful.

if *info*< 0: If the *i*-th argument is an array and the *j*-th entry, indexed *j*-1, had an illegal value, then *info* = - (*i**100+*j*), if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

p?gebal

Balances a general real matrix.

Syntax

```
void psgebal(char* job, MKL_INT* n, float* a, MKL_INT* desca, MKL_INT* ilo, MKL_INT*
ihi, float* scale, MKL_INT* info);
```

```
void pdgebal(char* job, MKL_INT* n, double* a, MKL_INT* desca, MKL_INT* ilo, MKL_INT*
ihi, double* scale, MKL_INT* info);
```

Include Files

- mkl_scalapack.h

Description

`p?gebal` balances a general real matrix A . This involves, first, permuting A by a similarity transformation to isolate eigenvalues in the first 1 to $ilo-1$ and last $ihi+1$ to n elements on the diagonal; and second, applying a diagonal similarity transformation to rows and columns ilo to ihi to make the rows and columns as close in norm as possible. Both steps are optional.

Balancing may reduce the 1-norm of the matrix, and improve the accuracy of the computed eigenvalues and/or eigenvectors.

Input Parameters

<i>job</i>	(global) Specifies the operations to be performed on <i>a</i> : = 'N': none: simply set $ilo = 1$, $ihi = n$, $scale[i] = 1.0$ for $i = 0, \dots, n-1$; = 'P': permute only; = 'S': scale only; = 'B': both permute and scale.
<i>n</i>	(global) The order of the matrix A ($n \geq 0$).
<i>a</i>	(local) Pointer into the local memory to an array of size $lld_a * LOC_c(n)$ This array contains the local pieces of global input matrix A .
<i>desca</i>	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix A .

OUTPUT Parameters

<i>a</i>	On exit, <i>a</i> is overwritten by the balanced matrix A . If $job = 'N'$, <i>a</i> is not referenced. See Notes for further details.
<i>ilo, ihi</i>	(global) <i>ilo</i> and <i>ihi</i> are set to integers such that on exit matrix elements $A(i,j)$ are zero if $i > j$ and $j = 1, \dots, ilo-1$ or $i =ihi+1, \dots, n$. If $job = 'N'$ or 'S', $ilo = 1$ and $ihi = n$.
<i>scale</i>	(global) array of size n .

Details of the permutations and scaling factors applied to a . If pj is the index of the row and column interchanged with row and column j and dj is the scaling factor applied to row and column j , then

$scale[j-1] = pj$ for $j = 1, \dots, ilo-1$

$scale[j-1] = dj$ for $j = ilo, \dots, ihi$

The order in which the interchanges are made is n to $ihi+1$, then 1 to $ilo-1$.

info

(global)

= 0: successful exit.

< 0: if *info* = $-i$, the i -th argument had an illegal value.

Application Notes

The permutations consist of row and column interchanges which put the matrix in the form

$$PAP = \begin{pmatrix} T_1 & X & Y \\ 0 & B & Z \\ 0 & 0 & T_2 \end{pmatrix}$$

where T_1 and T_2 are upper triangular matrices whose eigenvalues lie along the diagonal. The column indices ilo and ihi mark the starting and ending columns of the submatrix B . Balancing consists of applying a diagonal similarity transformation $D^{-1}BD$ to make the 1-norms of each row of B and its corresponding column nearly equal. The output matrix is

$$\begin{pmatrix} T_1 & XD & Y \\ 0 & D^{-1}BD & D^{-1}Z \\ 0 & 0 & T_2 \end{pmatrix}$$

Information about the permutations P and the diagonal matrix D is returned in the vector *scale*.

See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

p?gebd2

Reduces a general rectangular matrix to real bidiagonal form by an orthogonal/unitary transformation (unblocked algorithm).

Syntax

```
void psgebd2 (MKL_INT *m , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , float *d , float *e , float *tauq , float *taup , float *work , MKL_INT
*lwork , MKL_INT *info );
```

```
void pdgebd2 (MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *d , double *e , double *tauq , double *taup , double *work ,
MKL_INT *lwork , MKL_INT *info );

void pcgebd2 (MKL_INT *m , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , float *d , float *e , MKL_Complex8 *tauq , MKL_Complex8 *taup ,
MKL_Complex8 *work , MKL_INT *lwork , MKL_INT *info );

void pzgebd2 (MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *d , double *e , MKL_Complex16 *tauq , MKL_Complex16 *taup ,
MKL_Complex16 *work , MKL_INT *lwork , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The `p?gebd2` function reduces a real/complex general m -by- n distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$ to upper or lower bidiagonal form B by an orthogonal/unitary transformation:

$$Q' \cdot \text{sub}(A) \cdot P = B.$$

If $m \geq n$, B is the upper bidiagonal; if $m < n$, B is the lower bidiagonal.

Input Parameters

m	(global) The number of rows of the distributed matrix $\text{sub}(A)$. ($m \geq 0$).
n	(global) The number of columns in the distributed matrix $\text{sub}(A)$. ($n \geq 0$).
a	(local). Pointer into the local memory to an array of size $lld\_a * LOC_c(ja+n-1)$. On entry, this array contains the local pieces of the general distributed matrix $\text{sub}(A)$.
ia, ja	(global) The row and column indices in the global matrix A indicating the first row and the first column of the matrix $\text{sub}(A)$, respectively.
$desca$	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix A .
$work$	(local). This is a workspace array of size $lwork$.
$lwork$	(local or global) The size of the array $work$. $lwork$ is local input and must be at least $lwork \geq \max(mpa0, nqa0)$, where $nb = mb\_a = nb\_a$, $irow = \text{indxg2p}(ia, nb, myrow, rsrc\_a, nprow)$, $iacol = \text{indxg2p}(ja, nb, mycol, csrc\_a, npcot)$, $mpa0 = \text{numroc}(m+irow, nb, myrow, irow, nprow)$,

`nqa0 = numroc(n+icoffa, nb, mycol, iacol, npc0l).`

`indxg2p` and `numroc` are ScaLAPACK tool functions; `myrow`, `mycol`, `nprow`, and `npcol` can be determined by calling the function `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

<code>a</code>	(local). On exit, if $m \geq n$, the diagonal and the first superdiagonal of <code>sub(A)</code> are overwritten with the upper bidiagonal matrix <code>B</code> ; the elements below the diagonal, with the array <code>tauq</code> , represent the orthogonal/unitary matrix <code>Q</code> as a product of elementary reflectors, and the elements above the first superdiagonal, with the array <code>taup</code> , represent the orthogonal matrix <code>P</code> as a product of elementary reflectors. If $m < n$, the diagonal and the first subdiagonal are overwritten with the lower bidiagonal matrix <code>B</code> ; the elements below the first subdiagonal, with the array <code>tauq</code> , represent the orthogonal/unitary matrix <code>Q</code> as a product of elementary reflectors, and the elements above the diagonal, with the array <code>taup</code> , represent the orthogonal matrix <code>P</code> as a product of elementary reflectors. See <i>Applications Notes</i> below.
<code>d</code>	(local) Array of size <code>LOCc(ja+min(m,n)-1)</code> if $m \geq n$; <code>LOCr(ia+min(m,n)-1)</code> otherwise. The distributed diagonal elements of the bidiagonal matrix <code>B</code> : $d[i] = A(i+1,i+1)$, $i=0, 1, \dots, \text{size}(d) - 1$. <code>d</code> is tied to the distributed matrix <code>A</code> .
<code>e</code>	(local) Array of size <code>LOCc(ja+min(m,n)-1)</code> if $m \geq n$; <code>LOCr(ia+min(m,n)-2)</code> otherwise. The distributed diagonal elements of the bidiagonal matrix <code>B</code> : if $m \geq n$, $e[i] = A(i+1,i+2)$ for $i = 0, 1, \dots, n-2$; if $m < n$, $e[i] = A(i+2,i+1)$ for $i = 0, 1, \dots, m-2$. <code>e</code> is tied to the distributed matrix <code>A</code> .
<code>tauq</code>	(local). Array of size <code>LOCc(ja+min(m,n)-1)</code> . The scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix <code>Q</code> . <code>tauq</code> is tied to the distributed matrix <code>A</code> .
<code>taup</code>	(local). Array of size <code>LOCr(ia+min(m,n)-1)</code> . The scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix <code>P</code> . <code>taup</code> is tied to the distributed matrix <code>A</code> .
<code>work</code>	On exit, <code>work[0]</code> returns the minimal and optimal <code>lwork</code> .
<code>info</code>	(local)

If $info = 0$, the execution is successful.

if $info < 0$: If the i -th argument is an array and the j -th entry, indexed $j-1$, had an illegal value, then $info = -(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

Application Notes

The matrices Q and P are represented as products of elementary reflectors:

If $m \geq n$,

$$Q = H(1) * H(2) * \dots * H(n), \text{ and } P = G(1) * G(2) * \dots * G(n-1)$$

Each $H(i)$ and $G(i)$ has the form:

$$H(i) = I - \tau u v^*, \text{ and } G(i) = I - \tau u u^*,$$

where τu and τu are real/complex scalars, and v and u are real/complex vectors. $v(1:i-1) = 0$, $v(i) = 1$, and $v(i+1:m)$ is stored on exit in

$A(ia+i-ia+m-1, ja+i-1)$;

$u(1:i) = 0$, $u(i+1) = 1$, and $u(i+2:n)$ is stored on exit in $A(ia+i-1, ja+i+1:ja+n-1)$;

τu is stored in $\tau u[ja+i-2]$ and τu in $\tau u[ia+i-2]$.

If $m < n$,

$v(1:i) = 0$, $v(i+1) = 1$, and $v(i+2:m)$ is stored on exit in $A(ia+i+1:ia+m-1, ja+i-1)$;

$u(1:i-1) = 0$, $u(i) = 1$, and $u(i+1:n)$ is stored on exit in $A(ia+i-1, ja+i:ja+n-1)$;

τu is stored in $\tau u[ja+i-2]$ and τu in $\tau u[ia+i-2]$.

The contents of $sub(A)$ on exit are illustrated by the following examples:

$m = 6 \text{ and } n = 5 (m > n)$:

$$\begin{bmatrix} d & e & u1 & u1 & u1 \\ v1 & d & e & u2 & u2 \\ v1 & v2 & d & e & u3 \\ v1 & v2 & v3 & d & e \\ v1 & v2 & v3 & v4 & d \\ v1 & v2 & v3 & v4 & v5 \end{bmatrix}$$

$m = 5 \text{ and } n = 6 (m < n)$:

$$\begin{bmatrix} d & v1 & v1 & v1 & v1 & v1 \\ e & d & u2 & u2 & u2 & u2 \\ v1 & e & d & u3 & u3 & u3 \\ v1 & v2 & e & d & u4 & u4 \\ v1 & v2 & v3 & e & d & u5 \end{bmatrix}$$

where d and e denote diagonal and off-diagonal elements of B , vi denotes an element of the vector defining $H(i)$, and ui an element of the vector defining $G(i)$.

MKL_INT *lwork , MKL_INT *info );

```

Include Files

- mkl_scalapack.h

Description

The `p?gehd2` function reduces a real/complex general distributed matrix $\text{sub}(A)$ to upper Hessenberg form H by an orthogonal/unitary similarity transformation: $Q'^* \text{sub}(A) Q = H$, where $\text{sub}(A) = A(ia+n-1 : ia+n-1, ja+n-1 : ja+n-1)$.

Input Parameters

<code>n</code>	(global) The order of the distributed submatrix A . ($n \geq 0$).
<code>ilo, ihi</code>	(global) It is assumed that the matrix $\text{sub}(A)$ is already upper triangular in rows $ia:ia+ilo-2$ and $ia+ihi:ia+n-1$ and columns $ja:ja+jlo-2$ and $ja+jhi:ja+n-1$. See <i>Application Notes</i> for further information. If $n \geq 0$, $1 \leq ilo \leq ihi \leq n$; otherwise set $ilo = 1$, $ihi = n$.
<code>a</code>	(local). Pointer into the local memory to an array of size $lld\_a * LOC_c(ja+n-1)$. On entry, this array contains the local pieces of the n -by- n general distributed matrix $\text{sub}(A)$ to be reduced.
<code>ia, ja</code>	(global) The row and column indices in the global matrix A indicating the first row and the first column of $\text{sub}(A)$, respectively.
<code>desca</code>	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix A .
<code>work</code>	(local). This is a workspace array of size $lwork$.
<code>lwork</code>	(local or global) The size of the array $work$. $lwork$ is local input and must be at least $lwork \geq nb + \max(npa0, nb)$, where $nb = mb\_a = nb\_a$, $iroffa = \text{mod}(ia-1, nb)$, $iarow = \text{indxg2p}(ia, nb, myrow, rsrc\_a, nprow)$, $npa0 = \text{numroc}(ihi + iroffa, nb, myrow, iarow, nprow)$. <code>indxg2p</code> and <code>numroc</code> are ScaLAPACK tool functions; <code>myrow</code> , <code>mycol</code> , <code>nprow</code> , and <code>ncol</code> can be determined by calling the function <code>blacs_gridinfo</code> .

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

a	(local). On exit, the upper triangle and the first subdiagonal of $\text{sub}(A)$ are overwritten with the upper Hessenberg matrix H , and the elements below the first subdiagonal, with the array τ , represent the orthogonal/unitary matrix Q as a product of elementary reflectors. (see <i>Application Notes</i> below).
τ	(local). Array of size $LOCc(ja+n-2)$ The scalar factors of the elementary reflectors (see <i>Application Notes</i> below). Elements $ja:ja+ilo-2$ and $ja+ihi:ja+n-2$ of the global vector τ are set to zero. τ is tied to the distributed matrix A .
$work$	On exit, $work[0]$ returns the minimal and optimal $lwork$.
$info$	(local) If $info = 0$, the execution is successful. if $info < 0$: If the i -th argument is an array and the j -th entry, indexed $j-1$, had an illegal value, then $info = -(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

Application Notes

The matrix Q is represented as a product of $(ihi-ilo)$ elementary reflectors

$$Q = H(ilo)*H(ilo+1)*\dots*H(ihi-1).$$

Each $H(i)$ has the form

$$H(i) = I - \tau * v * v',$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(1:i)=0$, $v(i+1)=1$ and $v(ihi+1:n)=0$; $v(i+2:ihi)$ is stored on exit in $A(ia+ilo+i:ia+ihi-1, ia+ilo+i-2)$, and τ in $\tau[ja+ilo+i-3]$.

The contents of $A(ia:ia+n-1, ja:ja+n-1)$ are illustrated by the following example, with $n = 7$, $ilo = 2$ and $ihi = 6$:

on entry	on exit
$\begin{bmatrix} a & a & a & a & a & a & a \\ a & a & a & a & a & a & a \\ a & a & a & a & a & a & a \\ a & a & a & a & a & a & a \\ a & a & a & a & a & a & a \\ a & a & a & a & a & a & a \\ & & & & & & a \end{bmatrix}$	$\begin{bmatrix} a & a & h & h & h & h & a \\ a & h & h & h & h & h & a \\ h & h & h & h & h & h & h \\ v2 & h & h & h & h & h & h \\ v2 & v3 & h & h & h & h & h \\ v2 & v3 & v4 & h & h & h & h \\ & & & & & & a \end{bmatrix}$

where a denotes an element of the original matrix $\text{sub}(A)$, h denotes a modified element of the upper Hessenberg matrix H , and v_i denotes an element of the vector defining $H(ja+ilo+i-2)$.

*info );
```

Include Files

- `mkl_scalapack.h`

Description

The `p?gelq2` function computes an LQ factorization of a real/complex distributed m -by- n matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1) = L^*Q$.

Input Parameters

m	(global) The number of rows of the distributed matrix $\text{sub}(A)$. ($m \geq 0$).
n	(global) The number of columns of the distributed matrix $\text{sub}(A)$. ($n \geq 0$).
a	(local). Pointer into the local memory to an array of size <code>lld_a * LOcc(ja+n-1)</code> . On entry, this array contains the local pieces of the m -by- n distributed matrix $\text{sub}(A)$ which is to be factored.
ia, ja	(global) The row and column indices in the global matrix A indicating the first row and the first column of $\text{sub}(A)$, respectively.
$desca$	(global and local) array of size <code>dlen_</code> . The array descriptor for the distributed matrix A .
$work$	(local). This is a workspace array of size <code>lwork</code> .
$lwork$	(local or global)

The size of the array *work*.

lwork is local input and must be at least $lwork \geq nq0 + \max(1, mp0)$,

where $iroff = \text{mod}(ia-1, mb\_a)$, $icoff = \text{mod}(ja-1, nb\_a)$,

$iarow = \text{indxg2p}(ia, mb\_a, myrow, rsrc\_a, nprow)$,

$iacol = \text{indxg2p}(ja, nb\_a, mycol, csrc\_a, npcot)$,

$mp0 = \text{numroc}(m+iroff, mb\_a, myrow, iarow, nprow)$,

$nq0 = \text{numroc}(n+icoff, nb\_a, mycol, iacol, npcot)$,

indxg2p and numroc are ScaLAPACK tool functions; *myrow*, *mycol*, *nprow*, and *npcot* can be determined by calling the function `blacs_gridinfo`.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by [pxerbla](#).

Output Parameters

<i>a</i>	(local). On exit, the elements on and below the diagonal of sub(<i>A</i>) contain the <i>m</i> by $\min(m,n)$ lower trapezoidal matrix <i>L</i> (<i>L</i> is lower triangular if $m \leq n$); the elements above the diagonal, with the array <i>tau</i> , represent the orthogonal/unitary matrix <i>Q</i> as a product of elementary reflectors (see <i>Application Notes</i> below).
<i>tau</i>	(local). Array of size $LOCr(ia+\min(m, n)-1)$. This array contains the scalar factors of the elementary reflectors. <i>tau</i> is tied to the distributed matrix <i>A</i> .
<i>work</i>	On exit, <i>work</i> [0] returns the minimal and optimal <i>lwork</i> .
<i>info</i>	(local) If <i>info</i> = 0, the execution is successful. if <i>info</i> < 0: If the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j</i> -1, had an illegal value, then <i>info</i> = - (<i>i</i> *100+ <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

Application Notes

The matrix *Q* is represented as a product of elementary reflectors

$Q = H(ia+k-1) * H(ia+k-2) * \dots * H(ia)$ for real flavors, $Q = (H(ia+k-1))^{H*} (H(ia+k-2))^{H*} \dots (H(ia))^{H*}$ for complex flavors,

where $k = \min(m, n)$.

Each $H(i)$ has the form

$H(i) = I - \tau v v'$

where *tau* is a real/complex scalar, and *v* is a real/complex vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:n)$ (for real flavors) or $\text{conjg}(v(i+1:n))$ (for complex flavors) is stored on exit in $A(ia+i-1, ja+i:ja+n-1)$, and *tau* in $\tau[ia+i-2]$.

Description

The p?geql2 function computes a QL factorization of a real/complex distributed m -by- n matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1) = Q * L$.

Input Parameters

m	(global) The number of rows in the distributed matrix $\text{sub}(A)$. ($m \geq 0$).
n	(global) The number of columns in the distributed matrix $\text{sub}(A)$. ($n \geq 0$).
a	(local). Pointer into the local memory to an array of size $lld\_a * LOC_c(ja+n-1)$. On entry, this array contains the local pieces of the m -by- n distributed matrix $\text{sub}(A)$ which is to be factored.
ia, ja	(global) The row and column indices in the global matrix A indicating the first row and the first column of $\text{sub}(A)$, respectively.
$desca$	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix A .
$work$	(local). This is a workspace array of size $lwork$.
$lwork$	(local or global) The size of the array $work$. $lwork$ is local input and must be at least $lwork \geq mp0 + \max(1, nq0)$,

where $i_{\text{roff}} = \text{mod}(ia-1, mb\_a)$, $i_{\text{coff}} = \text{mod}(ja-1, nb\_a)$,
 $iarow = \text{indxg2p}(ia, mb\_a, myrow, rsrc\_a, nprow)$,
 $iacol = \text{indxg2p}(ja, nb\_a, mycol, csrc\_a, npcot)$,
 $mp0 = \text{numroc}(m+i_{\text{roff}}, mb\_a, myrow, iarow, nprow)$,
 $nq0 = \text{numroc}(n+i_{\text{coff}}, nb\_a, mycol, iacol, npcot)$,
 indxg2p and numroc are ScaLAPACK tool functions; $myrow$, $mycol$, $nprow$,
and $npcot$ can be determined by calling the function `blacs_gridinfo`.

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

a	(local). On exit, if $m \geq n$, the lower triangle of the distributed submatrix $A(ia+m-n:ia+m-1, ja:ja+n-1)$ contains the n -by- n lower triangular matrix L ; if $m \leq n$, the elements on and below the $(n-m)$ -th superdiagonal contain the m -by- n lower trapezoidal matrix L ; the remaining elements, with the array τ , represent the orthogonal/ unitary matrix Q as a product of elementary reflectors (see <i>Application Notes</i> below).
τ	(local). Array of size $LOCc(ja+n-1)$. This array contains the scalar factors of the elementary reflectors. τ is tied to the distributed matrix A .
$work$	On exit, $work[0]$ returns the minimal and optimal $lwork$.
$info$	(local). If $info = 0$, the execution is successful. if $info < 0$: If the i -th argument is an array and the j -th entry, indexed $j-1$, had an illegal value, then $info = -(i*100+j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

Application Notes

The matrix Q is represented as a product of elementary reflectors

$$Q = H(ja+k-1) * \dots * H(ja+1) * H(ja), \text{ where } k = \min(m, n).$$

Each $H(i)$ has the form

$$H(i) = I - \tau v v'$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(m-k+i+1:m) = 0$ and $v(m-k+i) = 1$; $v(1:m-k+i-1)$ is stored on exit in $A(ia:ia+m-k+i-2, ja+n-k+i-1)$, and τ in $\tau[ja+n-k+i-2]$.

- mkl_scalapack.h

Description

The p?geqr2 function computes a QR factorization of a real/complex distributed m -by- n matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1) = Q^*R$.

Input Parameters

m	(global) The number of rows in the distributed matrix $\text{sub}(A)$. ($m \geq 0$).
n	(global) The number of columns in the distributed matrix $\text{sub}(A)$. ($n \geq 0$).
a	(local). Pointer into the local memory to an array of size $lld\_a * LOC_c(ja+n-1)$. On entry, this array contains the local pieces of the m -by- n distributed matrix $\text{sub}(A)$ which is to be factored.
ia, ja	(global) The row and column indices in the global matrix A indicating the first row and the first column of $\text{sub}(A)$, respectively.
$desca$	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix A .
$work$	(local). This is a workspace array of size $lwork$.
$lwork$	(local or global) The size of the array $work$. $lwork$ is local input and must be at least $lwork \geq mp0 + \max(1, nq0)$, where $i\text{roff} = \text{mod}(ia-1, mb\_a)$, $i\text{coff} = \text{mod}(ja-1, nb\_a)$,

```
iarow = indxg2p(ia, mb_a, myrow, rsrc_a, nprow),
iacol = indxg2p(ja, nb_a, mycol, csrc_a, npcot),
mp0 = numroc(m+iroff, mb_a, myrow, iarow, nprow),
nq0 = numroc(n+icoff, nb_a, mycol, iacol, npcot).

indxg2p and numroc are ScaLAPACK tool functions; myrow, mycol, nprow,
and npcot can be determined by calling the function blacs_gridinfo.
```

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `p?erbla`.

Output Parameters

<i>a</i>	(local). On exit, the elements on and above the diagonal of sub(<i>A</i>) contain the $\min(m,n)$ by n upper trapezoidal matrix <i>R</i> (<i>R</i> is upper triangular if $m \geq n$); the elements below the diagonal, with the array <i>tau</i> , represent the orthogonal/unitary matrix <i>Q</i> as a product of elementary reflectors (see <i>Application Notes</i> below).
<i>tau</i>	(local). Array of size $LOCc(ja+\min(m,n)-1)$. This array contains the scalar factors of the elementary reflectors. <i>tau</i> is tied to the distributed matrix <i>A</i> .
<i>work</i>	On exit, <code>work[0]</code> returns the minimal and optimal <i>lwork</i> .
<i>info</i>	(local) If <code>info = 0</code> , the execution is successful. if <code>info < 0</code> : If the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j</i> -1, had an illegal value, then <code>info = - (i*100+j)</code> , if the <i>i</i> -th argument is a scalar and had an illegal value, then <code>info = -i</code> .

Application Notes

The matrix *Q* is represented as a product of elementary reflectors

$$Q = H(ja) * H(ja+1) * \dots * H(ja+k-1), \text{ where } k = \min(m,n).$$

Each *H(i)* has the form

$$H(j) = I - \tau * v * v',$$

where *tau* is a real/complex scalar, and *v* is a real/complex vector with $v(1:i-1) = 0$ and $v(i) = 1$; $v(i+1:m)$ is stored on exit in $A(ia+i:ia+m-1, ja+i-1)$, and *tau* in $\tau[ja+i-2]$.

Description

The `p?gqrq2` function computes an RQ factorization of a real/complex distributed m -by- n matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1) = R*Q$.

Input Parameters

<i>m</i>	(global) The number of rows in the distributed matrix $\text{sub}(A)$. ($m \geq 0$).
<i>n</i>	(global) The number of columns in the distributed matrix $\text{sub}(A)$. ($n \geq 0$).
<i>a</i>	(local). Pointer into the local memory to an array of size $lld\_a * LOC_c(ja+n-1)$. On entry, this array contains the local pieces of the m -by- n distributed matrix $\text{sub}(A)$ which is to be factored.
<i>ia, ja</i>	(global) The row and column indices in the global matrix A indicating the first row and the first column of $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix A .
<i>work</i>	(local). This is a workspace array of size <i>lwork</i> .
<i>lwork</i>	(local or global) The size of the array <i>work</i> . <i>lwork</i> is local input and must be at least $lwork \geq nq0 + \max(1, mp0)$, where $iroff = \text{mod}(ia-1, mb\_a), \quad icoff = \text{mod}(ja-1, nb\_a),$ $iarow = \text{indxg2p}(ia, mb\_a, myrow, rsrc\_a, nprow),$ $iacol = \text{indxg2p}(ja, nb\_a, mycol, csrc\_a, npc0l), \quad mp0 =$ $\text{numroc}(m+iroff, mb\_a, myrow, iarow, nprow),$ $nq0 = \text{numroc}(n+icoff, nb\_a, mycol, iacol, npc0l),$

`indxg2p` and `numroc` are ScaLAPACK tool functions; `myrow`, `mycol`, `nrow`, and `ncol` can be determined by calling the function `blacs_gridinfo`.

If `lwork = -1`, then `lwork` is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

<code>a</code>	(local). On exit, if $m \leq n$, the upper triangle of $A(ia+m-n:ia+m-1, ja:ja+n-1)$ contains the m-by-m upper triangular matrix R; if $m \geq n$, the elements on and above the $(m-n)$-th subdiagonal contain the m-by-n upper trapezoidal matrix R; the remaining elements, with the array <code>tau</code>, represent the orthogonal/ unitary matrix Q as a product of elementary reflectors (see <i>Application Notes</i> below).
<code>tau</code>	(local). Array of size $LOCr(ia+m-1)$. This array contains the scalar factors of the elementary reflectors. <code>tau</code> is tied to the distributed matrix A.
<code>work</code>	On exit, <code>work[0]</code> returns the minimal and optimal <code>lwork</code> .
<code>info</code>	(local) If <code>info = 0</code>, the execution is successful. if <code>info < 0</code>: If the i-th argument is an array and the j-th entry, indexed $j-1$, had an illegal value, then <code>info = -(i*100+j)</code>, if the i-th argument is a scalar and had an illegal value, then <code>info = -i</code>.

Application Notes

The matrix Q is represented as a product of elementary reflectors

$Q = H(ia) * H(ia+1) * \dots * H(ia+k-1)$ for real flavors,

$Q = (H(ia))^H * (H(ia+1))^H * \dots * (H(ia+k-1))^H$ for complex flavors,

where $k = \min(m, n)$.

Each $H(i)$ has the form

$H(i) = I - \tau v v'$,

where `tau` is a real/complex scalar, and v is a real/complex vector with $v(n-k+i+1:n) = 0$ and $v(n-k+i) = 1$; $v(1:n-k+i-1)$ for real flavors or `conjg(v(1:n-k+i-1))` for complex flavors is stored on exit in $A(ia+m-k+i-1, ja:ja+n-k+i-2)$, and `tau` in `tau[ia+m-k+i-2]`.

p?getf2

Computes an LU factorization of a general matrix, using partial pivoting with row interchanges (local blocked algorithm).

Syntax

```
void psgetf2 (MKL_INT *m , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , MKL_INT *ipiv , MKL_INT *info );
```

```
void pdgetf2 (MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_INT *ipiv , MKL_INT *info );
```

```
void pcgetf2 (MKL_INT *m , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_INT *ipiv , MKL_INT *info );
```

```
void pzgetf2 (MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_INT *ipiv , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The `p?getf2` function computes an LU factorization of a general m -by- n distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$ using partial pivoting with row interchanges.

The factorization has the form $\text{sub}(A) = P * L * U$, where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if $m \geq n$), and U is upper triangular (upper trapezoidal if $m < n$). This is the right-looking Parallel Level 2 BLAS version of the algorithm.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. Notice revision #20110804

Input Parameters

m	(global) The number of rows in the distributed matrix $\text{sub}(A)$. ($m \geq 0$).
n	(global) The number of columns in the distributed matrix $\text{sub}(A)$. ($nb\_a - \text{mod}(ja-1, nb\_a) \geq n \geq 0$).
a	(local). Pointer into the local memory to an array of size $lld\_a * LOC_c(ja+n-1)$.

On entry, this array contains the local pieces of the m -by- n distributed matrix $\text{sub}(A)$.

ia, ja (global) The row and column indices in the global matrix A indicating the first row and the first column of the matrix $\text{sub}(A)$, respectively.

desca (global and local) array of size $dlen\_$. The array descriptor for the distributed matrix A .

Output Parameters

ipiv (local)
Array of size $(LOCr(m\_a) + mb\_a)$. This array contains the pivoting information. *ipiv*[i] $\rightarrow$ The global row that local row $(i + 1)$ was swapped with, $i = 0, 1, \dots, LOCr(m\_a) + mb\_a - 1$. This array is tied to the distributed matrix A .

info (local).
If *info* = 0: successful exit.
If *info* < 0:

- if the i -th argument is an array and the j -th entry, indexed $j-1$, had an illegal value, then *info* = $-(i*100+j)$,
- if the i -th argument is a scalar and had an illegal value, then *info* = $-i$.

If *info* > 0: If *info* = k , the matrix element $U(ia+k-1, ja+k-1)$ is exactly zero. The factorization has been completed, but the factor U is exactly singular, and division by zero will occur if it is used to solve a system of equations.

```

Include Files

- mkl_scalapack.h

Description

The `p?labrd` function reduces the first nb rows and columns of a real/complex general m -by- n distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$ to upper or lower bidiagonal form by an orthogonal/unitary transformation $Q'^* A * P$, and returns the matrices X and Y necessary to apply the transformation to the unreduced part of $\text{sub}(A)$.

If $m \geq n$, $\text{sub}(A)$ is reduced to upper bidiagonal form; if $m < n$, $\text{sub}(A)$ is reduced to lower bidiagonal form.

This is an auxiliary function called by `p?gebrd`.

Input Parameters

m	(global) The number of rows in the distributed matrix $\text{sub}(A)$. ($m \geq 0$).
n	(global) The number of columns in the distributed matrix $\text{sub}(A)$. ($n \geq 0$).
nb	(global) The number of leading rows and columns of $\text{sub}(A)$ to be reduced.
a	(local). Pointer into the local memory to an array of size $lld\_a * LOC_c(ja+n-1)$. On entry, this array contains the local pieces of the general distributed matrix $\text{sub}(A)$.
ia, ja	(global) The row and column indices in the global matrix A indicating the first row and the first column of the matrix $\text{sub}(A)$, respectively.
$desca$	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix A .
ix, jx	(global) The row and column indices in the global matrix X indicating the first row and the first column of the matrix $\text{sub}(X)$, respectively.
$descx$	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix X .
iy, jy	(global) The row and column indices in the global matrix Y indicating the first row and the first column of the matrix $\text{sub}(Y)$, respectively.
$descy$	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix Y .

work (local).
 Workspace array of size *lwork*.
 $lwork \geq nb\_a + nq$,
 with $nq = \text{numroc}(n + \text{mod}(ia-1, nb\_y), nb\_y, mycol, iacol, npcol)$
 $iacol = \text{indxg2p}(ja, nb\_a, mycol, csrc\_a, npcol)$
 indxg2p and numroc are ScaLAPACK tool functions; *myrow*, *mycol*, *nprow*, and *npcol* can be determined by calling the function `blacs_gridinfo`.

Output Parameters

a (local)
 On exit, the first *nb* rows and columns of the matrix are overwritten; the rest of the distributed matrix `sub(A)` is unchanged.
 If $m \geq n$, elements on and below the diagonal in the first *nb* columns, with the array *tauq*, represent the orthogonal/unitary matrix *Q* as a product of elementary reflectors; and elements above the diagonal in the first *nb* rows, with the array *taup*, represent the orthogonal/unitary matrix *P* as a product of elementary reflectors.
 If $m < n$, elements below the diagonal in the first *nb* columns, with the array *tauq*, represent the orthogonal/unitary matrix *Q* as a product of elementary reflectors, and elements on and above the diagonal in the first *nb* rows, with the array *taup*, represent the orthogonal/unitary matrix *P* as a product of elementary reflectors. See *Application Notes* below.

d (local).
 Array of size $LOCr(ia + \min(m, n) - 1)$ if $m \geq n$; $LOCc(ja + \min(m, n) - 1)$ otherwise. The distributed diagonal elements of the bidiagonal distributed matrix *B*:
 $d[i] = A(ia+i, ja+i), i = 0, 1, \dots, \text{size}(d)-1$
d is tied to the distributed matrix *A*.

e (local).
 Array of size $LOCr(ia + \min(m, n) - 1)$ if $m \geq n$; $LOCc(ja + \min(m, n) - 2)$ otherwise. The distributed off-diagonal elements of the bidiagonal distributed matrix *B*:
 if $m \geq n$, $e[i] = A(ia+i, ja+i+1)$ for $i = 0, 1, \dots, n-2$;
 if $m < n$, $e[i] = A(ia+i+1, ja+i)$ for $i = 0, 1, \dots, m-2$.
e is tied to the distributed matrix *A*.

tauq, taup (local).
 Array size $LOCc(ja + \min(m, n) - 1)$ for *tauq*, size $LOCr(ia + \min(m, n) - 1)$ for *taup*. The scalar factors of the elementary reflectors which represent the orthogonal/unitary matrix *Q* for *tauq*, *P* for *taup*. *tauq* and *taup* are tied to the distributed matrix *A*. See *Application Notes* below.

x (local)

Pointer into the local memory to an array of size $lld\_x * nb$. On exit, the local pieces of the distributed m -by- nb matrix $X(ix:ix+m-1, jx:jx+nb-1)$ required to update the unreduced part of $sub(A)$.

y

(local).

Pointer into the local memory to an array of size $lld\_y * nb$. On exit, the local pieces of the distributed n -by- nb matrix $Y(iy:iy+n-1, jy:jy+nb-1)$ required to update the unreduced part of $sub(A)$.

Application Notes

The matrices Q and P are represented as products of elementary reflectors:

$$Q = H(1) * H(2) * \dots * H(nb), \text{ and } P = G(1) * G(2) * \dots * G(nb)$$

Each $H(i)$ and $G(i)$ has the form:

$$H(i) = I - \tau_{auq} v v', \text{ and } G(i) = I - \tau_{aup} u u',$$

where τ_{auq} and τ_{aup} are real/complex scalars, and v and u are real/complex vectors.

If $m \geq n$, $v(1:i-1) = 0$, $v(i) = 1$, and $v(i:m)$ is stored on exit in

$A(ia+i-1:ia+m-1, ja+i-1)$; $u(1:i) = 0$, $u(i+1) = 1$, and $u(i+1:n)$ is stored on exit in $A(ia+i-1, ja+i:jn+n-1)$; τ_{auq} is stored in $\tau_{auq}[ja+i-2]$ and τ_{aup} in $\tau_{aup}[ia+i-2]$.

If $m < n$, $v(1:i) = 0$, $v(i+1) = 1$, and $v(i+1:m)$ is stored on exit in

$A(ia+i+1:ia+m-1, ja+i-1)$; $u(1:i-1) = 0$, $u(i) = 1$, and $u(i:n)$ is stored on exit in $A(ia+i-1, ja+i:jn+n-1)$; τ_{auq} is stored in $\tau_{auq}[ja+i-2]$ and τ_{aup} in $\tau_{aup}[ia+i-2]$. The elements of the vectors v and u together form the m -by- nb matrix V and the nb -by- n matrix U' which are necessary, with X and Y , to apply the transformation to the unreduced part of the matrix, using a block update of the form: $sub(A) := sub(A) - V * Y' - X * U'$. The contents of $sub(A)$ on exit are illustrated by the following examples with $nb = 2$:

$m = 6$ and $n = 5 (m > n)$:

$$\begin{bmatrix} 1 & 1 & u1 & u1 & u1 \\ v1 & 1 & 1 & u2 & u2 \\ v1 & v2 & a & a & a \\ v1 & v2 & a & a & a \\ v1 & v2 & a & a & a \\ v1 & v2 & a & a & a \end{bmatrix}$$

$m = 5$ and $n = 6 (m < n)$:

$$\begin{bmatrix} 1 & u1 & u1 & u1 & u1 & u1 \\ 1 & 1 & u2 & u2 & u2 & u2 \\ v1 & 1 & a & a & a & a \\ v1 & v2 & a & a & a & a \\ v1 & v2 & a & a & a & a \end{bmatrix}$$

where a denotes an element of the original matrix which is unchanged, vi denotes an element of the vector defining $H(i)$, and ui an element of the vector defining $G(i)$.

p?lacon

Estimates the 1-norm of a square matrix, using the reverse communication for evaluating matrix-vector products.

Syntax

```
void pslacon (MKL_INT *n , float *v , MKL_INT *iv , MKL_INT *jv , MKL_INT *descv ,
float *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx , MKL_INT *isgn , float *est ,
MKL_INT *kase );
```

```
void pdlacon (MKL_INT *n , double *v , MKL_INT *iv , MKL_INT *jv , MKL_INT *descv ,
double *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx , MKL_INT *isgn , double *est ,
MKL_INT *kase );

void pclacon (MKL_INT *n , MKL_Complex8 *v , MKL_INT *iv , MKL_INT *jv , MKL_INT
*descv , MKL_Complex8 *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx , float *est ,
MKL_INT *kase );

void pzlacon (MKL_INT *n , MKL_Complex16 *v , MKL_INT *iv , MKL_INT *jv , MKL_INT
*descv , MKL_Complex16 *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx , double *est ,
MKL_INT *kase );
```

Include Files

- mkl_scalapack.h

Description

The `p?lacon` function estimates the 1-norm of a square, real/unitary distributed matrix A . Reverse communication is used for evaluating matrix-vector products. x and v are aligned with the distributed matrix A , this information is implicitly contained within iv , ix , $descv$, and $descx$.

Input Parameters

n	(global) The length of the distributed vectors v and x . $n \geq 0$.
v	(local). Pointer into the local memory to an array of size $LOCr(n+\text{mod}(iv-1, mb_v))$. On the final return, $v = a*w$, where $est = \text{norm}(v)/\text{norm}(w)$ (w is not returned).
iv, jv	(global) The row and column indices in the global matrix V indicating the first row and the first column of the submatrix V , respectively.
$descv$	(global and local) array of size $dlen_$. The array descriptor for the distributed matrix V .
x	(local). Pointer into the local memory to an array of size $LOCr(n+\text{mod}(ix-1, mb_x))$.
ix, jx	(global) The row and column indices in the global matrix X indicating the first row and the first column of the submatrix X , respectively.
$descx$	(global and local) array of size $dlen_$. The array descriptor for the distributed matrix X .
$isgn$	(local). Array of size $LOCr(n+\text{mod}(ix-1, mb_x))$. $isgn$ is aligned with x and v .
$kase$	(local). On the initial call to <code>p?lacon</code> , $kase$ should be 0.

Output Parameters

x	(local).

On an intermediate return, X should be overwritten by A^*X , if $kase=1$, $A^T X$, if $kase=2$,

`p?lacon` must be re-called with all the other parameters unchanged.

`est` (global).

`kase` (local)

On an intermediate return, $kase$ is 1 or 2, indicating whether X should be overwritten by A^*X , or $A^T X$. On the final return from `p?lacon`, $kase$ is again 0.

See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

p?laconsb

Looks for two consecutive small subdiagonal elements.

Syntax

```
void pslaconsb (float *a , MKL_INT *desca , MKL_INT *i , MKL_INT *l , MKL_INT *m ,
float *h44 , float *h33 , float *h43h34 , float *buf , MKL_INT *lwork );
```

```
void pdlaconsb (double *a , MKL_INT *desca , MKL_INT *i , MKL_INT *l , MKL_INT *m ,
double *h44 , double *h33 , double *h43h34 , double *buf , MKL_INT *lwork );
```

Include Files

- `mk1_scalapack.h`

Description

The `p?laconsb` function looks for two consecutive small subdiagonal elements by analyzing the effect of starting a double shift QR iteration given by $h44$, $h33$, and $h43h34$ to see if this process makes a subdiagonal negligible.

Input Parameters

`a` (global).

Array of size $lld_a * LOCc(n_a)$. On entry, the Hessenberg matrix whose tridiagonal part is being scanned. Unchanged on exit.

`desca` (global and local)

Array of size $dlen_$. The array descriptor for the distributed matrix A .

`i` (global)

The global location of the bottom of the unreduced submatrix of A . Unchanged on exit.

`l` (global)

The global location of the top of the unreduced submatrix of A . Unchanged on exit.

$h44$, $h33$, $h43h34$ (global).

These three values are for the double shift QR iteration.

lwork

(local or global)

This must be at least $7 * \text{ceil}(\text{ceil}((i-1)/hbl) / \text{lcm}(nprow, npcol))$. Here *lcm* is least common multiple and *nprow*ncol* is the logical grid size.

Output Parameters

m

(global). On exit, this yields the starting location of the QR double shift. This will satisfy:

$i \leq m \leq i-2$.

buf

(local).

Array of size *lwork*.

lwork

(local or global). On exit, *lwork* is the size of the work buffer.

See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

p?lacp2

Copies all or part of a distributed matrix to another distributed matrix.

Syntax

```
void pslacp2 (char *uplo , MKL_INT *m , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb );

void pdlacp2 (char *uplo , MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb );

void pclacp2 (char *uplo , MKL_INT *m , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb );

void pzlacp2 (char *uplo , MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb );
```

Include Files

- mkl_scalapack.h

Description

The p?lacp2 function copies all or part of a distributed matrix *A* to another distributed matrix *B*. No communication is performed, p?lacp2 performs a local copy $\text{sub}(A) := \text{sub}(B)$, where $\text{sub}(A)$ denotes $A(ia:ia+m-1, a:ja+n-1)$ and $\text{sub}(B)$ denotes $B(ib:ib+m-1, jb:jb+n-1)$.

p?lacp2 requires that only dimension of the matrix operands is distributed.

Input Parameters

uplo

(global) Specifies the part of the distributed matrix $\text{sub}(A)$ to be copied:

= 'U': Upper triangular part is copied; the strictly lower triangular part of sub(A) is not referenced;

= 'L': Lower triangular part is copied; the strictly upper triangular part of sub(A) is not referenced.

Otherwise: all of the matrix sub(A) is copied.

<i>m</i>	(global) The number of rows in the distributed matrix sub(A). ($m \geq 0$).
<i>n</i>	(global) The number of columns in the distributed matrix sub(A). ($n \geq 0$).
<i>a</i>	(local). Pointer into the local memory to an array of size $lld\_a * LOCC(ja+n-1)$. On entry, this array contains the local pieces of the <i>m</i> -by- <i>n</i> distributed matrix sub(A).
<i>ia, ja</i>	(global) The row and column indices in the global matrix A indicating the first row and the first column of sub(A), respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix A.
<i>ib, jb</i>	(global) The row and column indices in the global matrix B indicating the first row and the first column of sub(B), respectively.
<i>descb</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix B.

Output Parameters

<i>b</i>	(local). Pointer into the local memory to an array of size $lld\_b * LOCC(jb+n-1)$. This array contains on exit the local pieces of the distributed matrix sub(B) set as follows: if <i>uplo</i> = 'U', $B(ib+i-1, jb+j-1) = A(ia+i-1, ja+j-1)$, $1 \leq j \leq n$; if <i>uplo</i> = 'L', $B(ib+i-1, jb+j-1) = A(ia+i-1, ja+j-1)$, $j \leq m$, $1 \leq j \leq n$; otherwise, $B(ib+i-1, jb+j-1) = A(ia+i-1, ja+j-1)$, $1 \leq m$, $1 \leq j \leq n$.

p?lacc3

Copies from a global parallel array into a local replicated array or vice versa.

Syntax

```
void pslacc3 (MKL_INT *m , MKL_INT *i , float *a , MKL_INT *desca , float *b , MKL_INT
*ldb , MKL_INT *ii , MKL_INT *jj , MKL_INT *rev );
```

```
void pdlaccp3 (MKL_INT *m , MKL_INT *i , double *a , MKL_INT *desca , double *b ,
MKL_INT *ldb , MKL_INT *ii , MKL_INT *jj , MKL_INT *rev );
```

Include Files

- mkl_scalapack.h

Description

This is an auxiliary function that copies from a global parallel array into a local replicated array or vice versa. Note that the entire submatrix that is copied gets placed on one node or more. The receiving node can be specified precisely, or all nodes can receive, or just one row or column of nodes.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

<i>m</i>	(global) <i>m</i> is the order of the square submatrix that is copied. $m \geq 0$. Unchanged on exit.
<i>i</i>	(global) The matrix element $A(i, i)$ is the global location that the copying starts from. Unchanged on exit.
<i>a</i>	(global). Array of size $lld\_a * LOCc(n\_a)$. On entry, the parallel matrix to be copied into or from.
<i>desca</i>	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix <i>A</i> .
<i>b</i>	(local). Array of size <i>ldb</i> by <i>m</i> . If <i>rev</i> = 0, this is the global portion of the matrix $A(i:i+m-1, i:i+m-1)$. If <i>rev</i> = 1, this is unchanged on exit.
<i>ldb</i>	(local) The leading dimension of <i>B</i> .
<i>ii</i>	(global) By using <i>rev</i> 0 and 1, data can be sent out and returned again. If <i>rev</i> = 0, then <i>ii</i> is destination row index for the node(s) receiving the replicated matrix <i>B</i> . If $ii \geq 0, jj \geq 0$, then node (<i>ii</i> , <i>jj</i>) receives the data. If $ii = -1, jj \geq 0$, then all rows in column <i>jj</i> receive the data. If $ii \geq 0, jj = -1$, then

all cols in row ii receive the data. If $ii = -1, jj = -1$, then all nodes receive the data. If $rev \neq 0$, then ii is the source row index for the node(s) sending the replicated B .

jj (global) Similar description as ii above.

rev (global) Use $rev = 0$ to send global matrix A into locally replicated matrix B (on node (ii, jj)). Use $rev \neq 0$ to send locally replicated B from node (ii, jj) to its owner (which changes depending on its location in A) into the global A .

Output Parameters

a (global). On exit, if $rev = 1$, the copied data. Unchanged on exit if $rev = 0$.

b (local). If $rev = 1$, this is unchanged on exit.

p?lacpy

Copies all or part of one two-dimensional array to another.

Syntax

```
void pslacpy (char *uplo , MKL_INT *m , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb );
```

```
void pdlacpy (char *uplo , MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb );
```

```
void pclacpy (char *uplo , MKL_INT *m , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb );
```

```
void pzlacpy (char *uplo , MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb );
```

Include Files

- mkl_scalapack.h

Description

The `p?lacpy` function copies all or part of a distributed matrix A to another distributed matrix B . No communication is performed, `p?lacpy` performs a local copy $\text{sub}(B) := \text{sub}(A)$, where $\text{sub}(A)$ denotes $A(ia:ia+m-1, ja:ja+n-1)$ and $\text{sub}(B)$ denotes $B(ib:ib+m-1, jb:jb+n-1)$.

Input Parameters

$uplo$ (global) Specifies the part of the distributed matrix $\text{sub}(A)$ to be copied:
= 'U': Upper triangular part; the strictly lower triangular part of $\text{sub}(A)$ is not referenced;

= 'L': Lower triangular part; the strictly upper triangular part of sub(A) is not referenced.

Otherwise: all of the matrix sub(A) is copied.

m

(global)

The number of rows in the distributed matrix sub(A). ($m \geq 0$).

n

(global)

The number of columns in the distributed matrix sub(A). ($n \geq 0$).

a

(local).

Pointer into the local memory to an array of size $lld\_a * LOCC(ja+n-1)$.

On entry, this array contains the local pieces of the distributed matrix sub(A).

ia, ja

(global) The row and column indices in the global matrix A indicating the first row and the first column of the matrix sub(A), respectively.

desca

(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix A.

ib, jb

(global) The row and column indices in the global matrix B indicating the first row and the first column of sub(B) respectively.

descb

(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix A.

Output Parameters

b

(local).

Pointer into the local memory to an array of size $lld\_b * LOCC(jb+n-1)$.

This array contains on exit the local pieces of the distributed matrix sub(B) set as follows:

if $uplo = 'U'$, $B(ib+i-1, jb+j-1) = A(ia+i-1, ja+j-1)$, $1 \leq i \leq j$, $1 \leq j \leq n$;

if $uplo = 'L'$, $B(ib+i-1, jb+j-1) = A(ia+i-1, ja+j-1)$, $j \leq i \leq m$, $1 \leq j \leq n$;

otherwise, $B(ib+i-1, jb+j-1) = A(ia+i-1, ja+j-1)$, $1 \leq i \leq m$, $1 \leq j \leq n$.

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

p?laevswp

Moves the eigenvectors from where they are computed to ScaLAPACK standard block cyclic array.

Syntax

```
void pslaevswp (MKL_INT *n , float *zin , MKL_INT *ldzi , float *z , MKL_INT *iz ,
MKL_INT *jz , MKL_INT *descz , MKL_INT *nvs , MKL_INT *key , float *work , MKL_INT
*lwork );
```

```

void pdlaevswp (MKL_INT *n , double *zin , MKL_INT *ldzi , double *z , MKL_INT *iz ,
MKL_INT *jz , MKL_INT *descz , MKL_INT *nvs , MKL_INT *key , double *work , MKL_INT
*lwork );

void pclaevswp (MKL_INT *n , float *zin , MKL_INT *ldzi , MKL_Complex8 *z , MKL_INT
*iz , MKL_INT *jz , MKL_INT *descz , MKL_INT *nvs , MKL_INT *key , float *rwork ,
MKL_INT *lrwork );

void pzlaevswp (MKL_INT *n , double *zin , MKL_INT *ldzi , MKL_Complex16 *z , MKL_INT
*iz , MKL_INT *jz , MKL_INT *descz , MKL_INT *nvs , MKL_INT *key , double *rwork ,
MKL_INT *lrwork );

```

Include Files

- mkl_scalapack.h

Description

The `p?laevswp` function moves the eigenvectors (potentially unsorted) from where they are computed, to a ScaLAPACK standard block cyclic array, sorted so that the corresponding eigenvalues are sorted.

Input Parameters

np = the number of rows local to a given process.

nq = the number of columns local to a given process.

n	(global) The order of the matrix A . $n \geq 0$.
zin	(local). Array of size $ldzi * nvs[iam+1]$. The eigenvectors on input. iam is a process rank from $[0, nprocs)$ interval. Each eigenvector resides entirely in one process. Each process holds a contiguous set of $nvs[iam+1]$ eigenvectors. The global number of the first eigenvector that the process holds is: ((sum for $i=[0, iam]$ of $nvs[i]$)+1).
$ldzi$	(local) The leading dimension of the zin array.
iz, jz	(global) The row and column indices in the global matrix Z indicating the first row and the first column of the submatrix Z , respectively.
$descz$	(global and local) Array of size $dlen\_$. The array descriptor for the distributed matrix Z .
nvs	(global) Array of size $nprocs+1$ $nvs[i]$ = number of eigenvectors held by processes $[0, i)$ $nvs[0]$ = number of eigenvectors held by processes $[0, 0) = 0$ $nvs[nprocs]$ = number of eigenvectors held by $[0, nprocs)$ = total number of eigenvectors.
key	(global)

Array of size n . Indicates the actual index (after sorting) for each of the eigenvectors.

rwork

(local).

Array of size *lrwork*.

lrwork

(local)

Size of *work*.

Output Parameters

z

(local).

Array of global size $n * n$ and of local size $dlen\_ * nq$. The eigenvectors on output. The eigenvectors are distributed in a block cyclic manner in both dimensions, with a block size of *nb*.

p?lahrd

Reduces the first nb columns of a general rectangular matrix A so that elements below the k -th subdiagonal are zero, by an orthogonal/unitary transformation, and returns auxiliary matrices that are needed to apply the transformation to the unreduced part of A .

Syntax

```
void pslahrd (MKL_INT *n , MKL_INT *k , MKL_INT *nb , float *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , float *tau , float *t , float *y , MKL_INT *iy , MKL_INT *jy ,
MKL_INT *descy , float *work );
```

```
void pdlahrd (MKL_INT *n , MKL_INT *k , MKL_INT *nb , double *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , double *tau , double *t , double *y , MKL_INT *iy ,
MKL_INT *jy , MKL_INT *descy , double *work );
```

```
void pclahrd (MKL_INT *n , MKL_INT *k , MKL_INT *nb , MKL_Complex8 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *tau , MKL_Complex8 *t , MKL_Complex8 *y ,
MKL_INT *iy , MKL_INT *jy , MKL_INT *descy , MKL_Complex8 *work );
```

```
void pzlahrd (MKL_INT *n , MKL_INT *k , MKL_INT *nb , MKL_Complex16 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *tau , MKL_Complex16 *t , MKL_Complex16
*y , MKL_INT *iy , MKL_INT *jy , MKL_INT *descy , MKL_Complex16 *work );
```

Include Files

- mkl_scalapack.h

Description

The `p?lahrd` function reduces the first nb columns of a real general n -by- $(n-k+1)$ distributed matrix $A(ia:ia+n-1, ja:ja+n-k)$ so that elements below the k -th subdiagonal are zero. The reduction is performed by an orthogonal/unitary similarity transformation Q^*A^*Q . The function returns the matrices V and T which determine Q as a block reflector $I-V^*T^*V'$, and also the matrix $Y = A^*V^*T$.

This is an auxiliary function called by `p?gehrd`. In the following comments $\text{sub}(A)$ denotes $A(ia:ia+n-1, ja:ja+n-1)$.

Input Parameters

n	(global) The order of the distributed matrix $\text{sub}(A)$. $n \geq 0$.
k	(global) The offset for the reduction. Elements below the k -th subdiagonal in the first nb columns are reduced to zero.
nb	(global) The number of columns to be reduced.
a	(local). Pointer into the local memory to an array of size $lld\_a * LOCC(j_{a+n-k})$. On entry, this array contains the local pieces of the n -by- $(n-k+1)$ general distributed matrix $A(i_a:i_{a+n-1}, j_a:j_{a+n-k})$.
ia, ja	(global) The row and column indices in the global matrix A indicating the first row and the first column of the matrix $\text{sub}(A)$, respectively.
$desca$	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix A .
iy, jy	(global) The row and column indices in the global matrix Y indicating the first row and the first column of the matrix $\text{sub}(Y)$, respectively.
$descy$	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix Y .
$work$	(local). Array of size nb .

Output Parameters

a	(local). On exit, the elements on and above the k -th subdiagonal in the first nb columns are overwritten with the corresponding elements of the reduced distributed matrix; the elements below the k -th subdiagonal, with the array τ , represent the matrix Q as a product of elementary reflectors. The other columns of the matrix $A(i_a:i_{a+n-1}, j_a:j_{a+n-k})$ are unchanged. (See <i>Application Notes</i> below.)
τ	(local) Array of size $LOCC(j_{a+n-2})$. The scalar factors of the elementary reflectors (see <i>Application Notes</i> below). τ is tied to the distributed matrix A .
t	(local) Array of size $nb\_a * nb\_a$. The upper triangular matrix T .
y	(local).

Pointer into the local memory to an array of size $lld\_y * nb\_a$. On exit, this array contains the local pieces of the n -by- nb distributed matrix Y . $lld\_y \geq LOCr(ia+n-1)$.

Application Notes

The matrix Q is represented as a product of nb elementary reflectors

$$Q = H(1) * H(2) * \dots * H(nb).$$

Each $H(i)$ has the form

$$H(i) = I - \tau v v',$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(1:i+k-1) = 0$, $v(i+k) = 1$; $v(i+k+1:n)$ is stored on exit in $A(ia+i+k:ia+n-1, ja+i-1)$, and τ in $\tau[i-2]$.

The elements of the vectors v together form the $(n-k+1)$ -by- nb matrix V which is needed, with T and Y , to apply the transformation to the unreduced part of the matrix, using an update of the form: $A(ia:ia+n-1, ja:ja+n-k) := (I - V * T * V') * (A(ia:ia+n-1, ja:ja+n-k) - Y * V')$. The contents of $A(ia:ia+n-1, ja:ja+n-k)$ on exit are illustrated by the following example with $n = 7$, $k = 3$, and $nb = 2$:

$$\begin{bmatrix} a & h & a & a & a \\ a & h & a & a & a \\ a & h & a & a & a \\ h & h & a & a & a \\ v1 & h & a & a & a \\ v1 & v2 & a & a & a \\ v1 & v2 & a & a & a \end{bmatrix}$$

where a denotes an element of the original matrix $A(ia:ia+n-1, ja:ja+n-k)$, h denotes a modified element of the upper Hessenberg matrix H , and vi denotes an element of the vector defining $H(i)$.

See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

p?laiect

Exploits IEEE arithmetic to accelerate the computations of eigenvalues.

Syntax

```
void pslaiect (float *sigma , MKL_INT *n , float *d , MKL_INT *count );
void pdlaiectb (float *sigma , MKL_INT *n , float *d , MKL_INT *count );
void pdlaiectl (float *sigma , MKL_INT *n , float *d , MKL_INT *count );
```

Include Files

- `mk1_scalapack.h`

Description

The `p?laiect` function computes the number of negative eigenvalues of $(A - \sigma I)$. This implementation of the Sturm Sequence loop exploits IEEE arithmetic and has no conditionals in the innermost loop. The signbit for real function `pslaiect` is assumed to be bit 32. Double-precision functions `pdlaiectb` and `pdlaiectl` differ

in the order of the double precision word storage and, consequently, in the signbit location. For `pdlaiectb`, the double precision word is stored in the big-endian word order and the signbit is assumed to be bit 32. For `pdlaiectl`, the double precision word is stored in the little-endian word order and the signbit is assumed to be bit 64.

This is a ScaLAPACK internal function and arguments are not checked for unreasonable values.

Input Parameters

<i>sigma</i>	The shift. <code>p?laiect</code> finds the number of eigenvalues less than equal to <i>sigma</i> .
<i>n</i>	The order of the tridiagonal matrix <i>T</i> . $n \geq 1$.
<i>d</i>	Array of size $2n-1$. On entry, this array contains the diagonals and the squares of the off-diagonal elements of the tridiagonal matrix <i>T</i> . These elements are assumed to be interleaved in memory for better cache performance. The diagonal entries of <i>T</i> are in the entries <i>d</i> [0], <i>d</i> [2], ..., <i>d</i> [2 <i>n</i> -2], while the squares of the off-diagonal entries are <i>d</i> [1], <i>d</i> [3], ..., <i>d</i> [2 <i>n</i> -3]. To avoid overflow, the matrix must be scaled so that its largest entry is no greater than $\text{overflow}^{(1/2)} * \text{underflow}^{(1/4)}$ in absolute value, and for greatest accuracy, it should not be much smaller than that.

Output Parameters

<i>n</i>	The count of the number of eigenvalues of <i>T</i> less than or equal to <i>sigma</i> .

See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

p?lamve

Copies all or part of one two-dimensional distributed array to another.

Syntax

```
void pslamve(char* uplo, MKL_INT* m, MKL_INT* n, float* a, MKL_INT* ia, MKL_INT* ja,
MKL_INT* desca, float* b, MKL_INT* ib, MKL_INT* jb, MKL_INT* descb, float* dwork);

void pdlamve(char* uplo, MKL_INT* m, MKL_INT* n, double* a, MKL_INT* ia, MKL_INT* ja,
MKL_INT* desca, double* b, MKL_INT* ib, MKL_INT* jb, MKL_INT* descb, double* dwork);
```

Include Files

- `mkl_scalapack.h`

Description

`p?lamve` copies all or part of a distributed matrix *A* to another distributed matrix *B*. There is no alignment assumptions at all except that *A* and *B* are of the same size.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

<i>uplo</i>	(global) Specifies the part of the distributed matrix sub(<i>A</i>) to be copied: = 'U': Upper triangular part is copied; the strictly lower triangular part of sub(<i>A</i>) is not referenced; = 'L': Lower triangular part is copied; the strictly upper triangular part of sub(<i>A</i>) is not referenced; Otherwise: All of the matrix sub(<i>A</i>) is copied.
<i>m</i>	(global) The number of rows to be operated on, which is the number of rows of the distributed matrix sub(<i>A</i>). $m \geq 0$.
<i>n</i>	(global) The number of columns to be operated on, which is the number of columns of the distributed matrix sub(<i>A</i>). $n \geq 0$.
<i>a</i>	(local) pointer into the local memory to an array of size $lld\_a * LOC_c(ja + n - 1)$. This array contains the local pieces of the distributed matrix sub(<i>A</i>) to be copied from.
<i>ia</i>	(global) The row index in the global matrix <i>A</i> indicating the first row of sub(<i>A</i>).
<i>ja</i>	(global) The column index in the global matrix <i>A</i> indicating the first column of sub(<i>A</i>).
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .
<i>ib</i>	(global) The row index in the global matrix <i>B</i> indicating the first row of sub(<i>B</i>).
<i>jb</i>	(global) The column index in the global matrix <i>B</i> indicating the first column of sub(<i>B</i>).

descb (global and local) array of size *dlen_*.
The array descriptor for the distributed matrix *B*.

dwork (local workspace) array
If *uplo* = 'U' or *uplo* = 'L' and number of processors > 1, the length of *dwork* is at least as large as the length of *b*.
Otherwise, *dwork* is not referenced.

OUTPUT Parameters

b (local) pointer into the local memory to an array of size *lld_b* * *LOC_c(jb + n - 1)* . This array contains on exit the local pieces of the distributed matrix sub(*B*).

See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

p?lange

Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of a general rectangular matrix.

Syntax

```
float pslange (char *norm , MKL_INT *m , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *work );

double pdlange (char *norm , MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *work );

float pclange (char *norm , MKL_INT *m , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *work );

double pzlange (char *norm , MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *work );
```

Include Files

- `mkl_scalapack.h`

Description

The `p?lange` function returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$.

Input Parameters

norm (global) Specifies what value is returned by the function:

- = 'M' or 'm': $val = \max(\text{abs}(A_{ij}))$, largest absolute value of the matrix *A*, it s not a matrix norm.
- = '1' or 'O' or 'o': $val = \text{norm1}(A)$, 1-norm of the matrix *A* (maximum column sum),
- = 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix *A* (maximum row sum),

= 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix A (square root of sum of squares).

m	(global) The number of rows in the distributed matrix $\text{sub}(A)$. When $m = 0$, $p?lange$ is set to zero. $m \geq 0$.
n	(global) The number of columns in the distributed matrix $\text{sub}(A)$. When $n = 0$, $p?lange$ is set to zero. $n \geq 0$.
a	(local). Pointer into the local memory to an array of size $lld\_a * LOCC(ja+n-1)$ containing the local pieces of the distributed matrix $\text{sub}(A)$.
ia, ja	(global) The row and column indices in the global matrix A indicating the first row and the first column of the matrix $\text{sub}(A)$, respectively.
$desca$	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix A .
$work$	(local). Array size $lwork$. $lwork \geq 0$ if $norm = 'M'$ or $'m'$ (not referenced), $nq0$ if $norm = '1', 'O'$ or $'o'$, $mp0$ if $norm = 'I'$ or $'i'$, 0 if $norm = 'F', 'f', 'E'$ or $'e'$ (not referenced), where $irow = \text{mod}(ia-1, mb\_a)$, $icoffa = \text{mod}(ja-1, nb\_a)$, $iarow = \text{indxg2p}(ia, mb\_a, myrow, rsrc\_a, nprow)$, $iacol = \text{indxg2p}(ja, nb\_a, mycol, csrc\_a, npc1)$, $mp0 = \text{numroc}(m+irow, mb\_a, myrow, iarow, nprow)$, $nq0 = \text{numroc}(n+icoffa, nb\_a, mycol, iacol, npc1)$, indxg2p and numroc are ScaLAPACK tool functions; $myrow$, $mycol$, $nprow$, and $npcol$ can be determined by calling the function <code>blacs_gridinfo</code> .

Output Parameters

val The value returned by the function.

See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

p?lanhs

Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of an upper Hessenberg matrix.

Syntax

```
float pslanhs (char *norm , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , float *work );

double pdlanhs (char *norm , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *work );

float pclanhs (char *norm , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , float *work );

double pzlanhs (char *norm , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , double *work );
```

Include Files

- mkl_scalapack.h

Description

The `p?lanhs` function returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of an upper Hessenberg distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$.

Input Parameters

<i>norm</i>	Specifies the value to be returned by the function: = 'M' or 'm': $val = \max(\text{abs}(A_{ij}))$, largest absolute value of the matrix A . = '1' or 'O' or 'o': $val = \text{norm1}(A)$, 1-norm of the matrix A (maximum column sum), = 'I' or 'i': $val = \text{normI}(A)$, infinity norm of the matrix A (maximum row sum), = 'F', 'f', 'E' or 'e': $val = \text{normF}(A)$, Frobenius norm of the matrix A (square root of sum of squares).
<i>n</i>	(global) The number of columns in the distributed matrix $\text{sub}(A)$. When $n = 0$, <code>p?lanhs</code> is set to zero. $n \geq 0$.
<i>a</i>	(local). Pointer into the local memory to an array of size $lld\_a * LOCC(ja+n-1)$ containing the local pieces of the distributed matrix $\text{sub}(A)$.
<i>ia, ja</i>	(global) The row and column indices in the global matrix A indicating the first row and the first column of the matrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix A .
<i>work</i>	(local). Array of size $lwork$. $lwork \geq 0$ if $norm = 'M'$ or $'m'$ (not referenced),

$nq0$ if $norm = '1', 'O' \text{ or } 'o'$,
 $mp0$ if $norm = 'I' \text{ or } 'i'$,
 0 if $norm = 'F', 'f', 'E' \text{ or } 'e'$ (not referenced),
 where
 $iroffa = \text{mod}(ia-1, mb\_a)$, $icoffa = \text{mod}(ja-1, nb\_a)$,
 $iarow = \text{indxg2p}(ia, mb\_a, myrow, rsrc\_a, nprow)$,
 $iacol = \text{indxg2p}(ja, nb\_a, mycol, csrc\_a, npcrow)$,
 $mp0 = \text{numroc}(m+iroffa, mb\_a, myrow, iarow, nprow)$,
 $nq0 = \text{numroc}(n+icoffa, nb\_a, mycol, iacol, npcrow)$,
 indxg2p and numroc are ScaLAPACK tool functions; $myrow$, $mycol$, $nprow$,
 and $npcol$ can be determined by calling the function `blacs_gridinfo`.

Output Parameters

`val` The value returned by the function.

See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

p?lansy, p?lanhe

Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of a real symmetric or a complex Hermitian matrix.

Syntax

```

float pslansy (char *norm , char *uplo , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , float *work );

double pdlansy (char *norm , char *uplo , MKL_INT *n , double *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , double *work );

float pclansy (char *norm , char *uplo , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , float *work );

double pzlansy (char *norm , char *uplo , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , double *work );

float pclanhe (char *norm , char *uplo , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , float *work );

double pzlanhe (char *norm , char *uplo , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , double *work );
  
```

Description

The `p?lansy` and `p?lanhe` functions return the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$.

Input Parameters

<i>norm</i>	(global) Specifies what value is returned by the function: = 'M' or 'm': $val = \max(\text{abs}(A_{ij})),$ largest absolute value of the matrix A, it s not a matrix norm. = '1' or 'O' or 'o': $val = \text{norm1}(A),$ 1-norm of the matrix A (maximum column sum), = 'I' or 'i': $val = \text{normI}(A),$ infinity norm of the matrix A (maximum row sum), = 'F', 'f', 'E' or 'e': $val = \text{normF}(A),$ Frobenius norm of the matrix A (square root of sum of squares).
<i>uplo</i>	(global) Specifies whether the upper or lower triangular part of the symmetric matrix $\text{sub}(A)$ is to be referenced. = 'U': Upper triangular part of $\text{sub}(A)$ is referenced, = 'L': Lower triangular part of $\text{sub}(A)$ is referenced.
<i>n</i>	(global) The number of columns in the distributed matrix $\text{sub}(A)$. When $n = 0$, $p?$lansy is set to zero. $n \geq 0$.
<i>a</i>	(local). Pointer into the local memory to an array of size $lld\_a * LOCc(ja+n-1)$ containing the local pieces of the distributed matrix $\text{sub}(A)$. If $uplo = 'U'$, the leading n-by-n upper triangular part of $\text{sub}(A)$ contains the upper triangular matrix whose norm is to be computed, and the strictly lower triangular part of this matrix is not referenced. If $uplo = 'L'$, the leading n-by-n lower triangular part of $\text{sub}(A)$ contains the lower triangular matrix whose norm is to be computed, and the strictly upper triangular part of $\text{sub}(A)$ is not referenced.
<i>ia, ja</i>	(global) The row and column indices in the global matrix A indicating the first row and the first column of the matrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix A.
<i>work</i>	(local). Array of size $lwork$. $lwork \geq 0$ if $norm = 'M'$ or $'m'$ (not referenced), $2*nq0+mp0+ldw$ if $norm = '1', 'O'$ or $'o', 'I'$ or $'i'$, where ldw is given by: <pre> if(nprow$\neq$npcol) then ldw = mb_a*iceil(iceil(np0,mb_a), (lcm/nprow)) else ldw = 0 end if </pre>

0 if *norm* = 'F', 'f', 'E' or 'e' (not referenced),
 where *lcm* is the least common multiple of *nprow* and *npcol*, *lcm* =
`ilcm( nprow, npcol )` and `iceil(x,y)` is a ScaLAPACK function that
 returns ceiling (*x/y*).
`iroffa = mod(ia-1, mb_a ), icoffa = mod( ja-1, nb_a ),`
`iarow = indxg2p(ia, mb_a, myrow, rsrc_a, nprow),`
`iacol = indxg2p(ja, nb_a, mycol, csrc_a, npcol),`
`mp0 = numroc(m+iroffa, mb_a, myrow, iarow, nprow),`
`nq0 = numroc(n+icoffa, nb_a, mycol, iacol, npcol),`
ilcm, *iceil*, *indxg2p*, and *numroc* are ScaLAPACK tool functions; *myrow*,
mycol, *nprow*, and *npcol* can be determined by calling the function
`blacs_gridinfo`.

Output Parameters

val The value returned by the function.

See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

p?lantr

Returns the value of the 1-norm, Frobenius norm, infinity-norm, or the largest absolute value of any element, of a triangular matrix.

Syntax

```
float pslantr (char *norm , char *uplo , char *diag , MKL_INT *m , MKL_INT *n , float
*a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *work );

double pdlantr (char *norm , char *uplo , char *diag , MKL_INT *m , MKL_INT *n ,
double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *work );

float pclantr (char *norm , char *uplo , char *diag , MKL_INT *m , MKL_INT *n ,
MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *work );

double pzlantr (char *norm , char *uplo , char *diag , MKL_INT *m , MKL_INT *n ,
MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *work );
```

Include Files

- `mkl_scalapack.h`

Description

The `p?lantr` function returns the value of the 1-norm, or the Frobenius norm, or the infinity norm, or the element of largest absolute value of a trapezoidal or triangular distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$.

Input Parameters

norm (global) Specifies what value is returned by the function:

	= 'M' or 'm': $val = \max(\text{abs}(A_{ij})),$ largest absolute value of the matrix A, it s not a matrix norm. = '1' or 'O' or 'o': $val = \text{norm1}(A),$ 1-norm of the matrix A (maximum column sum), = 'I' or 'i': $val = \text{normI}(A),$ infinity norm of the matrix A (maximum row sum), = 'F', 'f', 'E' or 'e': $val = \text{normF}(A),$ Frobenius norm of the matrix A (square root of sum of squares).
<i>uplo</i>	(global) Specifies whether the upper or lower triangular part of the symmetric matrix $\text{sub}(A)$ is to be referenced. = 'U': Upper trapezoidal, = 'L': Lower trapezoidal. Note that $\text{sub}(A)$ is triangular instead of trapezoidal if $m = n$.
<i>diag</i>	(global) Specifies whether the distributed matrix $\text{sub}(A)$ has unit diagonal. = 'N': Non-unit diagonal. = 'U': Unit diagonal.
<i>m</i>	(global) The number of rows in the distributed matrix $\text{sub}(A)$. When $m = 0$, $p?$ lantr is set to zero. $m \geq 0$.
<i>n</i>	(global) The number of columns in the distributed matrix $\text{sub}(A)$. When $n = 0$, $p?$ lantr is set to zero. $n \geq 0$.
<i>a</i>	(local). Pointer into the local memory to an array of size $\text{lld\_a} * \text{LOCc}(ja+n-1)$ containing the local pieces of the distributed matrix $\text{sub}(A)$.
<i>ia, ja</i>	(global) The row and column indices in the global matrix A indicating the first row and the first column of the matrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) array of size $dlen_$. The array descriptor for the distributed matrix A.
<i>work</i>	(local). Array size $lwork$. $lwork \geq 0$ if $norm = 'M'$ or $'m'$ (not referenced), $nq0$ if $norm = '1', 'O'$ or $'o',$ $mp0$ if $norm = 'I'$ or $'i',$ 0 if $norm = 'F', 'f', 'E'$ or $'e'$ (not referenced),

```

irow = mod(ia-1, mb_a ), icoffa = mod( ja-1, nb_a ),
iarow = indxg2p(ia, mb_a, myrow, rsrc_a, nprow),
iacol = indxg2p(ja, nb_a, mycol, csrc_a, npcol),
mp0 = numroc(m+irow, mb_a, myrow, iarow, nprow),
nq0 = numroc(n+icoffa, nb_a, mycol, iacol, npcol),

```

indxg2p and numroc are ScaLAPACK tool functions; *myrow*, *mycol*, *nprow*, and *npcol* can be determined by calling the function `blacs_gridinfo`.

Output Parameters

<code>val</code>	The value returned by the function.

p?lapiv

Applies a permutation matrix to a general distributed matrix, resulting in row or column pivoting.

Syntax

```
void pslapiv (char *direc , char *rowcol , char *pivroc , MKL_INT *m , MKL_INT *n ,
float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *ipiv , MKL_INT *ip ,
MKL_INT *jp , MKL_INT *descip , MKL_INT *iwork );

void pdlapiv (char *direc , char *rowcol , char *pivroc , MKL_INT *m , MKL_INT *n ,
double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *ipiv , MKL_INT *ip ,
MKL_INT *jp , MKL_INT *descip , MKL_INT *iwork );

void pclapiv (char *direc , char *rowcol , char *pivroc , MKL_INT *m , MKL_INT *n ,
MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *ipiv , MKL_INT
*ip , MKL_INT *jp , MKL_INT *descip , MKL_INT *iwork );

void pzlapiv (char *direc , char *rowcol , char *pivroc , MKL_INT *m , MKL_INT *n ,
MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *ipiv ,
MKL_INT *ip , MKL_INT *jp , MKL_INT *descip , MKL_INT *iwork );
```

Include Files

- `mk1 scalapack.h`

Description

The `p2lapiv` function applies either P (permutation matrix indicated by *ipiv*) or $\text{inv}(P)$ to a general m -by- n distributed matrix $\text{sub}(A) = A(\text{ia}:\text{ia}+m-1, \text{ja}:\text{ja}+n-1)$, resulting in row or column pivoting. The pivot vector may be distributed across a process row or a column. The pivot vector should be aligned with the distributed matrix A . This function will transpose the pivot vector, if necessary.

For example, if the row pivots should be applied to the columns of $\text{sub}(A)$, pass `rowcol='C'` and `pivroc='C'`.

Input Parameters

direc (global)

Specifies in which order the permutation is applied:

= 'F' (Forward): Applies pivots forward from top of matrix. Computes $P \cdot \text{sub}(A)$.

= 'B' (Backward): Applies pivots backward from bottom of matrix. Computes $\text{inv}(P) \cdot \text{sub}(A)$.

rowcol

(global)

Specifies if the rows or columns are to be permuted:

= 'R': Rows will be permuted,

= 'C': Columns will be permuted.

pivroc

(global)

Specifies whether *ipiv* is distributed over a process row or column:

= 'R': *ipiv* is distributed over a process row,

= 'C': *ipiv* is distributed over a process column.

m

(global)

The number of rows in the distributed matrix $\text{sub}(A)$. When $m = 0$, $p?$ *lapiv* is set to zero. $m \geq 0$.

n

(global)

The number of columns in the distributed matrix $\text{sub}(A)$. When $n = 0$, $p?$ *lapiv* is set to zero. $n \geq 0$.

a

(local).

Pointer into the local memory to an array of size $lld\_a * LOCC(ja+n-1)$ containing the local pieces of the distributed matrix $\text{sub}(A)$.

ia, ja

(global)

The row and column indices in the global matrix A indicating the first row and the first column of the matrix $\text{sub}(A)$, respectively.

desca

(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix A .

ipiv

(local)

Array of size *lipiv* ;

when *rowcol*='R' or 'r':

$lipiv \geq LOCr(ia+m-1) + mb\_a$ if *pivroc*='C' or 'c',

$lipiv \geq LOCC(m + \text{mod}(jp-1, nb\_p))$ if *pivroc*='R' or 'r', and,

when *rowcol*='C' or 'c':

$lipiv \geq LOCr(n + \text{mod}(ip-1, mb\_p))$ if *pivroc*='C' or 'c',

$lipiv \geq LOCC(ja+n-1) + nb\_a$ if *pivroc*='R' or 'r'.

This array contains the pivoting information. *ipiv*(*i*) is the global row (column), local row (column) *i* was swapped with. When *rowcol*='R' or 'r' and *pivroc*='C' or 'c', or *rowcol*='C' or 'c' and *pivroc*='R' or 'r', the last piece of this array of size *mb_a* (resp. *nb_a*) is used as workspace. In those cases, this array is tied to the distributed matrix *A*.

ip, jp (global) The row and column indices in the global matrix *P* indicating the first row and the first column of the matrix sub(*P*), respectively.

descrip (global and local) array of size *dlen_*. The array descriptor for the distributed vector *ipiv*.

iwork (local).

Array of size *ldw*, where *ldw* is equal to the workspace necessary for transposition, and the storage of the transposed *ipiv*:

Let *lcm* be the least common multiple of *nprow* and *npcol*.

```
if( *rowcol == 'r' && *pivroc == 'r') {
    if( nprow == npcol ) {
        ldw = LOCr( n_p + (*jp-1)%nb_p ) + nb_p;
    } else {
        ldw = LOCr( n_p + (*jp-1)%nb_p ) +
        nb_p * ceil( ceil(LOCc(n_p)/nb_p) / (lcm/npcol) );
    }
} else if( *rowcol == 'c' && *pivroc == 'c') {
    if( nprow == npcol ) {
        ldw = LOCc( m_p + (*ip-1)%mb_p ) + mb_p;
    } else {
        ldw = LOCc( m_p + (*ip-1)%mb_p ) +
        mb_p * ceil( ceil(LOCr(m_p)/mb_p) / (lcm/nprow) );
    }
} else {
    // iwork is not referenced.
}
```

Output Parameters

a (local).

On exit, the local pieces of the permuted distributed submatrix.

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

p?laqge

Scales a general rectangular matrix, using row and column scaling factors computed by p?geequ.

Syntax

```
void pslaqge (MKL_INT *m , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , float *r , float *c , float *rowcnd , float *colcnd , float *amax , char
*equed );
```

```
void pdlaqge (MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *r , double *c , double *rowcnd , double *colcnd , double
*amax , char *equed );
```

```

void pclaqge (MKL_INT *m , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , float *r , float *c , float *rowcnd , float *colcnd , float *amax ,
char *equed );

void pzlaqge (MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *r , double *c , double *rowcnd , double *colcnd , double
*amax , char *equed );

```

Include Files

- mkl_scalapack.h

Description

The `p?laqge` function equilibrates a general m -by- n distributed matrix $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$ using the row and scaling factors in the vectors r and c computed by `p?geequ`.

Input Parameters

m	(global) The number of rows in the distributed matrix $\text{sub}(A)$. ($m \geq 0$).
n	(global) The number of columns in the distributed matrix $\text{sub}(A)$. ($n \geq 0$).
a	(local). Pointer into the local memory to an array of size $lld\_a * LOCc(ja+n-1)$. On entry, this array contains the distributed matrix $\text{sub}(A)$.
ia, ja	(global) The row and column indices in the global matrix A indicating the first row and the first column of the matrix $\text{sub}(A)$, respectively.
$desca$	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix A .
r	(local). Array of size $LOCr(m\_a)$. The row scale factors for $\text{sub}(A)$. r is aligned with the distributed matrix A , and replicated across every process column. r is tied to the distributed matrix A .
c	(local). Array of size $LOCc(n\_a)$. The row scale factors for $\text{sub}(A)$. c is aligned with the distributed matrix A , and replicated across every process column. c is tied to the distributed matrix A .
$rowcnd$	(local). The global ratio of the smallest $r[i]$ to the largest $r[i]$, $ia-1 \leq i \leq ia+m-2$.
$colcnd$	(local). The global ratio of the smallest $c[i]$ to the largest $c[i]$, $ia-1 \leq i \leq ia+n-2$.
$amax$	(global). Absolute value of largest distributed submatrix entry.

Output Parameters

<i>a</i>	(local). On exit, the equilibrated distributed matrix. See <i>equed</i> for the form of the equilibrated distributed submatrix.
<i>equed</i>	(global) Specifies the form of equilibration that was done. = 'N': No equilibration = 'R': Row equilibration, that is, sub(A) has been pre-multiplied by $\text{diag}(r[ia-1:ia+m-2])$, = 'C': column equilibration, that is, sub(A) has been post-multiplied by $\text{diag}(c[ja-1:ja+n-2])$, = 'B': Both row and column equilibration, that is, sub(A) has been replaced by $\text{diag}(r[ia-1:ia+m-2]) * \text{sub}(A) * \text{diag}(c[ja-1:ja+n-2])$.

p?laqr0

Computes the eigenvalues of a Hessenberg matrix and optionally returns the matrices from the Schur decomposition.

Syntax

```
void pslaqr0(MKL_INT* wantt, MKL_INT* wantz, MKL_INT* n, MKL_INT* ilo, MKL_INT* ihi,
float* h, MKL_INT* desch, float* wr, float* wi, MKL_INT* iloz, MKL_INT* ihiz, float*
z, MKL_INT* descz, float* work, MKL_INT* lwork, MKL_INT* iwork, MKL_INT* liwork,
MKL_INT* info, MKL_INT* reclevel);
```

```
void pdlaqr0(MKL_INT* wantt, MKL_INT* wantz, MKL_INT* n, MKL_INT* ilo, MKL_INT* ihi,
double* h, MKL_INT* desch, double* wr, double* wi, MKL_INT* iloz, MKL_INT* ihiz,
double* z, MKL_INT* descz, double* work, MKL_INT* lwork, MKL_INT* iwork, MKL_INT*
liwork, MKL_INT* info, MKL_INT* reclevel);
```

Include Files

- `mkl_scalapack.h`

Description

`p?laqr0` computes the eigenvalues of a Hessenberg matrix H and, optionally, the matrices T and Z from the Schur decomposition $H = Z^* T^* Z^T$, where T is an upper quasi-triangular matrix (the Schur form), and Z is the orthogonal matrix of Schur vectors.

Optionally Z may be postmultiplied into an input orthogonal matrix Q so that this function can give the Schur factorization of a matrix A which has been reduced to the Hessenberg form H by the orthogonal matrix Q : $A = Q * H * Q^T = (QZ) * T * (QZ)^T$.

Input Parameters

<i>wantt</i>	(global)

	Non-zero : the full Schur form T is required; Zero : only eigenvalues are required.
<i>wantz</i>	(global) Non-zero : the matrix of Schur vectors Z is required; Zero: Schur vectors are not required.
<i>n</i>	(global) The order of the Hessenberg matrix H (and Z if <i>wantz</i> is non-zero). $n \geq 0$.
<i>ilo, ihi</i>	(global) It is assumed that the matrix H is already upper triangular in rows and columns 1: <i>ilo</i> -1 and <i>ihi</i> +1: <i>n</i> . <i>ilo</i> and <i>ihi</i> are normally set by a previous call to <code>p?gebal</code> , and then passed to <code>p?gehrd</code> when the matrix output by <i>ihi</i> is reduced to Hessenberg form. Otherwise <i>ilo</i> and <i>ihi</i> should be set to 1 and <i>n</i> , respectively. If $n > 0$, then $1 \leq ilo \leq ihi \leq n$. If $n = 0$, then <i>ilo</i> = 1 and <i>ihi</i> = 0.
<i>h</i>	(global) array of size $lld\_h * LOC_c(n)$ The upper Hessenberg matrix H .
<i>desch</i>	(global and local) Array of size <i>dlen_</i> . The array descriptor for the distributed matrix H .
<i>iloz, ihiz</i>	Specify the rows of the matrix Z to which transformations must be applied if <i>wantz</i> is non-zero, $1 \leq iloz \leq ilo$; $ihi \leq ihiz \leq n$.
<i>z</i>	Array of size $lld\_z * LOC_c(n)$. If <i>wantz</i> is non-zero, contains the matrix Z . If <i>wantz</i> equals zero, <i>z</i> is not referenced.
<i>descz</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix Z .
<i>work</i>	(local workspace) array of size <i>lwork</i>
<i>lwork</i>	(local) The length of the workspace array <i>work</i> .
<i>iwork</i>	(local workspace) array of size <i>liwork</i>
<i>liwork</i>	(local) The length of the workspace array <i>iwork</i> .
<i>recllevel</i>	(local) Level of recursion. <i>recllevel</i> = 0 must hold on entry.

OUTPUT Parameters

<i>h</i>	On exit, if <i>wantt</i> is non-zero, the matrix <i>H</i> is upper quasi-triangular in rows and columns <i>ilo:ihi</i> , with 1-by-1 and 2-by-2 blocks on the main diagonal. The 2-by-2 diagonal blocks (corresponding to complex conjugate pairs of eigenvalues) are returned in standard form, with $H(i,i) = H(i+1,i+1)$ and $H(i+1,i)*H(i,i+1) < 0$. If <i>info</i> = 0 and <i>wantt</i> equals zero, the contents of <i>h</i> are unspecified on exit.
<i>wr</i> , <i>wi</i>	The real and imaginary parts, respectively, of the computed eigenvalues <i>ilo</i> to <i>ihi</i> are stored in the corresponding elements of <i>wr</i> and <i>wi</i> . If two eigenvalues are computed as a complex conjugate pair, they are stored in consecutive elements of <i>wr</i> and <i>wi</i> , say the <i>i</i> -th and (<i>i</i> +1)th, with $wi[i-1] > 0$ and $wi[i] < 0$. If <i>wantt</i> is non-zero, the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in <i>h</i> .
<i>z</i>	Updated matrix with transformations applied only to the submatrix $Z(ilo:ihi, ilo:ihi)$. If COMPZ = 'I', on exit, if <i>info</i> = 0, <i>z</i> contains the orthogonal matrix <i>Z</i> of the Schur vectors of <i>H</i> . If <i>wantz</i> is non-zero, then $Z(ilo:ihi, iloz:ihiz)$ is replaced by $Z(ilo:ihi, iloz:ihiz)*U$, when <i>U</i> is the orthogonal/unitary Schur factor of $H(ilo:ihi, ilo:ihi)$. If <i>wantz</i> equals zero, then <i>z</i> is not defined.
<i>work</i> [0]	On exit, if <i>info</i> = 0, <i>work</i> [0] returns the optimal <i>lwork</i> .
<i>iwork</i> [0]	On exit, if <i>info</i> = 0, <i>iwork</i> [0] returns the optimal <i>liwork</i> .
<i>info</i>	> 0: if <i>info</i> = <i>i</i> , then the function failed to compute all the eigenvalues. Elements 0: <i>ilo</i> -2 and <i>i</i> : <i>n</i> -1 of <i>wr</i> and <i>wi</i> contain those eigenvalues which have been successfully computed. > 0: if <i>wantt</i> equals zero, then the remaining unconverged eigenvalues are the eigenvalues of the upper Hessenberg matrix rows and columns <i>ilo</i> through <i>ihi</i> of the final output value of <i>H</i> . > 0: if <i>wantt</i> is non-zero, then (initial value of <i>H</i>)* <i>U</i> = <i>U</i> *(final value of <i>H</i>), where <i>U</i> is an orthogonal/unitary matrix. The final value of <i>H</i> is upper Hessenberg and quasi-triangular/triangular in rows and columns <i>info</i> +1 through <i>ihi</i> . > 0: if <i>wantz</i> is non-zero, then (final value of $Z(ilo:ihi, iloz:ihiz)$)=(initial value of $Z(ilo:ihi, iloz:ihiz)$)* <i>U</i> , where <i>U</i> is the orthogonal/unitary matrix in the previous expression (regardless of the value of <i>wantt</i>). > 0: if <i>wantz</i> equals zero, then <i>z</i> is not accessed.

p?laqr1

Sets a scalar multiple of the first column of the product of a 2-by-2 or 3-by-3 matrix and specified shifts.

Syntax

```
void pslaqr1(MKL_INT* wantt, MKL_INT* wantz, MKL_INT* n, MKL_INT* ilo, MKL_INT* ihi,
float* a, MKL_INT* desca, float* wr, float* wi, MKL_INT* iloz, MKL_INT* ihiz, float*
z, MKL_INT* descz, float* work, MKL_INT* lwork, MKL_INT* iwork, MKL_INT* ilwork,
MKL_INT* info);
```

```
void pdlaqr1(MKL_INT* wantt, MKL_INT* wantz, MKL_INT* n, MKL_INT* ilo, MKL_INT* ihi,
double* a, MKL_INT* desca, double* wr, double* wi, MKL_INT* iloz, MKL_INT* ihiz,
double* z, MKL_INT* descz, double* work, MKL_INT* lwork, MKL_INT* iwork, MKL_INT*
ilwork, MKL_INT* info);
```

Include Files

- mkl_scalapack.h

Description

p?laqr1 is an auxiliary function used to find the Schur decomposition and/or eigenvalues of a matrix already in Hessenberg form from columns *ilo* to *ihi*.

This is a modified version of p?lahqr from ScaLAPACK version 1.7.3. The following modifications were made:

- Workspace query functionality was added.
- Aggressive early deflation is implemented.
- Aggressive deflation (looking for two consecutive small subdiagonal elements by PSLACONSUB) is abandoned.
- The returned Schur form is now in canonical form, i.e., the returned 2-by-2 blocks really correspond to complex conjugate pairs of eigenvalues.
- For some reason, the original version of p?lahqr sometimes did not read out the converged eigenvalues correctly. This is now fixed.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

wantt

(global)

Non-zero : the full Schur form *T* is required;

Zero: only eigenvalues are required.

<i>wantz</i>	Non-zero : the matrix of Schur vectors Z is required; Zero: Schur vectors are not required.
<i>n</i>	(global) The order of the Hessenberg matrix A (and Z if <i>wantz</i> is non-zero). $n \geq 0$.
<i>ilo, ihi</i>	(global) It is assumed that the matrix A is already upper quasi-triangular in rows and columns $ihi+1:n$, and that $A(ilo, ilo-1) = 0$ (unless $ilo = 1$). $p?laqr1$ works primarily with the Hessenberg submatrix in rows and columns ilo to ihi , but applies transformations to all of H if <i>wantt</i> is non-zero. $1 \leq ilo \leq \max(1, ihi); ihi \leq n$.
<i>a</i>	(global) array of size $lld\_a * LOC_c(n)$ On entry, the upper Hessenberg matrix A .
<i>desca</i>	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix A .
<i>iloz, ihiz</i>	(global) Specify the rows of the matrix Z to which transformations must be applied if <i>wantz</i> is non-zero. $1 \leq iloz \leq ilo; ihi \leq ihiz \leq n$.
<i>z</i>	(global) array of size $lld\_z * LOC_c(n)$. If <i>wantz</i> is non-zero, on entry z must contain the current matrix Z of transformations accumulated by $p?hseqr$. If <i>wantz</i> is zero, z is not referenced.
<i>descz</i>	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix Z .
<i>work</i>	(local output) array of size <i>lwork</i>
<i>lwork</i>	(local) The size of the work array ($lwork \geq 1$). If $lwork = -1$, then a workspace query is assumed.
<i>iwork</i>	(global and local) array of size <i>ilwork</i> This holds the some of the IBLK integer arrays.
<i>ilwork</i>	(local) The size of the <i>iwork</i> array ($ilwork \geq 3$).

OUTPUT Parameters

<i>a</i>	If <i>wantt</i> is non-zero, the matrix <i>A</i> is upper quasi-triangular in rows and columns <i>ilo:ihi</i> , with any 2-by-2 or larger diagonal blocks not yet in standard form. If <i>wantte</i> equals zero, the contents of <i>a</i> are unspecified on exit.
<i>wr, wi</i>	(global replicated) array of size <i>n</i> The real and imaginary parts, respectively, of the computed eigenvalues <i>ilo</i> to <i>ihi</i> are stored in the corresponding elements of <i>wr</i> and <i>wi</i> . If two eigenvalues are computed as a complex conjugate pair, they are stored in consecutive elements of <i>wr</i> and <i>wi</i> , say the <i>i</i> -th and (<i>i</i> +1)th, with <i>wi</i> [<i>i</i> -1] > 0 and <i>wi</i> [<i>i</i>] < 0. If <i>wantt</i> is non-zero, the eigenvalues are stored in the same order as on the diagonal of the Schur form returned in <i>a</i> . <i>a</i> may be returned with larger diagonal blocks until the next release.
<i>z</i>	On exit <i>z</i> is updated; transformations are applied only to the submatrix <i>Z(ilo:ihiz,ilo:ihi)</i> . If <i>wantz</i> equals zero, <i>z</i> is not referenced.
<i>work</i> [0]	On exit, if <i>info</i> = 0, <i>work</i> [0] returns the optimal <i>lwork</i> .
<i>info</i>	(global) < 0: parameter number - <i>info</i> incorrect or inconsistent = 0: successful exit > 0: p?laqr1 failed to compute all the eigenvalues <i>ilo</i> to <i>ihi</i> in a total of 30*(<i>ihi-ilo</i> +1) iterations; if <i>info</i> = <i>i</i> , elements <i>i:ihi-1</i> of <i>wr</i> and <i>wi</i> contain those eigenvalues which have been successfully computed.

Application Notes

This algorithm is very similar to [p?ahqr](#). Unlike [p?lahqr](#), instead of sending one double shift through the largest unreduced submatrix, this algorithm sends multiple double shifts and spaces them apart so that there can be parallelism across several processor row/columns. Another critical difference is that this algorithm aggregates multiple transforms together in order to apply them in a block fashion.

Current Notes and/or Restrictions:

- This code requires the distributed block size to be square and at least six (6); unlike simpler codes like LU, this algorithm is extremely sensitive to block size. Unwise choices of too small a block size can lead to bad performance.
- This code requires *a* and *z* to be distributed identically and have identical contexts.
- This release currently does not have a function for resolving the Schur blocks into regular 2x2 form after this code is completed. Because of this, a significant performance impact is required while the deflation is done by sometimes a single column of processors.
- This code does not currently block the initial transforms so that none of the rows or columns for any bulge are completed until all are started. To offset pipeline start-up it is recommended that at least 2*LCM(NPROW,NPCOL) bulges are used (if possible)
- The maximum number of bulges currently supported is fixed at 32. In future versions this will be limited only by the incoming *work* array.
- The matrix *A* must be in upper Hessenberg form. If elements below the subdiagonal are nonzero, the resulting transforms may be nonsimilar. This is also true with the LAPACK function.
- For this release, it is assumed *rsrc_*=*csrc_*=0

- Currently, all the eigenvalues are distributed to all the nodes. Future releases will probably distribute the eigenvalues by the column partitioning.
- The internals of this function are subject to change.

p?laqr2

Performs the orthogonal/unitary similarity transformation of a Hessenberg matrix to detect and deflate fully converged eigenvalues from a trailing principal submatrix (aggressive early deflation).

Syntax

```
void pslaqr2(MKL_INT* wantt, MKL_INT* wantz, MKL_INT* n, MKL_INT* ktop, MKL_INT* kbot,
MKL_INT* nw, float* a, MKL_INT* desca, MKL_INT* iloz, MKL_INT* ihiz, float* z,
MKL_INT* descz, MKL_INT* ns, MKL_INT* nd, float* sr, float* si, float* t, MKL_INT*
ldt, float* v, MKL_INT* ldv, float* wr, float* wi, float* work, MKL_INT* lwork);

void pdlaqr2(MKL_INT* wantt, MKL_INT* wantz, MKL_INT* n, MKL_INT* ktop, MKL_INT* kbot,
MKL_INT* nw, double* a, MKL_INT* desca, MKL_INT* iloz, MKL_INT* ihiz, double* z,
MKL_INT* descz, MKL_INT* ns, MKL_INT* nd, double* sr, double* si, double* t, MKL_INT*
ldt, double* v, MKL_INT* ldv, double* wr, double* wi, double* work, MKL_INT* lwork);
```

Include Files

- `mkl_scalapack.h`

Description

`p?laqr2` accepts as input an upper Hessenberg matrix *A* and performs an orthogonal similarity transformation designed to detect and deflate fully converged eigenvalues from a trailing principal submatrix. On output *Ais* is overwritten by a new Hessenberg matrix that is a perturbation of an orthogonal similarity transformation of *A*. It is to be hoped that the final version of *A* has many zero subdiagonal entries.

This function handles small deflation windows which is affordable by one processor. Normally, it is called by `p?laqr1`. All the inputs are assumed to be valid without checking.

Optimization Notice

Notice revision #20110804

Input Parameters

wantt

(global)

If *wantt* is non-zero, then the Hessenberg matrix *A* is fully updated so that the quasi-triangular Schur factor may be computed (in cooperation with the calling function).

	If <i>wantt</i> equals zero, then only enough of <i>A</i> is updated to preserve the eigenvalues.
<i>wantz</i>	(global) If <i>wantz</i> is non-zero, then the orthogonal matrix <i>Z</i> is updated so that the orthogonal Schur factor may be computed (in cooperation with the calling function). If <i>wantz</i> equals zero, then <i>z</i> is not referenced.
<i>n</i>	(global) The order of the matrix <i>A</i> and (if <i>wantz</i> is non-zero) the order of the orthogonal matrix <i>Z</i>.
<i>ktop, kbot</i>	(global) It is assumed without a check that either $kbot = n$ or $A(kbot+1, kbot)=0$. <i>kbot</i> and <i>ktop</i> together determine an isolated block along the diagonal of the Hessenberg matrix. However, $A(ktop, ktop-1)=0$ is not essentially necessary if <i>wantt</i> is non-zero .
<i>nw</i>	(global) Deflation window size. $1 \leq nw \leq (kbot-ktop+1)$. Normally $nw \geq 3$ if <i>p?laqr2</i> is called by <i>p?laqr1</i>.
<i>a</i>	(local) array of size $lld\_a * LOC_c(n)$ The initial <i>n</i>-by-<i>n</i> section of <i>a</i> stores the Hessenberg matrix undergoing aggressive early deflation.
<i>desca</i>	(global and local) array of size <i>dlen_</i>. The array descriptor for the distributed matrix <i>A</i>.
<i>iloz, ihiz</i>	(global) Specify the rows of the matrix <i>Z</i> to which transformations must be applied if <i>wantz</i> is non-zero. $1 \leq iloz \leq ihiz \leq n$.
<i>z</i>	Array of size $lld\_z * LOC_c(n)$ If <i>wantz</i> is non-zero, then on output, the orthogonal similarity transformation mentioned above has been accumulated into the matrix <i>Z</i>(<i>iloz:ihiz</i>, <i>kbot:ktop</i>), stored in <i>z</i>, from the right. If <i>wantz</i> is zero, then <i>z</i> is unreferenced.
<i>descz</i>	(global and local) array of size <i>dlen_</i>. The array descriptor for the distributed matrix <i>Z</i>.
<i>t</i>	(local workspace) array of size $ldt * nw$.
<i>ldt</i>	(local) The leading dimension of the array <i>t</i>. $ldt \geq nw$.

<i>v</i>	(local workspace) array of size $ldv * nw$.
<i>ldv</i>	(local) The leading dimension of the array <i>v</i> . $ldv \geq nw$.
<i>wr, wi</i>	(local workspace) array of size <i>kbot</i> .
<i>work</i>	(local workspace) array of size <i>lwork</i> .
<i>lwork</i>	(local) <i>work(lwork)</i> is a local array and <i>lwork</i> is assumed big enough so that $lwork \geq nw * nw$.

OUTPUT Parameters

<i>a</i>	On output <i>a</i> has been transformed by an orthogonal similarity transformation, perturbed, and returned to Hessenberg form that (it is to be hoped) has some zero subdiagonal entries.
<i>z</i>	
<i>ns</i>	(global) The number of unconverged (that is, approximate) eigenvalues returned in <i>sr</i> and <i>si</i> that may be used as shifts by the calling function.
<i>nd</i>	(global) The number of converged eigenvalues uncovered by this function.
<i>sr, si</i>	(global) array of size <i>kbot</i> On output, the real and imaginary parts of approximate eigenvalues that may be used for shifts are stored in <i>sr</i> [<i>kbot-nd-ns</i>] through <i>sr</i> [<i>kbot-nd-1</i>] and <i>si</i> [<i>kbot-nd-ns</i>] through <i>si</i> [<i>kbot-nd-1</i>], respectively. On processor #0, the real and imaginary parts of converged eigenvalues are stored in <i>sr</i> [<i>kbot-nd</i>] through <i>sr</i> [<i>kbot-1</i>] and <i>si</i> [<i>kbot-nd</i>] through <i>si</i> [<i>kbot-1</i>], respectively. On other processors, these entries are set to zero.

descw, double* work, MKL_INT* lwork, MKL_INT* iwork, MKL_INT* liwork, MKL_INT*
recllevel);
```

Include Files

- mkl_scalapack.h

Description

This function accepts as input an upper Hessenberg matrix H and performs an orthogonal similarity transformation designed to detect and deflate fully converged eigenvalues from a trailing principal submatrix. On output H is overwritten by a new Hessenberg matrix that is a perturbation of an orthogonal similarity transformation of H . It is to be hoped that the final version of H has many zero subdiagonal entries.

Input Parameters

<i>wantt</i>	(global) If <i>wantt</i> is non-zero, then the Hessenberg matrix H is fully updated so that the quasi-triangular Schur factor may be computed (in cooperation with the calling function). If <i>wantt</i> equals zero, then only enough of H is updated to preserve the eigenvalues.
<i>wantz</i>	(global) If <i>wantz</i> is non-zero, then the orthogonal matrix Z is updated so that the orthogonal Schur factor may be computed (in cooperation with the calling function). If <i>wantz</i> equals zero, then z is not referenced.
<i>n</i>	(global) The order of the matrix H and (if <i>wantz</i> is non-zero), the order of the orthogonal matrix Z .
<i>ktop</i>	(global) It is assumed that either $ktop = 1$ or $H(ktop,ktop-1)=0$. <i>kbot</i> and <i>ktop</i> together determine an isolated block along the diagonal of the Hessenberg matrix.
<i>kbot</i>	(global) It is assumed without a check that either $kbot = n$ or $H(kbot+1,kbot)=0$. <i>kbot</i> and <i>ktop</i> together determine an isolated block along the diagonal of the Hessenberg matrix.
<i>nw</i>	(global) Deflation window size. $1 \leq nw \leq (kbot-ktop+1)$.
<i>h</i>	(local) array of size $lld_h * LOC_c(n)$

	The initial n -by- n section of H stores the Hessenberg matrix undergoing aggressive early deflation.
<i>desch</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix H .
<i>iloz, ihiz</i>	(global) Specify the rows of the matrix Z to which transformations must be applied if <i>wantz</i> is non-zero. $1 \leq iloz \leq ihiz \leq n$.
<i>z</i>	Array of size $lld\_z * LOC_c(n)$ If <i>wantz</i> is non-zero, then on output, the orthogonal similarity transformation mentioned above has been accumulated into the matrix $Z(iloz:ihiz, kbot:ktop)$ from the right. If <i>wantz</i> is zero, then <i>z</i> is unreferenced.
<i>descz</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix Z .
<i>v</i>	(global workspace) array of size $lld\_v * LOC_c(nw)$ An nw -by- nw distributed work array.
<i>descv</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix V .
<i>nh</i>	The number of columns of t . $nh \geq nw$.
<i>t</i>	(global workspace) array of size $lld\_t * LOC_c(nh)$
<i>desct</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix T .
<i>nv</i>	(global) The number of rows of work array wv available for workspace. $nv \geq nw$.
<i>wv</i>	(global workspace) array of size $lld\_w * LOC_c(nw)$
<i>descw</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix wv .
<i>work</i>	(local workspace) array of size <i>lwork</i> .
<i>lwork</i>	(local) The size of the work array <i>work</i> ($lwork \geq 1$). $lwork = 2 * nw$ suffices, but greater efficiency may result from larger values of <i>lwork</i> . If $lwork = -1$, then a workspace query is assumed; <code>p?laqr3</code> only estimates the optimal workspace size for the given values of n , nw , $ktop$ and $kbot$. The estimate is returned in <i>work</i> [0]. No error message related to <i>lwork</i> is issued by <code>xerbla</code> . Neither h nor z are accessed.

iwork (local workspace) array of size *liwork*

liwork (local)

The length of the workspace array *iwork* (*liwork*≥1).

If *liwork*=-1, then a workspace query is assumed.

OUTPUT Parameters

h On output *h* has been transformed by an orthogonal similarity transformation, perturbed, and the returned to Hessenberg form that (it is to be hoped) has some zero subdiagonal entries.

z IF *wantz* is non-zero, then on output, the orthogonal similarity transformation mentioned above has been accumulated into the matrix *Z*(*iloz:ihiz*,*kbot:ktop*) from the right.

If *wantz* is zero, then *z* is unreferenced.

ns (global)

The number of unconverged (that is, approximate) eigenvalues returned in *sr* and *si* that may be used as shifts by the calling function.

nd (global)

The number of converged eigenvalues uncovered by this function.

sr, si (global) array of size *kbot*. The real and imaginary parts of approximate eigenvalues that may be used for shifts are stored in *sr*[*kbot-nd-ns*] through *sr*[*kbot-nd-1*] and *si*[*kbot-nd-ns*] through *si*[*kbot-nd-1*], respectively. The real and imaginary parts of converged eigenvalues are stored in *sr*[*kbot-nd*] through *sr*[*kbot-1*] and *si*[*kbot-nd*] through *si*[*kbot-1*], respectively.

work[0] On exit, if *info* = 0, *work*[0] returns the optimal *lwork*

iwork[0] On exit, if *info* = 0, *iwork*[0] returns the optimal *liwork*

p?laqr5

Performs a single small-bulge multi-shift QR sweep.

Syntax

```
void pslaqr5(MKL_INT* wantt, MKL_INT* wantz, MKL_INT* kacc22, MKL_INT* n, MKL_INT*
ktop, MKL_INT* kbot, MKL_INT* nshfts, float* sr, float* si, float* h, MKL_INT*
desch, MKL_INT* iloz, MKL_INT* ihiz, float* z, MKL_INT* descz, float* work, MKL_INT* lwork,
MKL_INT* iwork, MKL_INT* liwork);

void pdlaqr5(MKL_INT* wantt, MKL_INT* wantz, MKL_INT* kacc22, MKL_INT* n, MKL_INT*
ktop, MKL_INT* kbot, MKL_INT* nshfts, double* sr, double* si, double* h, MKL_INT*
desch, MKL_INT* iloz, MKL_INT* ihiz, double* z, MKL_INT* descz, double* work, MKL_INT*
lwork, MKL_INT* iwork, MKL_INT* liwork);
```

Include Files

- `mkl_scalapack.h`

Description

This auxiliary function called by `p?laqr0` performs a single small-bulge multi-shift QR sweep by chasing separated groups of bulges along the main block diagonal of a Hessenberg matrix H .

Input Parameters

<code>wantt</code>	(global) scalar <code>wantt</code> is non-zero if the quasi-triangular Schur factor is being computed. <code>wantt</code> is set to zero otherwise.
<code>wantz</code>	(global) scalar <code>wantz</code> is non-zero if the orthogonal Schur factor is being computed. <code>wantz</code> is set to zero otherwise.
<code>kacc22</code>	(global) Value 0, 1, or 2. Specifies the computation mode of far-from-diagonal orthogonal updates. = 0: <code>p?laqr5</code> does not accumulate reflections and does not use matrix-matrix multiply to update far-from-diagonal matrix entries. = 1: <code>p?laqr5</code> accumulates reflections and uses matrix-matrix multiply to update the far-from-diagonal matrix entries. = 2: <code>p?laqr5</code> accumulates reflections, uses matrix-matrix multiply to update the far-from-diagonal matrix entries, and takes advantage of 2-by-2 block structure during matrix multiplies.
<code>n</code>	(global) scalar The order of the Hessenberg matrix H and, if <code>wantz</code> is non-zero, the order of the orthogonal matrix Z .
<code>ktop, kbot</code>	(global) scalar These are the first and last rows and columns of an isolated diagonal block upon which the QR sweep is to be applied. It is assumed without a check that either <code>ktop = 1</code> or $H(ktop, ktop-1) = 0$ and either <code>kbot = n</code> or $H(kbot+1, kbot) = 0$.
<code>nshfts</code>	(global) scalar <code>nshfts</code> gives the number of simultaneous shifts. <code>nshfts</code> must be positive and even.
<code>sr, si</code>	(global) Array of size <code>nshfts</code> <code>sr</code> contains the real parts and <code>si</code> contains the imaginary parts of the <code>nshfts</code> shifts of origin that define the multi-shift QR sweep.
<code>h</code>	(local) Array of size <code>lld_h * LOC_c(n)</code> On input <code>h</code> contains a Hessenberg matrix H .
<code>desch</code>	(global and local)

	array of size $dlen\_$.
	The array descriptor for the distributed matrix H .
$iloz, ihiz$	(global) Specify the rows of the matrix Z to which transformations must be applied if $wantzis$ is non-zero. $1 \leq iloz \leq ihiz \leq n$
z	(local) array of size $lld\_z * LOC_c(n)$ If $wantzis$ is non-zero, then the QR Sweep orthogonal similarity transformation is accumulated into the matrix $Z(iloz:ihiz,kbot:ktop)$ from the right. If $wantzequals$ zero, then z is unreferenced.
$descz$	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix Z .
$work$	(local workspace) array of size $lwork$
$lwork$	(local) The size of the $work$ array ($lwork \geq 1$). If $lwork = -1$, then a workspace query is assumed.
$iwork$	(local workspace) array of size $liwork$
$liwork$	(local) The size of the $iwork$ array ($liwork \geq 1$). If $liwork = -1$, then a workspace query is assumed.

Output Parameters

h	A multi-shift QR sweep with shifts $sr(j) + i * si(j)$ is applied to the isolated diagonal block in rows and columns $ktop$ through $kbot$ of the matrix H .
z	If $wantzis$ is non-zero, z is updated with transformations applied only to the submatrix $Z(iloz:ihiz,kbot:ktop)$.
$work[0]$	On exit, if $info = 0$, $work[0]$ returns the optimal $lwork$.
$iwork[0]$	On exit, if $info = 0$, $iwork[0]$ returns the optimal $liwork$.

- mkl_scalapack.h

Description

The `p?laqsy` function equilibrates a symmetric distributed matrix $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$ using the scaling factors in the vectors `sr` and `sc`. The scaling factors are computed by `p?poequ`.

Input Parameters

<code>uplo</code>	(global) Specifies the upper or lower triangular part of the symmetric distributed matrix $\text{sub}(A)$ is to be referenced: = 'U': Upper triangular part; = 'L': Lower triangular part.
<code>n</code>	(global) The order of the distributed matrix $\text{sub}(A)$. $n \geq 0$.
<code>a</code>	(local). Pointer into the local memory to an array of size $lld\_a * LOCc(ja+n-1)$. On entry, this array contains the local pieces of the distributed matrix $\text{sub}(A)$. On entry, the local pieces of the distributed symmetric matrix $\text{sub}(A)$. If <code>uplo</code> = 'U', the leading n -by- n upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and the strictly lower triangular part of $\text{sub}(A)$ is not referenced. If <code>uplo</code> = 'L', the leading n -by- n lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the matrix, and the strictly upper triangular part of $\text{sub}(A)$ is not referenced.
<code>ia, ja</code>	(global) The row and column indices in the global matrix A indicating the first row and the first column of the matrix $\text{sub}(A)$, respectively.
<code>desca</code>	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix A .
<code>sr</code>	(local) Array of size $LOCr(m\_a)$. The scale factors for the matrix $A(ia:ia+m-1, ja:ja+n-1)$. <code>sr</code> is aligned with the distributed matrix A , and replicated across every process column. <code>sr</code> is tied to the distributed matrix A .

<i>sc</i>	(local) Array of size $LOCc(m_a)$. The scale factors for the matrix A ($ia:ia+m-1$, $ja:ja+n-1$). <i>sc</i> is aligned with the distributed matrix A , and replicated across every process column. <i>sc</i> is tied to the distributed matrix A .
<i>scond</i>	(global). Ratio of the smallest $sr[j]$ (respectively $sc[j]$) to the largest $sr[j]$ (respectively $sc[j]$), with $ia-1 \leq j < ia+n-1$ and $ja-1 \leq j < ja+n-1$.
<i>amax</i>	(global). Absolute value of largest distributed submatrix entry.

Output Parameters

<i>a</i>	On exit, if <i>equed</i> = 'Y', the equilibrated matrix: $\text{diag}(sr_{ia}, \dots, sr_{ia+n-1}) * \text{sub}(A) * \text{diag}(sc_{ja}, \dots, sc_{ja+n-1})$.
<i>equed</i>	(global). Specifies whether or not equilibration was done. = 'N': No equilibration. = 'Y': Equilibration was done, that is, $\text{sub}(A)$ has been replaced by: $\text{diag}(sr_{ia}, \dots, sr_{ia+n-1}) * \text{sub}(A) * \text{diag}(sc_{ja}, \dots, sc_{ja+n-1})$.

p?lared1d

Redistributes an array assuming that the input array, bycol, is distributed across rows and that all process columns contain the same copy of bycol.

Syntax

```
void pslared1d (MKL_INT *n , MKL_INT *ia , MKL_INT *ja , MKL_INT *desc , float *bycol ,
float *byall , float *work , MKL_INT *lwork );
```

```
void pdlared1d (MKL_INT *n , MKL_INT *ia , MKL_INT *ja , MKL_INT *desc , double
*bycol , double *byall , double *work , MKL_INT *lwork );
```

Include Files

- mkl_scalapack.h

Description

The p?lared1d function redistributes a 1D array. It assumes that the input array *bycol* is distributed across rows and that all process column contain the same copy of *bycol*. The output array *byall* is identical on all processes and contains the entire array.

Input Parameters

np = Number of local rows in *bycol*()

<i>n</i>	(global) The number of elements to be redistributed. $n \geq 0$.
<i>ia, ja</i>	(global) <i>ia, ja</i> must be equal to 1.
<i>desc</i>	(local) array of size 9. A 2D array descriptor, which describes <i>bycol</i> .
<i>bycol</i>	(local). Distributed block cyclic array of global size <i>n</i> and of local size <i>np</i> . <i>bycol</i> is distributed across the process rows. All process columns are assumed to contain the same value.
<i>work</i>	(local). size <i>lwork</i> . Used to hold the buffers sent from one process to another.
<i>lwork</i>	(local) The size of the <i>work</i> array. $lwork \geq \text{numroc}(n, \text{desc}[nb\_], 0, 0, npcol)$.

Output Parameters

<i>byall</i>	(global). Global size <i>n</i> , local size <i>n</i> . <i>byall</i> is exactly duplicated on all processes. It contains the same values as <i>bycol</i> , but it is replicated across all processes rather than being distributed.

See Also

Description

The p?lared2d function redistributes a 1D array. It assumes that the input array *byrow* is distributed across columns and that all process rows contain the same copy of *byrow*. The output array *byall* will be identical on all processes and will contain the entire array.

Input Parameters

np = Number of local rows in *byrow*()

<i>n</i>	(global) The number of elements to be redistributed. $n \geq 0$.
<i>ia, ja</i>	(global) <i>ia, ja</i> must be equal to 1.
<i>desc</i>	(local) array of size <i>dlen_</i> . A 2D array descriptor, which describes <i>byrow</i> .
<i>byrow</i>	(local). Distributed block cyclic array of global size <i>n</i> and of local size <i>np</i> . <i>byrow</i> is distributed across the process columns. All process rows are assumed to contain the same value.
<i>work</i>	(local). size <i>lwork</i> . Used to hold the buffers sent from one process to another.
<i>lwork</i>	(local) The size of the <i>work</i> array. $lwork \geq \text{numroc}(n, \text{desc}[nb\_], 0, 0, npcol)$.

Output Parameters

<i>byall</i>	(global). Global size <i>n</i> , local size <i>n</i> . <i>byall</i> is exactly duplicated on all processes. It contains the same values as <i>byrow</i> , but it is replicated across all processes rather than being distributed.

```

Include Files

- mkl_scalapack.h

Description

The `p?larff` function applies a real/complex elementary reflector Q (or Q^T) to a real/complex m -by- n distributed matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$, from either the left or the right. Q is represented in the form

$$Q = I - \tau v v',$$

where τ is a real/complex scalar and v is a real/complex vector.

If $\tau = 0$, then Q is taken to be the unit matrix.

Input Parameters

<i>side</i>	(global). = 'L': form $Q * \text{sub}(C)$, = 'R': form $\text{sub}(C) * Q$, $Q = Q^T$.
<i>m</i>	(global) The number of rows in the distributed submatrix $\text{sub}(A)$. ($m \geq 0$).
<i>n</i>	(global) The number of columns in the distributed submatrix $\text{sub}(A)$. ($n \geq 0$).
<i>v</i>	(local). Pointer into the local memory to an array of size $lld_v * LOCc(n_v)$, containing the local pieces of the global distributed matrix V representing the Householder transformation Q , $V(iv:iv+m-1, jv)$ if $side = 'L'$ and $incv = 1$, $V(iv, jv:jv+m-1)$ if $side = 'L'$ and $incv = m_v$, $V(iv:iv+n-1, jv)$ if $side = 'R'$ and $incv = 1$, $V(iv, jv:jv+n-1)$ if $side = 'R'$ and $incv = m_v$. The array v is the representation of Q . v is not used if $\tau = 0$.
<i>iv, jv</i>	(global) The row and column indices in the global matrix V indicating the first row and the first column of the matrix $\text{sub}(V)$, respectively.
<i>descv</i>	(global and local) array of size $dlen_$. The array descriptor for the distributed matrix V .
<i>incv</i>	(global) The global increment for the elements of V . Only two values of $incv$ are supported in this version, namely 1 and m_v . <i>incv</i> must not be zero.
<i>tau</i>	(local). Array of size $LOCc(jv)$ if $incv = 1$, and $LOCr(iv)$ otherwise. This array contains the Householder scalars related to the Householder vectors. <i>tau</i> is tied to the distributed matrix V .
<i>c</i>	(local).

Pointer into the local memory to an array of size $lld\_c * LOCC(jc+n-1)$, containing the local pieces of $sub(C)$.

ic, jc

(global)

The row and column indices in the global matrix C indicating the first row and the first column of the matrix $sub(C)$, respectively.

desc

(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix C .

work

(local).

Array of size $lwork$.

If $incv = 1$,

if $side = 'L'$,

if $ivcol = iccol$,

$lwork \geq nqc0$

else

$lwork \geq mpc0 + \max(1, nqc0)$

end if

else if $side = 'R'$,

$lwork \geq nqc0 + \max(\max(1, mpc0), \text{numroc}(\text{numroc}(n +$
 $icoffc, nb\_v, 0, 0, npcol), nb\_v, 0, 0, lcmq))$

end if

else if $incv = m\_v$,

if $side = 'L'$,

$lwork \geq mpc0 + \max(\max(1, nqc0), \text{numroc}(\text{numroc}(m + iroffc, mb\_v, 0, 0, nprow), mb\_v, 0, 0, lcmq))$

else if $side = 'R'$,

if $ivrow = icrow$,

$lwork \geq mpc0$

else

$lwork \geq nqc0 + \max(1, mpc0)$

end if

end if

end if,

where lcm is the least common multiple of $nprow$ and $npcol$ and $lcm = \text{ilcm}(nprow, npcol)$, $lcmp = lcm/nprow$, $lcmq = lcm/npcol$,

Description

The `p?larfb` function applies a real/complex block reflector Q or its transpose Q^T /conjugate transpose Q^H to a real/complex distributed m -by- n matrix `sub(C) = C(ic:ic+m-1, jc:jc+n-1)` from the left or the right.

Input Parameters

`side` (global)
if `side = 'L'`: apply Q or Q^T for real flavors (Q^H for complex flavors) from the Left;

	if <i>side</i> = 'R': apply Q or Q^T for real flavors (Q^H for complex flavors) from the Right.
<i>trans</i>	(global) if <i>trans</i> = 'N': no transpose, apply Q ; for real flavors, if <i>trans</i> ='T': transpose, apply Q^T for complex flavors, if <i>trans</i> = 'C': conjugate transpose, apply Q^H ;
<i>direct</i>	(global) Indicates how Q is formed from a product of elementary reflectors. if <i>direct</i> = 'F': $Q = H(1) * H(2) * \dots * H(k)$ (Forward) if <i>direct</i> = 'B': $Q = H(k) * \dots * H(2) * H(1)$ (Backward)
<i>storev</i>	(global) Indicates how the vectors that define the elementary reflectors are stored: if <i>storev</i> = 'C': Columnwise if <i>storev</i> = 'R': Rowwise.
<i>m</i>	(global) The number of rows in the distributed matrix sub(C). ($m \geq 0$).
<i>n</i>	(global) The number of columns in the distributed matrix sub(C). ($n \geq 0$).
<i>k</i>	(global) The order of the matrix T .
<i>v</i>	(local). Pointer into the local memory to an array of size $lld\_v * LOCC(jv+k-1)$ if <i>storev</i> = 'C', $lld\_v * LOCC(jv+m-1)$ if <i>storev</i> = 'R' and <i>side</i> = 'L', $lld\_v * LOCC(jv+n-1)$ if <i>storev</i> = 'R' and <i>side</i> = 'R'. It contains the local pieces of the distributed vectors V representing the Householder transformation. if <i>storev</i> = 'C' and <i>side</i> = 'L', $lld\_v \geq \max(1, LOCr(iv+m-1))$; if <i>storev</i> = 'C' and <i>side</i> = 'R', $lld\_v \geq \max(1, LOCr(iv+n-1))$; if <i>storev</i> = 'R', $lld\_v \geq LOCr(jv+k-1)$.
<i>iv, jv</i>	(global) The row and column indices in the global matrix V indicating the first row and the first column of the matrix sub(V), respectively.
<i>descv</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix V .
<i>c</i>	(local).

Pointer into the local memory to an array of size $lld\_c * LOCc(jc+n-1)$, containing the local pieces of sub(C).

ic, jc

(global) The row and column indices in the global matrix C indicating the first row and the first column of the matrix sub(C), respectively.

desc

(global and local) array of size *dlen_*. The array descriptor for the distributed matrix C.

work

(local).

Workspace array of size *lwork*.

If *storev* = 'C',

if *side* = 'L',

$lwork \geq (nqc0 + mpc0) * k$

else if *side* = 'R',

$lwork \geq (nqc0 + \max(npv0 + \text{numroc}(\text{numroc}(n + \text{icoffc}, nb\_v, 0, 0, npc0), nb\_v, 0, 0, lcmq), mpc0)) * k$

Description

The p?larfg function generates a real/complex elementary reflector H of order n , such that

$$H * \text{sub}(X) = H * \begin{pmatrix} x(iax, jax) \\ x \end{pmatrix} = \begin{pmatrix} alpha \\ 0 \end{pmatrix}, H^H * H = I,$$

where $alpha$ is a scalar (a real scalar - for complex flavors), and $\text{sub}(X)$ is an $(n-1)$ -element real/complex distributed vector $X(ix:ix+n-2, jx)$ if $incx = 1$ and $X(ix, jx:jx+n-2)$ if $incx = m_x$. H is represented in the form

$$H = I - tau * \begin{pmatrix} 1 \\ v \end{pmatrix} * (1 \ v')$$

where tau is a real/complex scalar and v is a real/complex $(n-1)$ -element vector. Note that H is not Hermitian.

If the elements of $\text{sub}(X)$ are all zero (and $X(iax, jax)$ is real for complex flavors), then $tau = 0$ and H is taken to be the unit matrix.

Otherwise $1 \leq \text{real}(tau) \leq 2$ and $\text{abs}(tau-1) \leq 1$.

Input Parameters

n	(global) The global order of the elementary reflector. $n \geq 0$.
iax, jax	(global)

	The global row and column indices of $X(iax, jax)$ in the global matrix X .
x	(local). Pointer into the local memory to an array of size $lld\_x * LOCc(n\_x)$. This array contains the local pieces of the distributed vector $sub(X)$. Before entry, the incremented array $sub(X)$ must contain vector x .
ix, jx	(global) The row and column indices in the global matrix X indicating the first row and the first column of $sub(X)$, respectively.
$descx$	(global and local) Array of size $dlen\_$. The array descriptor for the distributed matrix X .
$incx$	(global) The global increment for the elements of x . Only two values of $incx$ are supported in this version, namely 1 and m_x . $incx$ must not be zero.

Output Parameters

$alpha$	(local) On exit, $alpha$ is computed in the process scope having the vector $sub(X)$.
x	(local). On exit, it is overwritten with the vector v .
tau	(local). Array of size $LOCc(jx)$ if $incx = 1$, and $LOCr(ix)$ otherwise. This array contains the Householder scalars related to the Householder vectors. tau is tied to the distributed matrix X .

p?larft

Forms the triangular vector T of a block reflector $H=I-V*T*V^H$.

Syntax

```
void pslarft (char *direct , char *storev , MKL_INT *n , MKL_INT *k , float *v ,
MKL_INT *iv , MKL_INT *jv , MKL_INT *descv , float *tau , float *t , float *work );

void pdlarft (char *direct , char *storev , MKL_INT *n , MKL_INT *k , double *v ,
MKL_INT *iv , MKL_INT *jv , MKL_INT *descv , double *tau , double *t , double *work );

void pclarft (char *direct , char *storev , MKL_INT *n , MKL_INT *k , MKL_Complex8 *v ,
MKL_INT *iv , MKL_INT *jv , MKL_INT *descv , MKL_Complex8 *tau , MKL_Complex8 *t ,
MKL_Complex8 *work );

void pzlarft (char *direct , char *storev , MKL_INT *n , MKL_INT *k , MKL_Complex16
*v , MKL_INT *iv , MKL_INT *jv , MKL_INT *descv , MKL_Complex16 *tau , MKL_Complex16
*t , MKL_Complex16 *work );
```

Include Files

- mkl_scalapack.h

Description

The `p?larft` function forms the triangular factor T of a real/complex block reflector H of order n , which is defined as a product of k elementary reflectors.

If $direct = 'F'$, $H = H(1)*H(2) \dots *H(k)$, and T is upper triangular;

If $direct = 'B'$, $H = H(k)* \dots *H(2)*H(1)$, and T is lower triangular.

If $storev = 'C'$, the vector which defines the elementary reflector $H(i)$ is stored in the i -th column of the distributed matrix V , and

$$H = I - V * T * V'$$

If $storev = 'R'$, the vector which defines the elementary reflector $H(i)$ is stored in the i -th row of the distributed matrix V , and

$$H = I - V' * T * V.$$

Input Parameters

<i>direct</i>	(global) Specifies the order in which the elementary reflectors are multiplied to form the block reflector: if $direct = 'F'$: $H = H(1)*H(2)* \dots *H(k)$ (forward) if $direct = 'B'$: $H = H(k)* \dots *H(2)*H(1)$ (backward).
<i>storev</i>	(global) Specifies how the vectors that define the elementary reflectors are stored (See <i>Application Notes</i> below): if $storev = 'C'$: columnwise; if $storev = 'R'$: rowwise.
<i>n</i>	(global) The order of the block reflector H . $n \geq 0$.
<i>k</i>	(global) The order of the triangular factor T , is equal to the number of elementary reflectors. $1 \leq k \leq mb\_v$ ($= nb\_v$).
<i>v</i>	Pointer into the local memory to an array of local size $LOCr(iv+n-1) * LOCc(jv+k-1)$ if $storev = 'C'$, and $LOCr(iv+k-1) * LOCc(jv+n-1)$ if $storev = 'R'$. The distributed matrix V contains the Householder vectors. (See <i>Application Notes</i> below).
<i>iv, jv</i>	(global)

The row and column indices in the global matrix V indicating the first row and the first column of the matrix $\text{sub}(V)$, respectively.

<i>descv</i>	(local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix V .
<i>tau</i>	(local) Array of size $\text{LOCr}(iv+k-1)$ if $\text{incv} = m\_v$, and $\text{LOCc}(jv+k-1)$ otherwise. This array contains the Householder scalars related to the Householder vectors. <i>tau</i> is tied to the distributed matrix V .
<i>work</i>	(local). Workspace array of size $k*(k-1)/2$.

Output Parameters

<i>v</i>	
<i>t</i>	(local) Array of size $nb\_v * nb\_v$ if $\text{storev} = 'C'$, and $mb\_v * mb\_v$ otherwise. It contains the k -by- k triangular factor of the block reflector associated with v . If $\text{direct} = 'F'$, t is upper triangular; if $\text{direct} = 'B'$, t is lower triangular.

Application Notes

The shape of the matrix V and the storage of the vectors that define the $H(i)$ is best illustrated by the following example with $n = 5$ and $k = 3$. The elements equal to 1 are not stored; the corresponding array elements are modified but restored on exit. The rest of the array is not used.

```

=====
| 1 | 1 | 1 | 1 | 1 |
| 1 | 1 | 1 | 1 | 1 |
| 1 | 1 | 1 | 1 | 1 |
| 1 | 1 | 1 | 1 | 1 |
| 1 | 1 | 1 | 1 | 1 |
=====

```

direct = 'B' and *storev* = 'C'

$$V(iv : iv + n - 1, jv : jv + k - 1) = \begin{bmatrix} v1 & v2v & v3 \\ v1 & v2 & v3 \\ 1 & v2 & v3 \\ & 1 & v3 \\ & & 1 \end{bmatrix}$$

direct = 'B' and *storev* = 'R'

$$V(iv : iv + k - 1, jv : jv + n - 1) = \begin{bmatrix} v1 & v1 & 1 \\ v2 & v2 & v2 & 1 \\ v3 & v3 & v3 & v3 & 1 \end{bmatrix}$$

```

Include Files

- mkl_scalapack.h

Description

The p?larz function applies a real/complex elementary reflector Q (or Q^T) to a real/complex m -by- n distributed matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$, from either the left or the right. Q is represented in the form

$$Q = I - \tau v v',$$

where τ is a real/complex scalar and v is a real/complex vector.

If $\tau = 0$, then Q is taken to be the unit matrix.

Q is a product of k elementary reflectors as returned by p?tzrzf.

Input Parameters

<i>side</i>	(global) if <i>side</i> = 'L': form $Q * \text{sub}(C)$, if <i>side</i> = 'R': form $\text{sub}(C) * Q$, $Q = Q^T$ (for real flavors).
<i>m</i>	(global) The number of rows in the distributed matrix $\text{sub}(C)$. ($m \geq 0$).
<i>n</i>	(global) The number of columns in the distributed matrix $\text{sub}(C)$. ($n \geq 0$).
<i>l</i>	(global) The columns of the distributed matrix $\text{sub}(A)$ containing the meaningful part of the Householder reflectors. If <i>side</i> = 'L', $m \geq l \geq 0$,

	if $side = 'R', n_{\geq 1} \geq 0$.
v	(local). Pointer into the local memory to an array of size $lld_v * LOCc(n_v)$ containing the local pieces of the global distributed matrix V representing the Householder transformation Q, $V(iv:iv+l-1, jv)$ if $side = 'L'$ and $incv = 1$, $V(iv, jv:jv+l-1)$ if $side = 'L'$ and $incv = m_v$, $V(iv:iv+l-1, jv)$ if $side = 'R'$ and $incv = 1$, $V(iv, jv:jv+l-1)$ if $side = 'R'$ and $incv = m_v$. The vector v in the representation of Q. v is not used if $tau = 0$.
iv, jv	(global) The row and column indices in the global distributed matrix V indicating the first row and the first column of the matrix $sub(V)$, respectively.
$descv$	(global and local) array of size $dlen_$. The array descriptor for the distributed matrix V .
$incv$	(global) The global increment for the elements of V. Only two values of $incv$ are supported in this version, namely 1 and m_v. $incv$ must not be zero.
tau	(local) Array of size $LOCc(jv)$ if $incv = 1$, and $LOCr(iv)$ otherwise. This array contains the Householder scalars related to the Householder vectors. tau is tied to the distributed matrix V.
c	(local). Pointer into the local memory to an array of size $lld_c * LOCc(jc+n-1)$, containing the local pieces of $sub(C)$.
ic, jc	(global) The row and column indices in the global matrix C indicating the first row and the first column of the matrix $sub(C)$, respectively.
$descC$	(global and local) array of size $dlen_$. The array descriptor for the distributed matrix C .
$work$	(local). Array of size $lwork$ If $incv = 1$, if $side = 'L'$, if $ivcol = iccol$, $lwork \geq NqC0$ else

```

        lwork ≥ MpC0 + max(1, NqC0)
    end if
else if side = 'R' ,
    lwork ≥ NqC0 + max(max(1, MpC0), numroc(numroc(n+icoffc,nb_v,
0,0,npcol),nb_v,0,0,lcmq))
end if
else if incv = m_v,
    if side = 'L' ,
        lwork ≥ MpC0 + max(max(1, NqC0), numroc(numroc(m+iroffc,mb_v,
0,0,nprow),mb_v,0,0,lcmp))
    else if side = 'R' ,
        if ivrow = icrow,
            lwork ≥ MpC0
        else
            lwork ≥ NqC0 + max(1, MpC0)
        end if
    end if
end if.

```

Here *lcm* is the least common multiple of *nprow* and *npcol* and

lcm = ilcm(*nprow*, *npcol*), *lcmp* = *lcm* / *nprow*,

lcmq = *lcm* / *npcol*,

iroffc = mod(*ic*-1, *mb_c*), *icoffc* = mod(*jc*-1, *nb_c*),

icrow = indxg2p(*ic*, *mb_c*, *myrow*, *rsrc_c*, *nprow*),

iccol = indxg2p(*jc*, *nb_c*, *mycol*, *csrc_c*, *npcol*),

mpc0 = numroc(*m*+*iroffc*, *mb_c*, *myrow*, *icrow*, *nprow*),

nqc0 = numroc(*n*+*icoffc*, *nb_c*, *mycol*, *iccol*, *npcol*),

ilcm, *indxg2p*, and *numroc* are ScaLAPACK tool functions; *myrow*, *mycol*, *nprow*, and *npcol* can be determined by calling the function *blacs_gridinfo*.

Output Parameters

c

(local).

On exit, *sub(C)* is overwritten by the $Q \cdot \text{sub}(C)$ if *side* = 'L', or $\text{sub}(C) \cdot Q$ if *side* = 'R'.

MKL_INT *descc , MKL_Complex16 *work );
```

Include Files

- mkl_scalapack.h

Description

The p?larzb function applies a real/complex block reflector Q or its transpose Q^T (conjugate transpose Q^H for complex flavors) to a real/complex distributed m -by- n matrix sub(C) = $C(ic:ic+m-1, jc:jc+n-1)$ from the left or the right.

Q is a product of k elementary reflectors as returned by p?tzzrf.

Currently, only *storev* = 'R' and *direct* = 'B' are supported.

Input Parameters

<i>side</i>	(global) if <i>side</i> = 'L': apply Q or Q^T (Q^H for complex flavors) from the Left; if <i>side</i> = 'R': apply Q or Q^T (Q^H for complex flavors) from the Right.
<i>trans</i>	(global) if <i>trans</i> = 'N': No transpose, apply Q ; If <i>trans</i> ='T': Transpose, apply Q^T (real flavors); If <i>trans</i> ='C': Conjugate transpose, apply Q^H (complex flavors).
<i>direct</i>	(global) Indicates how H is formed from a product of elementary reflectors.

	if <i>direct</i> = 'F': $H = H(1) * H(2) * \dots * H(k)$ - forward (not supported) ; if <i>direct</i> = 'B': $H = H(k) * \dots * H(2) * H(1)$ - backward.
<i>storev</i>	(global) Indicates how the vectors that define the elementary reflectors are stored: if <i>storev</i> = 'C': columnwise (not supported) . if <i>storev</i> = 'R': rowwise.
<i>m</i>	(global) The number of rows in the distributed submatrix <i>sub</i>(C). ($m \geq 0$) .
<i>n</i>	(global) The number of columns in the distributed submatrix <i>sub</i>(C). ($n \geq 0$) .
<i>k</i>	(global) The order of the matrix <i>T</i>. (= the number of elementary reflectors whose product defines the block reflector).
<i>l</i>	(global) The columns of the distributed submatrix <i>sub</i>(A) containing the meaningful part of the Householder reflectors. If <i>side</i> = 'L', $m \geq l \geq 0$, if <i>side</i> = 'R', $n \geq l \geq 0$.
<i>v</i>	(local). Pointer into the local memory to an array of size $lld\_v * LOCc(jv+m-1)$ if <i>side</i> = 'L', $lld\_v * LOCc(jv+m-1)$ if <i>side</i> = 'R'. It contains the local pieces of the distributed vectors <i>V</i> representing the Householder transformation as returned by <code>p?tzrzf</code>. $lld\_v \geq LOCr(iv+k-1)$.
<i>iv, jv</i>	(global) The row and column indices in the global matrix <i>V</i> indicating the first row and the first column of the submatrix <i>sub</i>(V), respectively.
<i>descv</i>	(global and local) array of size <i>dlen_</i>. The array descriptor for the distributed matrix <i>V</i>.
<i>t</i>	(local) Array of size $mb\_v * mb\_v$. The lower triangular matrix <i>T</i> in the representation of the block reflector.
<i>c</i>	(local). Pointer into the local memory to an array of size $lld\_c * LOCc(jc+n-1)$. On entry, the <i>m</i>-by-<i>n</i> distributed matrix <i>sub</i>(C).
<i>ic, jc</i>	(global)

The row and column indices in the global matrix *C* indicating the first row and the first column of the submatrix *sub(C)*, respectively.

desc

(global and local) array of size *dlen_*. The array descriptor for the distributed matrix *C*.

work

(local).

Array of size *lwork*.

```
If storev = 'C' ,
    if side = 'L' ,
        lwork ≥ (nqc0 + mpc0) * k
    else if side = 'R' ,
        lwork ≥ (nqc0 + max(npv0 + numroc(numroc(n+icoffc, nb_v, 0, 0,
            npcol),
                nb_v, 0, 0, lcmq), mpc0)) * k
    end if
else if storev = 'R' ,
    if side = 'L' ,
        lwork ≥ (mpc0 + max(mqv0 + numroc(numroc(m+iroffc, mb_v, 0, 0, nprow),
            mb_v, 0, 0, lcmp), nqc0)) * k
    else if side = 'R' ,
        lwork ≥ (mpc0 + nqc0) * k
    end if
end if.
```

Here $lcmq = lcm/npcol$ with $lcm = iclm(nprow, npcol)$,
 $iroffv = \text{mod}(iv-1, mb_v)$, $icoffv = \text{mod}(jv-1, nb_v)$,
 $ivrow = \text{indxg2p}(iv, mb_v, myrow, rsrc_v, nprow)$,
 $ivcol = \text{indxg2p}(jv, nb_v, mycol, csrc_v, npcol)$,
 $mqv0 = \text{numroc}(m+icoffv, nb_v, mycol, ivcol, npcol)$,
 $npv0 = \text{numroc}(n+iroffv, mb_v, myrow, ivrow, nprow)$,
 $iroffc = \text{mod}(ic-1, mb_c)$, $icoffc = \text{mod}(jc-1, nb_c)$,
 $icrow = \text{indxg2p}(ic, mb_c, myrow, rsrc_c, nprow)$,
 $iccol = \text{indxg2p}(jc, nb_c, mycol, csrc_c, npcol)$,
 $mpc0 = \text{numroc}(m+iroffc, mb_c, myrow, icrow, nprow)$,
 $npc0 = \text{numroc}(n+icoffc, mb_c, myrow, icrow, nprow)$,
 $nqc0 = \text{numroc}(n+icoffc, nb_c, mycol, iccol, npcol)$,
 $ilcm$, indxg2p , and numroc are ScaLAPACK tool functions; $myrow$, $mycol$,
 $nprow$, and $npcol$ can be determined by calling the function
`blacs_gridinfo`.

Output Parameters

c (local).
On exit, $\text{sub}(C)$ is overwritten by the $Q^* \text{sub}(C)$, or $Q'^* \text{sub}(C)$, or $\text{sub}(C) * Q$, or $\text{sub}(C) * Q'$, where Q' is the transpose (conjugate transpose) of Q .

Description

The `p?larzc` function applies a complex elementary reflector Q^H to a complex m -by- n distributed matrix $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$, from either the left or the right. Q is represented in the form

$$Q = I - \tau v v^H,$$

where τ is a complex scalar and v is a complex vector.

If $\tau = 0$, then Q is taken to be the unit matrix.

Q is a product of k elementary reflectors as returned by `p?tzrf`.

Input Parameters

side (global)
if *side* = 'L': form $Q^H \text{sub}(C)$;
if *side* = 'R': form $\text{sub}(C) * Q^H$.

m (global)
The number of rows in the distributed matrix $\text{sub}(C)$. ($m \geq 0$).

n (global)
The number of columns in the distributed matrix $\text{sub}(C)$. ($n \geq 0$).

l (global)

The columns of the distributed matrix $\text{sub}(A)$ containing the meaningful part of the Householder reflectors.

If $\text{side} = 'L', m \geq l \geq 0$,

if $\text{side} = 'R', n \geq l \geq 0$.

v (local).

Pointer into the local memory to an array of size $lld_v * LOCc(n_v)$ containing the local pieces of the global distributed matrix V representing the Householder transformation Q ,

$V(iv:iv+l-1, jv)$ if $\text{side} = 'L'$ and $incv = 1$,

$V(iv, jv:jv+l-1)$ if $\text{side} = 'L'$ and $incv = m_v$,

$V(iv:iv+l-1, jv)$ if $\text{side} = 'R'$ and $incv = 1$,

$V(iv, jv:jv+l-1)$ if $\text{side} = 'R'$ and $incv = m_v$.

The vector v in the representation of Q . v is not used if $\tau = 0$.

iv, jv (global)

The row and column indices in the global matrix V indicating the first row and the first column of the matrix $\text{sub}(V)$, respectively.

$descv$ (global and local) array of size $dlen_$. The array descriptor for the distributed matrix V .

$incv$ (global)

The global increment for the elements of V . Only two values of $incv$ are supported in this version, namely 1 and m_v .

$incv$ must not be zero.

τ (local)

Array of size $LOCc(jv)$ if $incv = 1$, and $LOCr(iv)$ otherwise. This array contains the Householder scalars related to the Householder vectors.

τ is tied to the distributed matrix V .

c (local).

Pointer into the local memory to an array of size $lld_c * LOCc(jc+n-1)$, containing the local pieces of $\text{sub}(C)$.

ic, jc (global)

The row and column indices in the global matrix C indicating the first row and the first column of the matrix $\text{sub}(C)$, respectively.

$desc$ (global and local) array of size $dlen_$. The array descriptor for the distributed matrix C .

$work$ (local).

```
If incv = 1,
    if side = 'L' ,
        if icol = iccol,
            lwork ≥ nqc0
```

```

else
    lwork ≥ mpc0 + max(1, nqc0)
end if
else if side = 'R' ,
    lwork ≥ nqc0 + max(max(1, mpc0), numroc(numroc(n+icoffc, nb_v, 0, 0,
npcol),
        nb_v, 0, 0, lcmq)) end if
else if incv = m_v,
    if side = 'L' ,
        lwork ≥ mpc0 + max(max(1, nqc0), numroc(numroc(m+iroffc, mb_v, 0, 0,
nprow),
            mb_v, 0, 0, lcmq))
    else if side = 'R',
        if ivrow = icrow,
            lwork ≥ mpc0
        else
            lwork ≥ nqc0 + max(1, mpc0)
        end if
    end if
end if
end if

```

Here *lcm* is the least common multiple of *nprow* and *npcol*;

```

lcm = ilcm(nprow, npcol), lcmq = lcm/nprow, lcmq = lcm/npcol,
iroffc = mod(ic-1, mb_c), icoffc = mod(jc-1, nb_c),
icrow = indxg2p(ic, mb_c, myrow, rsrc_c, nprow),
iccol = indxg2p(jc, nb_c, mycol, csrc_c, npcol),
mpc0 = numroc(m+iroffc, mb_c, myrow, icrow, nprow),
nqc0 = numroc(n+icoffc, nb_c, mycol, iccol, npcol),
ilcm, indxg2p, and numroc are ScaLAPACK tool functions;

```

myrow, *mycol*, *nprow*, and *npcol* can be determined by calling the function `blacs_gridinfo`.

Output Parameters

c (local).

On exit, `sub(C)` is overwritten by the $Q^H \cdot \text{sub}(C)$ if *side* = 'L', or $\text{sub}(C) \cdot Q^H$ if *side* = 'R'.

*t , MKL_Complex16 *work );

```

Include Files

- mkl_scalapack.h

Description

The `p?larzt` function forms the triangular factor T of a real/complex block reflector H of order greater than n , which is defined as a product of k elementary reflectors as returned by `p?tzzrf`.

If `direct` = 'F', $H = H(1) * H(2) * \dots * H(k)$, and T is upper triangular;

If `direct` = 'B', $H = H(k) * \dots * H(2) * H(1)$, and T is lower triangular.

If `storev` = 'C', the vector which defines the elementary reflector $H(i)$, is stored in the i -th column of the array v , and

$$H = I - v * t * v'.$$

If `storev` = 'R', the vector, which defines the elementary reflector $H(i)$, is stored in the i -th row of the array v , and

$$H = I - v' * t * v$$

Currently, only `storev` = 'R' and `direct` = 'B' are supported.

Input Parameters

<code>direct</code>	(global)
Specifies the order in which the elementary reflectors are multiplied to form the block reflector:	
if <code>direct</code> = 'F': $H = H(1) * H(2) * \dots * H(k)$ (Forward, not supported)	
if <code>direct</code> = 'B': $H = H(k) * \dots * H(2) * H(1)$ (Backward).	
<code>storev</code>	(global)
Specifies how the vectors which defines the elementary reflectors are stored:	
if <code>storev</code> = 'C': columnwise (not supported);	
if <code>storev</code> = 'R': rowwise.	
<code>n</code>	(global)
The order of the block reflector H . $n \geq 0$.	
<code>k</code>	(global)
The order of the triangular factor T (= the number of elementary reflectors).	
$1 \leq k \leq mb\_v (= nb\_v)$.	

v	Pointer into the local memory to an array of local size $LOCr(iv+k-1) * LOCc(jv+n-1)$. The distributed matrix V contains the Householder vectors. See <i>Application Notes</i> below.
iv, jv	(global) The row and column indices in the global matrix V indicating the first row and the first column of the matrix sub(V), respectively.
$descv$	(local) array of size $dlen\_$. The array descriptor for the distributed matrix V .
τ	(local) Array of size $LOCr(iv+k-1)$ if $incv = m\_v$, and $LOCc(jv+k-1)$ otherwise. This array contains the Householder scalars related to the Householder vectors. τ is tied to the distributed matrix V .
$work$	(local). Workspace array of size $(k*(k-1)/2)$.

Output Parameters

v	
t	(local) Array of size $mb\_v * mb\_v$. It contains the k -by- k triangular factor of the block reflector associated with v . t is lower triangular.

Application Notes

The shape of the matrix V and the storage of the vectors which define the $H(i)$ is best illustrated by the following example with $n = 5$ and $k = 3$. The elements equal to 1 are not stored; the corresponding array elements are modified but restored on exit. The rest of the array is not used.

$direct='F'$ and $storev='C'$

$$v = \begin{bmatrix} v1 & v2 & v3 \\ v1 & v2 & v3 \\ v1 & v2 & v3 \\ v1 & v2 & v3 \\ v1 & v2 & v3 \end{bmatrix}$$

$$v = \begin{bmatrix} . & . & . \\ . & . & . \\ 1 & . & . \\ & 1 & . \\ & & 1 \end{bmatrix}$$

$direct='F'$ and $storev='R'$:

$$\begin{bmatrix} \overbrace{v1 \ v1 \ v1 \ v1 \ v1}^v & . & . & . & 1 \\ v2 \ v2 \ v2 \ v2 \ v2 & . & . & . & 1 \\ v3 \ v3 \ v3 \ v3 \ v3 & . & . & 1 & \end{bmatrix}$$

direct='B' and *storev*='C':

$$v = \begin{bmatrix} 1 & & & & \\ & 1 & & & \\ & & 1 & & \\ & & & \ddots & \\ & & & & 1 \end{bmatrix} \begin{bmatrix} v1 & v2 & v3 \\ v1 & v2 & v3 \\ v1 & v2 & v3 \\ v1 & v2 & v3 \\ v1 & v2 & v3 \end{bmatrix}$$

direct='B' and *storev*='R':

$$\begin{bmatrix} 1 & . & . & . & \overbrace{v1 \ v1 \ v1 \ v1 \ v1}^v \\ . & 1 & . & . & v2 \ v2 \ v2 \ v2 \ v2 \\ . & . & 1 & . & v3 \ v3 \ v3 \ v3 \ v3 \end{bmatrix}$$

p?lascl

Multiplies a general rectangular matrix by a real scalar
defined as C_{to}/C_{from} .

Syntax

```
void pslascl (char *type , float *cfrom , float *cto , MKL_INT *m , MKL_INT *n , float
*a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
```

```
void pdlascl (char *type , double *cfrom , double *cto , MKL_INT *m , MKL_INT *n ,
double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
```

```
void pclascl (char *type , float *cfrom , float *cto , MKL_INT *m , MKL_INT *n ,
MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
```

```
void pzlascl (char *type , double *cfrom , double *cto , MKL_INT *m , MKL_INT *n ,
MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The `p?lascl` function multiplies the m -by- n real/complex distributed matrix sub(A) denoting $A(ia:ia+m-1, ja:ja+n-1)$ by the real/complex scalar $cto/cfrom$. This is done without over/underflow as long as the final result $cto*A(i,j)/cfrom$ does not over/underflow. *type* specifies that sub(A) may be full, upper triangular, lower triangular or upper Hessenberg.

Input Parameters

type (global)

type indicates the storage type of the input distributed matrix.

if *type* = 'G': sub(*A*) is a full matrix,

if *type* = 'L': sub(*A*) is a lower triangular matrix,

if *type* = 'U': sub(*A*) is an upper triangular matrix,

if *type* = 'H': sub(*A*) is an upper Hessenberg matrix.

cfrom, cto

(global)

The distributed matrix sub(*A*) is multiplied by *cto/cfrom*. *A*(*i,j*) is computed without over/underflow if the final result *cto***A*(*i,j*)/*cfrom* can be represented without over/underflow. *cfrom* must be nonzero.

m

(global)

The number of rows in the distributed matrix sub(*A*). (*m* ≥ 0).

n

(global)

The number of columns in the distributed matrix sub(*A*). (*n* ≥ 0).

a

(local input/local output)

Pointer into the local memory to an array of size *lld_a* * *LOCc*(*ja*+*n*-1).

This array contains the local pieces of the distributed matrix sub(*A*).

ia, ja

(global)

The column and row indices in the global matrix *A* indicating the first row and column of the matrix sub(*A*), respectively.

desca

(global and local)

Array of size *dlen_*. The array descriptor for the distributed matrix *A*.

Output Parameters

a

(local).

On exit, this array contains the local pieces of the distributed matrix multiplied by *cto/cfrom*.

info

(local)

if *info* = 0: the execution is successful.

if *info* < 0: If the *i*-th argument is an array and the *j*-th entry, indexed *j*-1, had an illegal value, then *info* = -(*i**100+*j*),

if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

p?laset

Initializes the offdiagonal elements of a matrix to alpha and the diagonal elements to beta.

Syntax

```
void pslaset (char *uplo , MKL_INT *m , MKL_INT *n , float *alpha , float *beta ,
float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );

void pdlaset (char *uplo , MKL_INT *m , MKL_INT *n , double *alpha , double *beta ,
double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );

void pclaset (char *uplo , MKL_INT *m , MKL_INT *n , MKL_Complex8 *alpha , MKL_Complex8
*beta , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );

void pzaset (char *uplo , MKL_INT *m , MKL_INT *n , MKL_Complex16 *alpha ,
MKL_Complex16 *beta , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );
```

Include Files

- mkl_scalapack.h

Description

The `p?laset` function initializes an m -by- n distributed matrix $\text{sub}(A)$ denoting $A(ia:ia+m-1, ja:ja+n-1)$ to β on the diagonal and α on the offdiagonals.

Input Parameters

<i>uplo</i>	(global) Specifies the part of the distributed matrix $\text{sub}(A)$ to be set: if <i>uplo</i> = 'U': upper triangular part; the strictly lower triangular part of $\text{sub}(A)$ is not changed; if <i>uplo</i> = 'L': lower triangular part; the strictly upper triangular part of $\text{sub}(A)$ is not changed. Otherwise: all of the matrix $\text{sub}(A)$ is set.
<i>m</i>	(global) The number of rows in the distributed matrix $\text{sub}(A)$. ($m \geq 0$).
<i>n</i>	(global) The number of columns in the distributed matrix $\text{sub}(A)$. ($n \geq 0$).
<i>alpha</i>	(global). The constant to which the offdiagonal elements are to be set.
<i>beta</i>	(global). The constant to which the diagonal elements are to be set.

Output Parameters

<i>a</i>	(local). Pointer into the local memory to an array of size $lld\_a * LOCc(ja+n-1)$. This array contains the local pieces of the distributed matrix $\text{sub}(A)$ to be set. On exit, the leading m -by- n matrix $\text{sub}(A)$ is set as follows: if <i>uplo</i> = 'U', $A(ia+i-1, ja+j-1) = \alpha, 1 \leq i \leq j-1, 1 \leq j \leq n$, if <i>uplo</i> = 'L', $A(ia+i-1, ja+j-1) = \alpha, j+1 \leq i \leq m, 1 \leq j \leq n$,

otherwise, $A(ia+i-1, ja+j-1) = \alpha$, $1 \leq i \leq m$, $1 \leq j \leq n$, $ia+i \neq ja+j$, and, for all $uplo$, $A(ia+i-1, ja+i-1) = \beta$, $1 \leq i \leq \min(m, n)$.

ia, ja

(global)

The column and row indices in the distributed matrix *A* indicating the first row and column of the matrix sub(*A*), respectively.

desca

(global and local)

Array of size *dlen_*. The array descriptor for the distributed matrix *A*.

See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

p?lasmsub

Looks for a small subdiagonal element from the bottom of the matrix that it can safely set to zero.

Syntax

```
void pslasmsub (float *a , MKL_INT *desca , MKL_INT *i , MKL_INT *l , MKL_INT *k ,
float *smlnum , float *buf , MKL_INT *lwork );
```

```
void pdlasmsub (double *a , MKL_INT *desca , MKL_INT *i , MKL_INT *l , MKL_INT *k ,
double *smlnum , double *buf , MKL_INT *lwork );
```

Include Files

- mkl_scalapack.h

Description

The p?lasmsub function looks for a small subdiagonal element from the bottom of the matrix that it can safely set to zero. This function does a global maximum and must be called by all processes.

Input Parameters

a

(global)

Array of size *lld_a* * *LOCc(n_a)*.

On entry, the Hessenberg matrix whose tridiagonal part is being scanned. Unchanged on exit.

desca

(global and local)

Array of size *dlen_*. The array descriptor for the distributed matrix *A*.

i

(global)

The global location of the bottom of the unreduced submatrix of *A*. Unchanged on exit.

l

(global)

The global location of the top of the unreduced submatrix of *A*. Unchanged on exit.

smlnum

(global)

On entry, a "small number" for the given matrix. Unchanged on exit. A suggested value for *smlnum* is `slamch('s') * (n/slamch('p'))` for `pslasmsub` or `dlamch('s') * (n/dlamch('p'))` for `pdlasmsub`. See [lamch](#).

lwork

(global)

On exit, *lwork* is the size of the work buffer.

This must be at least $2 * \text{ceil}(\text{ceil}((i-1)/\text{hbl}) / \text{lcm}(\text{nprow}, \text{npcol}))$. Here `lcm` is least common multiple, and *nprow**npcol* is the logical grid size.

Output Parameters

k

(global)

On exit, this yields the bottom portion of the unreduced submatrix. This will satisfy: $1 \leq m \leq i-1$.

buf

(local).

Array of size *lwork*.

See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

p?lassq

Updates a sum of squares represented in scaled form.

Syntax

```
void pslasq (MKL_INT *n , float *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx ,
MKL_INT *incx , float *scale , float *sumsq );
```

```
void pdlasq (MKL_INT *n , double *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx ,
MKL_INT *incx , double *scale , double *sumsq );
```

```
void pclasq (MKL_INT *n , MKL_Complex8 *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx , float *scale , float *sumsq );
```

```
void pzlasq (MKL_INT *n , MKL_Complex16 *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx , double *scale , double *sumsq );
```

Include Files

- `mkl_scalapack.h`

Description

The `p?lassq` function returns the values *scl* and *smsq* such that

$$scl^2 * smsq = x_1^2 + \dots + x_n^2 + scale^2 * sumsq,$$

where

$x_i = \text{sub}(X) = X(ix + (jx-1)*m_x + (i-1)*incx)$ for `pslasq`/`pdlasq`,

$x_i = \text{sub}(X) = \text{abs}(X(ix + (jx-1)*m_x + (i-1)*incx))$ for `pclasq`/`pzlasq`.

For real functions `pslasq`/`pdlasq` the value of *sumsq* is assumed to be non-negative and *scl* returns the value

$$scl = \max(scale, \text{abs}(x_i)).$$

For complex functions `pclassq/pzlassq` the value of *sumsq* is assumed to be at least unity and the value of *ssq* will then satisfy

$$1.0 \leq ssq \leq sumsq + 2n$$

Value *scale* is assumed to be non-negative and *scl* returns the value

$$scl = \max_i \left(scale, \text{abs}(\text{real}(x_i)), \text{abs}(\text{aimag}(x_i)) \right)$$

For all functions `p?lassq` values *scale* and *sumsq* must be supplied in *scale* and *sumsq* respectively, and *scale* and *sumsq* are overwritten by *scl* and *ssq* respectively.

All functions `p?lassq` make only one pass through the vector `sub(X)`.

Input Parameters

<i>n</i>	(global) The length of the distributed vector <code>sub(x)</code> .
<i>x</i>	The array that stores the vector for which a scaled sum of squares is computed: $x[ix + (jx-1)*m\_x + i*incx], 0 \leq i < n.$
<i>ix</i>	(global) The row index in the global matrix <i>X</i> indicating the first row of <code>sub(X)</code> .
<i>jx</i>	(global) The column index in the global matrix <i>X</i> indicating the first column of <code>sub(X)</code> .
<i>descx</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>X</i> .
<i>incx</i>	(global) The global increment for the elements of <i>X</i> . Only two values of <i>incx</i> are supported in this version, namely 1 and <i>m_x</i> . The argument <i>incx</i> must not equal zero.
<i>scale</i>	(local). On entry, the value <i>scale</i> in the equation above.
<i>sumsq</i>	(local) On entry, the value <i>sumsq</i> in the equation above.

Output Parameters

<i>scale</i>	(local). On exit, <i>scale</i> is overwritten with <i>scl</i> , the scaling factor for the sum of squares.
<i>sumsq</i>	(local).

On exit, *sumsq* is overwritten with the value *smsq*, the basic sum of squares from which *scf* has been factored out.

See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

p?laswp

Performs a series of row interchanges on a general rectangular matrix.

Syntax

```
void pslaswp (char *direc , char *rowcol , MKL_INT *n , float *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_INT *k1 , MKL_INT *k2 , MKL_INT *ipiv );

void pdlaswp (char *direc , char *rowcol , MKL_INT *n , double *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_INT *k1 , MKL_INT *k2 , MKL_INT *ipiv );

void pclaswp (char *direc , char *rowcol , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_INT *k1 , MKL_INT *k2 , MKL_INT *ipiv );

void pzlaswp (char *direc , char *rowcol , MKL_INT *n , MKL_Complex16 *a , MKL_INT
*ia , MKL_INT *ja , MKL_INT *desca , MKL_INT *k1 , MKL_INT *k2 , MKL_INT *ipiv );
```

Include Files

- `mk1_scalapack.h`

Description

The `p?laswp` function performs a series of row or column interchanges on the distributed matrix $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$. One interchange is initiated for each of rows or columns $k1$ through $k2$ of $\text{sub}(A)$. This function assumes that the pivoting information has already been broadcast along the process row or column. Also note that this function will only work for $k1$ - $k2$ being in the same *mb* (or *nb*) block. If you want to pivot a full matrix, use `p?lapiv`.

Input Parameters

<i>direc</i>	(global) Specifies in which order the permutation is applied: = 'F' - forward, = 'B' - backward.
<i>rowcol</i>	(global) Specifies if the rows or columns are permuted: = 'R' - rows, = 'C' - columns.
<i>n</i>	(global) If <i>rowcol</i> ='R', the length of the rows of the distributed matrix $A(*, ja:ja+n-1)$ to be permuted; If <i>rowcol</i> ='C', the length of the columns of the distributed matrix $A(ia:ia+n-1, *)$ to be permuted;

<i>a</i>	(local) Pointer into the local memory to an array of size $lld\_a * LOCc(n\_a)$. On entry, this array contains the local pieces of the distributed matrix to which the row/columns interchanges will be applied.
<i>ia</i>	(global) The row index in the global matrix <i>A</i> indicating the first row of sub(<i>A</i>).
<i>ja</i>	(global) The column index in the global matrix <i>A</i> indicating the first column of sub(<i>A</i>).
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .
<i>k1</i>	(global) The first element of <i>ipiv</i> for which a row or column interchange will be done.
<i>k2</i>	(global) The last element of <i>ipiv</i> for which a row or column interchange will be done.
<i>ipiv</i>	(local) Array of size $LOCr(m\_a) + mb\_a$ for row pivoting and $LOCr(n\_a) + nb\_a$ for column pivoting. This array is tied to the matrix <i>A</i> , <i>ipiv</i> [<i>k</i>]=1 implies rows (or columns) <i>k</i> +1 and <i>l</i> are to be interchanged, <i>k</i> = 0, 1, ..., size (<i>ipiv</i>) -1.

Output Parameters

<i>A</i>	(local) On exit, the permuted distributed matrix.

See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

p?latra

Computes the trace of a general square distributed matrix.

Syntax

```
float pslatra (MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );
double pdlatra (MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );
void pclatra (MKL_Complex8 * , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );
void pzlatra (MKL_Complex16 * , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );
```

Include Files

- `mk1_scalapack.h`

Description

This function computes the trace of an n -by- n distributed matrix $\text{sub}(A)$ denoting $A(ia:ia+n-1, ja:ja+n-1)$. The result is left on every process of the grid.

Input Parameters

n	(global) The number of rows and columns to be operated on, that is, the order of the distributed matrix $\text{sub}(A)$. $n \geq 0$.
a	(local). Pointer into the local memory to an array of size $lld\_a * LOCc(ja+n-1)$ containing the local pieces of the distributed matrix, the trace of which is to be computed.
ia, ja	(global) The row and column indices respectively in the global matrix A indicating the first row and the first column of the matrix $\text{sub}(A)$, respectively.
$desca$	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix A .

Output Parameters

val	The value returned by the function.

See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

p?latrd

Reduces the first nb rows and columns of a symmetric/Hermitian matrix A to real tridiagonal form by an orthogonal/unitary similarity transformation.

Syntax

```
void pslatrd (char *uplo , MKL_INT *n , MKL_INT *nb , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *d , float *e , float *tau , float *w , MKL_INT *iw , MKL_INT *jw , MKL_INT *descw , float *work );
```

```
void pdlatrd (char *uplo , MKL_INT *n , MKL_INT *nb , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *d , double *e , double *tau , double *w , MKL_INT *iw , MKL_INT *jw , MKL_INT *descw , double *work );
```

```
void pclatrd (char *uplo , MKL_INT *n , MKL_INT *nb , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *d , float *e , MKL_Complex8 *tau , MKL_Complex8 *w , MKL_INT *iw , MKL_INT *jw , MKL_INT *descw , MKL_Complex8 *work );
```

```
void pzlatrd (char *uplo , MKL_INT *n , MKL_INT *nb , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *d , double *e , MKL_Complex16 *tau , MKL_Complex16 *w , MKL_INT *iw , MKL_INT *jw , MKL_INT *descw , MKL_Complex16 *work );
```

Include Files

- mkl_scalapack.h

Description

The `p?latrd` function reduces nb rows and columns of a real symmetric or complex Hermitian matrix $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$ to symmetric/complex tridiagonal form by an orthogonal/unitary similarity transformation $Q' * \text{sub}(A) * Q$, and returns the matrices V and W , which are needed to apply the transformation to the unreduced part of $\text{sub}(A)$.

If $uplo = U$, `p?latrd` reduces the last nb rows and columns of a matrix, of which the upper triangle is supplied;

if $uplo = L$, `p?latrd` reduces the first nb rows and columns of a matrix, of which the lower triangle is supplied.

This is an auxiliary function called by `p?sytrd`/`p?hetrd`.

Input Parameters

<code>uplo</code>	(global) Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix $\text{sub}(A)$ is stored: = 'U': Upper triangular = L: Lower triangular.
<code>n</code>	(global) The number of rows and columns to be operated on, that is, the order of the distributed matrix $\text{sub}(A)$. $n \geq 0$.
<code>nb</code>	(global) The number of rows and columns to be reduced.
<code>a</code>	Pointer into the local memory to an array of size $lld\_a * LOCC(ja+n-1)$. On entry, this array contains the local pieces of the symmetric/Hermitian distributed matrix $\text{sub}(A)$. If $uplo = U$, the leading n -by- n upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and its strictly lower triangular part is not referenced. If $uplo = L$, the leading n -by- n lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the matrix, and its strictly upper triangular part is not referenced.
<code>ia</code>	(global) The row index in the global matrix A indicating the first row of $\text{sub}(A)$.
<code>ja</code>	(global) The column index in the global matrix A indicating the first column of $\text{sub}(A)$.
<code>desca</code>	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix A .
<code>iw</code>	(global) The row index in the global matrix W indicating the first row of $\text{sub}(W)$.

<i>jw</i>	(global) The column index in the global matrix <i>W</i> indicating the first column of sub(<i>W</i>).
<i>descw</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>W</i> .
<i>work</i>	(local) Workspace array of size <i>nb_a</i> .

Output Parameters

<i>a</i>	(local) On exit, if <i>uplo</i> = 'U', the last <i>nb</i> columns have been reduced to tridiagonal form, with the diagonal elements overwriting the diagonal elements of sub(<i>A</i>); the elements above the diagonal with the array <i>tau</i> represent the orthogonal/unitary matrix <i>Q</i> as a product of elementary reflectors; if <i>uplo</i> = 'L', the first <i>nb</i> columns have been reduced to tridiagonal form, with the diagonal elements overwriting the diagonal elements of sub(<i>A</i>); the elements below the diagonal with the array <i>tau</i> represent the orthogonal/unitary matrix <i>Q</i> as a product of elementary reflectors.
<i>d</i>	(local) Array of size <i>LOCc(ja+n-1)</i> . The diagonal elements of the tridiagonal matrix <i>T</i> : $d[i] = A(i+1, i+1)$, $i = 0, 1, \dots, LOCc(ja+n-1)-1$. <i>d</i> is tied to the distributed matrix <i>A</i> .
<i>e</i>	(local) Array of size <i>LOCc(ja+n-1)</i> if <i>uplo</i> = 'U', <i>LOCc(ja+n-2)</i> otherwise. The off-diagonal elements of the tridiagonal matrix <i>T</i> : $e[i] = A(i+1, i+2)$ if <i>uplo</i> = 'U', $e[i] = A(i+2, i+1)$ if <i>uplo</i> = 'L', $i = 0, 1, \dots, LOCc(ja+n-1)-1$. <i>e</i> is tied to the distributed matrix <i>A</i> .
<i>tau</i>	(local) Array of size <i>LOCc(ja+n-1)</i> . This array contains the scalar factors of the elementary reflectors. <i>tau</i> is tied to the distributed matrix <i>A</i> .
<i>w</i>	(local) Pointer into the local memory to an array of size <i>lld_w</i> * <i>nb_w</i> . This array contains the local pieces of the <i>n</i> -by- <i>nb_w</i> matrix <i>w</i> required to update the unreduced part of sub(<i>A</i>).

Application Notes

If *uplo* = 'U', the matrix *Q* is represented as a product of elementary reflectors

$$Q = H(n) * H(n-1) * \dots * H(n-nb+1)$$

Each $H(i)$ has the form

$$H(i) = I - \tau v v^*,$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(i:n) = 0$ and $v(i-1) = 1$; $v(1:i-1)$ is stored on exit in $A(ia:ia+i-1, ja+i)$, and τ in $\tau[ja+i-2]$.

If $uplo = L$, the matrix Q is represented as a product of elementary reflectors

$$Q = H(1)H(2)\dots H(nb)$$

Each $H(i)$ has the form

$$H(i) = I - \tau v v^*,$$

where τ is a real/complex scalar, and v is a real/complex vector with $v(1:i) = 0$ and $v(i+1) = 1$; $v(i+2:n)$ is stored on exit in $A(ia+i+1:ia+n-1, ja+i-1)$, and τ in $\tau[ja+i-2]$.

The elements of the vectors v together form the n -by- nb matrix V which is needed, with W , to apply the transformation to the unreduced part of the matrix, using a symmetric/Hermitian rank- $2k$ update of the form:

$$\text{sub}(A) := \text{sub}(A) - v w^* - w v^*.$$

The contents of a on exit are illustrated by the following examples with

$n = 5$ and $nb = 2$:

$$\begin{array}{cc} \text{if } uplo='U': & \text{if } uplo='L': \\ \left[\begin{array}{ccccc} a & a & a & v_4 & v_5 \\ & a & a & v_4 & v_5 \\ & & a & 1 & v_5 \\ & & & d & 1 \\ & & & & d \end{array} \right] & \left[\begin{array}{ccccc} d & & & & \\ 1 & d & & & \\ v_1 & 1 & a & & \\ v_1 & v_2 & a & a & \\ v_1 & v_2 & a & a & a \end{array} \right] \end{array}$$

where d denotes a diagonal element of the reduced matrix, a denotes an element of the original matrix that is unchanged, and v_i denotes an element of the vector defining $H(i)$.

Description

The `p?latrs` function solves a triangular system of equations $Ax = sb$, $A^T x = sb$ or $A^H x = sb$, where s is a scale factor set to prevent overflow. The description of the function will be extended in the future releases.

Input Parameters

<i>uplo</i>	Specifies whether the matrix A is upper or lower triangular. = 'U': Upper triangular = 'L': Lower triangular
<i>trans</i>	Specifies the operation applied to Ax . = 'N': Solve $Ax = s*b$ (no transpose) = 'T': Solve $A^T x = s*b$ (transpose) = 'C': Solve $A^H x = s*b$ (conjugate transpose), where s - is a scale factor
<i>diag</i>	Specifies whether or not the matrix A is unit triangular. = 'N': Non-unit triangular = 'U': Unit triangular
<i>normin</i>	Specifies whether <i>cnorm</i> has been set or not. = 'Y': <i>cnorm</i> contains the column norms on entry; = 'N': <i>cnorm</i> is not set on entry. On exit, the norms will be computed and stored in <i>cnorm</i> .
<i>n</i>	The order of the matrix A . $n \geq 0$
<i>a</i>	Array of size $lda * n$. Contains the triangular matrix A . If <i>uplo</i> = 'U', the leading n -by- n upper triangular part of the array <i>a</i> contains the upper triangular matrix, and the strictly lower triangular part of <i>a</i> is not referenced. If <i>uplo</i> = 'L', the leading n -by- n lower triangular part of the array <i>a</i> contains the lower triangular matrix, and the strictly upper triangular part of <i>a</i> is not referenced.

If *diag* = 'U', the diagonal elements of *a* are also not referenced and are assumed to be 1.

<i>ia, ja</i>	(global) The row and column indices in the global matrix <i>A</i> indicating the first row and the first column of the submatrix <i>A</i> , respectively.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .
<i>x</i>	Array of size <i>n</i> . On entry, the right hand side <i>b</i> of the triangular system.
<i>ix</i>	(global).The row index in the global matrix <i>X</i> indicating the first row of sub(<i>x</i>).
<i>jx</i>	(global) The column index in the global matrix <i>X</i> indicating the first column of sub(<i>X</i>).
<i>descx</i>	(global and local) Array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>X</i> .
<i>cnorm</i>	Array of size <i>n</i> . If <i>normin</i> = 'Y', <i>cnorm</i> is an input argument and <i>cnorm</i> [<i>j</i>] contains the norm of the off-diagonal part of the (<i>j</i> +1)-th column of the matrix <i>A</i> , <i>j</i> =0, 1, ..., <i>n</i> -1. If <i>trans</i> = 'N', <i>cnorm</i> [<i>j</i>] must be greater than or equal to the infinity-norm, and if <i>trans</i> = 'T' or 'C', <i>cnorm</i> [<i>j</i>] must be greater than or equal to the 1-norm.
<i>work</i>	(local). Temporary workspace.

Output Parameters

<i>x</i>	On exit, <i>x</i> is overwritten by the solution vector <i>x</i> .
<i>scale</i>	Array of size <i>lda</i> * <i>n</i> . The scaling factor <i>s</i> for the triangular system as described above. If <i>scale</i> = 0, the matrix <i>A</i> is singular or badly scaled, and the vector <i>x</i> is an exact or approximate solution to $Ax = 0$.
<i>cnorm</i>	If <i>normin</i> = 'N', <i>cnorm</i> is an output argument and <i>cnorm</i> [<i>j</i>] returns the 1-norm of the off-diagonal part of the (<i>j</i> +1)-th column of <i>A</i> , <i>j</i> =0, 1, ..., <i>n</i> -1.

p?latrz

Reduces an upper trapezoidal matrix to upper triangular form by means of orthogonal/unitary transformations.

Syntax

```
void pslatz (MKL_INT *m , MKL_INT *n , MKL_INT *l , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *tau , float *work );
```

```

void pdlatrz (MKL_INT *m , MKL_INT *n , MKL_INT *l , double *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , double *tau , double *work );

void pclatz (MKL_INT *m , MKL_INT *n , MKL_INT *l , MKL_Complex8 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *tau , MKL_Complex8 *work );

void pzlatrz (MKL_INT *m , MKL_INT *n , MKL_INT *l , MKL_Complex16 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *tau , MKL_Complex16 *work );

```

Include Files

- mkl_scalapack.h

Description

The `p?latrz` function reduces the m -by- n ($m \leq n$) real/complex upper trapezoidal matrix $\text{sub}(A) = [A(ia:ia+m-1, ja:ja+m-1)A(ia:ia+m-1, ja+n-l:ja+n-1)]$ to upper triangular form by means of orthogonal/unitary transformations.

The upper trapezoidal matrix $\text{sub}(A)$ is factored as

$$\text{sub}(A) = \begin{pmatrix} R & 0 \end{pmatrix} * Z,$$

where Z is an n -by- n orthogonal/unitary matrix and R is an m -by- m upper triangular matrix.

Input Parameters

m	(global) The number of rows in the distributed matrix $\text{sub}(A)$. $m \geq 0$.
n	(global) The number of columns in the distributed matrix $\text{sub}(A)$. $n \geq 0$.
l	(global) The number of columns of the distributed matrix $\text{sub}(A)$ containing the meaningful part of the Householder reflectors. $l > 0$.
a	(local) Pointer into the local memory to an array of size $lld\_a * LOCc(ja+n-1)$. On entry, the local pieces of the m -by- n distributed matrix $\text{sub}(A)$, which is to be factored.
ia	(global) The row index in the global matrix A indicating the first row of $\text{sub}(A)$.
ja	(global) The column index in the global matrix A indicating the first column of $\text{sub}(A)$.
$desca$	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix A .
$work$	(local) Workspace array of size $lwork$. $lwork \geq nq0 + \max(1, mp0)$, where

```

iroff = mod(ia-1, mb_a),
icoff = mod(ja-1, nb_a),
iarow = indxg2p(ia, mb_a, myrow, rsrc_a, nprow),
iacol = indxg2p(ja, nb_a, mycol, csrc_a, npcol),
mp0 = numroc(m+iroff, mb_a, myrow, iarow, nprow),
nq0 = numroc(n+icoff, nb_a, mycol, iacol, npcol),
numroc, indxg2p, and numroc are ScaLAPACK tool functions; myrow,
mycol, nprow, and npcol can be determined by calling the function
blacs_gridinfo.

```

Output Parameters

<i>a</i>	On exit, the leading m -by- m upper triangular part of sub(A) contains the upper triangular matrix R , and elements $n-l+1$ to n of the first m rows of sub(A), with the array <i>tau</i> , represent the orthogonal/unitary matrix Z as a product of m elementary reflectors.
<i>tau</i>	(local) Array of size $LOCr(ja+m-1)$. This array contains the scalar factors of the elementary reflectors. <i>tau</i> is tied to the distributed matrix A .

Application Notes

The factorization is obtained by Householder's method. The k -th transformation matrix, $Z(k)$, which is used (or, in case of complex functions, whose conjugate transpose is used) to introduce zeros into the $(m - k + 1)$ -th row of sub(A), is given in the form

$$Z(k) = \begin{bmatrix} I & 0 \\ 0 & T(k) \end{bmatrix},$$

where

$$T(k) = I - \tau u(k) u(k)', \quad u(k) = \begin{bmatrix} I \\ 0 \\ z(k) \end{bmatrix}$$

τ is a scalar and $z(k)$ is an $(n-m)$ -element vector. τ and $z(k)$ are chosen to annihilate the elements of the k -th row of sub(A). The scalar τ is returned in the k -th element of *tau*, indexed $k-1$, and the vector $u(k)$ in the k -th row of sub(A), such that the elements of $z(k)$ are in $A(k, m+1), \dots, A(k, n)$. The elements of R are returned in the upper triangular part of sub(A).

Z is given by

$$Z = Z(1) Z(2) \dots Z(m).$$

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

p?lauu2

Computes the product $U*U'$ or $L'*L$, where U and L are upper or lower triangular matrices (local unblocked algorithm).

Syntax

```
void pslauu2 (char *uplo , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca );

void pdlauu2 (char *uplo , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca );

void pclauu2 (char *uplo , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca );

void pzlauu2 (char *uplo , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca );
```

Include Files

- mkl_scalapack.h

Description

The p?lauu2 function computes the product $U*U'$ or $L'*L$, where the triangular factor U or L is stored in the upper or lower triangular part of the distributed matrix

$\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$.

If $uplo = 'U'$ or $'u'$, then the upper triangle of the result is stored, overwriting the factor U in $\text{sub}(A)$.

If $uplo = 'L'$ or $'l'$, then the lower triangle of the result is stored, overwriting the factor L in $\text{sub}(A)$.

This is the unblocked form of the algorithm, calling [BLAS Level 2 Routines](#). No communication is performed by this function, the matrix to operate on should be strictly local to one process.

Input Parameters

$uplo$	(global)
	Specifies whether the triangular factor stored in the <i>matrix</i> $\text{sub}(A)$ is upper or lower triangular:
	= U: upper triangular
	= L: lower triangular.
n	(global)
	The number of rows and columns to be operated on, that is, the order of the triangular factor U or L . $n \geq 0$.
a	(local)
	Pointer into the local memory to an array of size $lld\_a * LOCc(ja+n-1)$. On entry, the local pieces of the triangular factor U or L .
ia	(global)
	The row index in the global matrix A indicating the first row of $\text{sub}(A)$.
ja	(global)

The column index in the global matrix A indicating the first column of $\text{sub}(A)$.

desca

(global and local) array of size *dlen_*. The array descriptor for the distributed matrix A .

Output Parameters

a

(local)

On exit, if *uplo* = 'U', the upper triangle of the distributed matrix $\text{sub}(A)$ is overwritten with the upper triangle of the product $U*U'$; if *uplo* = 'L', the lower triangle of $\text{sub}(A)$ is overwritten with the lower triangle of the product $L'*L$.

See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

p?lauum

Computes the product $U*U'$ or $L'*L$, where U and L are upper or lower triangular matrices.

Syntax

```
void pslauum (char *uplo , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );
```

```
void pdlauum (char *uplo , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );
```

```
void pclauum (char *uplo , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );
```

```
void pzlauum (char *uplo , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );
```

Include Files

- `mkl_scalapack.h`

Description

The `p?lauum` function computes the product $U*U'$ or $L'*L$, where the triangular factor U or L is stored in the upper or lower triangular part of the matrix $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$.

If *uplo* = 'U' or 'u', then the upper triangle of the result is stored, overwriting the factor U in $\text{sub}(A)$. If *uplo* = 'L' or 'l', then the lower triangle of the result is stored, overwriting the factor L in $\text{sub}(A)$.

This is the blocked form of the algorithm, calling Level 3 PBLAS.

Input Parameters

uplo

(global)

Specifies whether the triangular factor stored in the matrix $\text{sub}(A)$ is upper or lower triangular:

= 'U': upper triangular

= 'L': lower triangular.

<i>n</i>	(global) The number of rows and columns to be operated on, that is, the order of the triangular factor <i>U</i> or <i>L</i> . $n \geq 0$.
<i>a</i>	(local) Pointer into the local memory to an array of size $lld\_a * LOCC(ja+n-1)$. On entry, the local pieces of the triangular factor <i>U</i> or <i>L</i> .
<i>ia</i>	(global) The row index in the global matrix <i>A</i> indicating the first row of sub(<i>A</i>).
<i>ja</i>	(global) The column index in the global matrix <i>A</i> indicating the first column of sub(<i>A</i>).
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> .

Output Parameters

<i>a</i>	(local) On exit, if <i>uplo</i> = 'U', the upper triangle of the distributed matrix sub(<i>A</i>) is overwritten with the upper triangle of the product $U*U$; if <i>uplo</i> = 'L', the lower triangle of sub(<i>A</i>) is overwritten with the lower triangle of the product $L*L$.

p?lawil

Forms the Wilkinson transform.

Syntax

```
void pslawil (MKL_INT *ii , MKL_INT *jj , MKL_INT *m , float *a , MKL_INT *desca ,
float *h44 , float *h33 , float *h43h34 , float *v );
```

```
void pdlawil (MKL_INT *ii , MKL_INT *jj , MKL_INT *m , double *a , MKL_INT *desca ,
double *h44 , double *h33 , double *h43h34 , double *v );
```

Include Files

- mkl_scalapack.h

Description

The p?lawil function gets the transform given by *h44*, *h33*, and *h43h34* into *v* starting at row *m*.

Input Parameters

<i>ii</i>	(global) Row owner of $h(m+2, m+2)$.
<i>jj</i>	(global)

	Column owner of $h(m+2, m+2)$.
m	(global) On entry, the location from where the transform starts (row m). Unchanged on exit.
a	(global) Array of size $ld_a * LOCc(n_a)$. On entry, the Hessenberg matrix. Unchanged on exit.
$desca$	(global and local) Array of size $dlen_$. The array descriptor for the distributed matrix A . Unchanged on exit.
$h43h34$	(global) These three values are for the double shift QR iteration. Unchanged on exit.

Output Parameters

v	(global) Array of size 3 that contains the transform on output.

See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

p?org2l/p?ung2l

Generates all or part of the orthogonal/unitary matrix Q from a QL factorization determined by p?geqlf (unblocked algorithm).

Syntax

```
void psorg2l (MKL_INT *m , MKL_INT *n , MKL_INT *k , float *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , float *tau , float *work , MKL_INT *lwork , MKL_INT *info );
void pdorg2l (MKL_INT *m , MKL_INT *n , MKL_INT *k , double *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , double *tau , double *work , MKL_INT *lwork , MKL_INT *info );
void pcung2l (MKL_INT *m , MKL_INT *n , MKL_INT *k , MKL_Complex8 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *tau , MKL_Complex8 *work , MKL_INT
*lwork , MKL_INT *info );
void pzung2l (MKL_INT *m , MKL_INT *n , MKL_INT *k , MKL_Complex16 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *tau , MKL_Complex16 *work , MKL_INT
*lwork , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The p?org2l/p?ung2l function generates an m -by- n real/complex distributed matrix Q denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal columns, which is defined as the last n columns of a product of k elementary reflectors of order m :

$Q = H(k)*\dots*H(2)*H(1)$ as returned by `p?geqlf`.

Input Parameters

m	(global) The number of rows in the distributed submatrix Q . $m \geq 0$.
n	(global) The number of columns in the distributed submatrix Q . $m \geq n \geq 0$.
k	(global) The number of elementary reflectors whose product defines the matrix Q . $n \geq k \geq 0$.
a	Pointer into the local memory to an array of size $lld\_a * LOCC(ja+n-1)$. On entry, the j -th column of the matrix stored in a must contain the vector that defines the elementary reflector $H(j)$, $ja+n-k \leq j \leq ja+n-1$, as returned by <code>p?geqlf</code> in the k columns of its <i>distributed matrix</i> argument $A(ia:*, ja+n-k:ja+n-1)$.
ia	(global) The row index in the global matrix A indicating the first row of sub(A).
ja	(global) The column index in the global matrix A indicating the first column of sub(A).
$desca$	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix A .
τ	(local) Array of size $LOCC(ja+n-1)$. $\tau[j]$ contains the scalar factor of the elementary reflector $H(j+1)$, $j = 0, 1, \dots, LOCC(ja+n-1)-1$, as returned by <code>p?geqlf</code> .
$work$	(local) Workspace array of size $lwork$.
$lwork$	(local or global) The size of the array $work$. $lwork$ is local input and must be at least $lwork \geq mpa0 + \max(1, nqa0)$, where $iroffa = \text{mod}(ia-1, mb\_a),$ $icoffa = \text{mod}(ja-1, nb\_a),$ $iarow = \text{indxg2p}(ia, mb\_a, myrow, rsrc\_a, nprow),$ $iacol = \text{indxg2p}(ja, nb\_a, mycol, csrc\_a, npcot),$ $mpa0 = \text{numroc}(m+iroffa, mb\_a, myrow, iarow, nprow),$ $nqa0 = \text{numroc}(n+icoffa, nb\_a, mycol, iacol, npcot).$

`indxg2p` and `numroc` are ScaLAPACK tool functions; *myrow*, *mycol*, *nprow*, and *npcol* can be determined by calling the function `blacs_gridinfo`.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

<i>a</i>	On exit, this array contains the local pieces of the <i>m</i> -by- <i>n</i> distributed matrix <i>Q</i> .
<i>work</i>	On exit, <i>work</i> [0] returns the minimal and optimal <i>lwork</i> .
<i>info</i>	(local). = 0: successful exit < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j</i> -1, had an illegal value, then <i>info</i> = - (<i>i</i> *100 + <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

*lwork , MKL_INT *info );
```

Include Files

- `mkl_scalapack.h`

Description

The `p?org2r/p?ung2r` function generates an m -by- n real/complex matrix Q denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal columns, which is defined as the first n columns of a product of k elementary reflectors of order m :

$$Q = H(1)*H(2)*...*H(k)$$

as returned by `p?geqrf`.

Input Parameters

m	(global) The number of rows in the distributed submatrix Q . $m \geq 0$.
n	(global) The number of columns in the distributed submatrix Q . $m \geq n \geq 0$.
k	(global) The number of elementary reflectors whose product defines the matrix Q . $n \geq k \geq 0$.
a	Pointer into the local memory to an array of size $ld_a * LOCC(ja+n-1)$ On entry, the j -th column of the matrix stored in a must contain the vector that defines the elementary reflector $H(j)$, $ja \leq j \leq ja+k-1$, as returned by <code>p?geqrf</code> in the k columns of its <i>distributed matrix</i> argument $A(ia:*, ja:ja+k-1)$.
ia	(global) The row index in the global matrix A indicating the first row of sub(A).
ja	(global) The column index in the global matrix A indicating the first column of sub(A).
$desca$	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix A .
τ	(local) Array of size $LOCC(ja+k-1)$. $\tau[j]$ contains the scalar factor of the elementary reflector $H(j+1)$, $j = 0, 1, \dots, LOCC(ja+k-1)-1$, as returned by <code>p?geqrf</code> . This array is tied to the distributed matrix A .
$work$	(local) Workspace array of size $lwork$.
$lwork$	(local or global) The size of the array $work$. $lwork$ is local input and must be at least $lwork \geq mpa0 + \max(1, nqa0)$, where

```
iroffa = mod(ia-1, mb_a , icoffa = mod(ja-1, nb_a),
iarow = indxg2p(ia, mb_a, myrow, rsrc_a, nprow),
iacol = indxg2p(ja, nb_a, mycol, csrc_a, npcot),
mpa0 = numroc(m+iroffa, mb_a, myrow, iarow, nprow),
nqa0 = numroc(n+icoffa, nb_a, mycol, iacol, npcot).

indxg2p and numroc are ScaLAPACK tool functions; myrow, mycol, nprow,
and npcot can be determined by calling the function blacs_gridinfo.
```

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by [pxerbla](#).

Output Parameters

<i>a</i>	On exit, this array contains the local pieces of the <i>m</i> -by- <i>n</i> distributed matrix <i>Q</i> .
<i>work</i>	On exit, <i>work</i> [0] returns the minimal and optimal <i>lwork</i> .
<i>info</i>	(local). = 0: successful exit < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j</i> -1, had an illegal value, then <i>info</i> = - (<i>i</i> *100 + <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

- mkl_scalapack.h

Description

The `p?orgr2/p?ungr2` function generates an m -by- n real/complex matrix Q denoting $A(ia:ia+m-1, ja:ja+n-1)$ with orthonormal rows, which is defined as the last m rows of a product of k elementary reflectors of order n

$Q = H(1)*H(2)*...*H(k)$ (for real flavors);

$Q = (H(1))^H*(H(2))^H*...(H(k))^H$ (for complex flavors) as returned by `p?gerqf`.

Input Parameters

m	(global) The number of rows in the distributed submatrix Q . $m \geq 0$.
n	(global) The number of columns in the distributed submatrix Q . $n \geq m \geq 0$.
k	(global) The number of elementary reflectors whose product defines the matrix Q . $m \geq k \geq 0$.
a	Pointer into the local memory to an array of size $lld\_a * LOCc(ja+n-1)$. On entry, the i -th row of the matrix stored in a must contain the vector that defines the elementary reflector $H(i)$, $ia+m-k \leq i \leq ia+m-1$, as returned by <code>p?gerqf</code> in the k rows of its <i>distributed matrix</i> argument $A(ia+m-k:ia+m-1, ja:*)$.
ia	(global) The row index in the global matrix A indicating the first row of $sub(A)$.
ja	(global) The column index in the global matrix A indicating the first column of $sub(A)$.
$desca$	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix A .
tau	(local) Array of size $LOCr(ja+m-1)$. $tau[j]$ contains the scalar factor of the elementary reflectors $H(j+1)$, $j = 0, 1, \dots, LOCr(ja+m-1)-1$, as returned by <code>p?gerqf</code> . This array is tied to the distributed matrix A .
$work$	(local) Workspace array of size $lwork$.

lwork (local or global)

The size of the array *work*.

lwork is local input and must be at least $lwork \geq nqa0 + \max(1, mpa0)$, where $iroffa = \text{mod}(ia-1, mb\_a)$, $icoffa = \text{mod}(ja-1, nb\_a)$, $iarow = \text{indxg2p}(ia, mb\_a, myrow, rsrc\_a, nprow)$, $iacol = \text{indxg2p}(ja, nb\_a, mycol, csrc\_a, npcrow)$, $mpa0 = \text{numroc}(m+iroffa, mb\_a, myrow, iarow, nprow)$, $nqa0 = \text{numroc}(n+icoffa, nb\_a, mycol, iacol, npcrow)$.

indxg2p and numroc are ScaLAPACK tool functions; *myrow*, *mycol*, *nprow*, and *npcol* can be determined by calling the function `blacs_gridinfo`.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by `pxerbla`.

Output Parameters

a On exit, this array contains the local pieces of the *m*-by-*n* distributed matrix *Q*.

work On exit, *work*[0] returns the minimal and optimal *lwork*.

info (local)

- = 0: successful exit
- < 0: if the *i*-th argument is an array and the *j*-th entry, indexed *j*-1, had an illegal value,
then *info* = - (*i**100 + *j*),
- if the *i*-th argument is a scalar and had an illegal value,
then *info* = -*i*.

Description

The `p?orm2l/p?unm2l` function overwrites the general real/complex m -by- n distributed matrix sub(C)= $C(ic:ic+m-1,jc:jc+n-1)$ with

$Q*\text{sub}(C)$ if $side = 'L'$ and $trans = 'N'$, or

$Q^T*\text{sub}(C) / Q^H*\text{sub}(C)$ if $side = 'L'$ and $trans = 'T'$ (for real flavors) or $trans = 'C'$ (for complex flavors), or

$\text{sub}(C)*Q$ if $side = 'R'$ and $trans = 'N'$, or

$\text{sub}(C)*Q^T / \text{sub}(C)*Q^H$ if $side = 'R'$ and $trans = 'T'$ (for real flavors) or $trans = 'C'$ (for complex flavors).

where Q is a real orthogonal or complex unitary distributed matrix defined as the product of k elementary reflectors

$Q = H(k)*...*H(2)*H(1)$ as returned by `p?geqlf`. Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

<i>side</i>	(global) = 'L': apply Q or Q^T for real flavors (Q^H for complex flavors) from the left, = 'R': apply Q or Q^T for real flavors (Q^H for complex flavors) from the right.
<i>trans</i>	(global) = 'N': apply Q (no transpose) = 'T': apply Q^T (transpose, for real flavors) = 'C': apply Q^H (conjugate transpose, for complex flavors)
<i>m</i>	(global) The number of rows in the distributed matrix sub(C). $m \geq 0$.
<i>n</i>	(global) The number of columns in the distributed matrix sub(C). $n \geq 0$.
<i>k</i>	(global) The number of elementary reflectors whose product defines the matrix Q . If $side = 'L'$, $m \geq k \geq 0$;

if $side = 'R', n \geq k \geq 0$.

a

(local)

Pointer into the local memory to an array of size $lld\_a * LOCc(ja+k-1)$.

On entry, the j -th row of the matrix stored in *a* must contain the vector that defines the elementary reflector $H(j)$, $ja \leq j \leq ja+k-1$, as returned by [p?geqlf](#) in the k columns of its distributed matrix argument $A(ia:*, ja:ja+k-1)$. The argument $A(ia:*, ja:ja+k-1)$ is modified by the function but restored on exit.

If $side = 'L', lld\_a \geq \max(1, LOCr(ia+m-1))$,

if $side = 'R', lld\_a \geq \max(1, LOCr(ia+n-1))$.

ia

(global)

The row index in the global matrix *A* indicating the first row of sub(*A*).

ja

(global)

The column index in the global matrix *A* indicating the first column of sub(*A*).

desca

(global and local) array of size *dlen_*. The array descriptor for the distributed matrix *A*.

tau

(local)

Array of size $LOCc(ja+n-1)$. $tau[j]$ contains the scalar factor of the elementary reflector $H(j+1)$, $j = 0, 1, \dots, LOCc(ja+n-1)-1$, as returned by [p?geqlf](#). This array is tied to the distributed matrix *A*.

c

(local)

Pointer into the local memory to an array of size $lld\_c * LOCc(jc+n-1)$. On entry, the local pieces of the distributed matrix sub(*C*).

ic

(global)

The row index in the global matrix *C* indicating the first row of sub(*C*).

jc

(global)

The column index in the global matrix *C* indicating the first column of sub(*C*).

descc

(global and local) array of size *dlen_*. The array descriptor for the distributed matrix *C*.

work

(local)

Workspace array of size *lwork*.

On exit, $work(1)$ returns the minimal and optimal *lwork*.

lwork

(local or global)

The size of the array *work*.

lwork is local input and must be at least

if $side = 'L', lwork \geq mpc0 + \max(1, nqc0)$,

```
if side = 'R', lwork ≥ nqc0 + max(max(1, mpc0), numroc(numroc(n
+icoffc, nb_a, 0, 0, npcol), nb_a, 0, 0, lcmq)),
```

where

```
lcmq = lcm/npcol,
lcm = iclm(nprow, npcol),
iroffc = mod(ic-1, mb_c),
icoffc = mod(jc-1, nb_c),
icrow = indxg2p(ic, mb_c, myrow, rsrc_c, nprow),
iccol = indxg2p(jc, nb_c, mycol, csrc_c, npcol),
Mqc0 = numroc(m+icoffc, nb_c, mycol, icrow, nprow),
Npc0 = numroc(n+iroffc, mb_c, myrow, iccol, npcol),
ilcm, indxg2p, and numroc are ScaLAPACK tool functions; myrow, mycol,
nprow, and npcol can be determined by calling the function
blacs_gridinfo.
```

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by [pxerbla](#).

Output Parameters

c	On exit, c is overwritten by $Q*\text{sub}(C)$, or $Q^T*\text{sub}(C)/Q^H*\text{sub}(C)$, or $\text{sub}(C)*Q$, or $\text{sub}(C)*Q^T / \text{sub}(C)*Q^H$
$work$	On exit, $work[0]$ returns the minimal and optimal $lwork$.
$info$	(local) = 0: successful exit < 0: if the i -th argument is an array and the j -th entry, indexed $j-1$, had an illegal value, then $info = -(i*100 + j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

NOTE

The distributed submatrices $A(ia:*, ja:*)$ and $C(ic:ic+m-1, jc:jc+n-1)$ must verify some alignment properties, namely the following expressions should be true:

If $side = 'L'$, ($mb\_a == mb\_c$ && $iroffa == iroffc$ && $iarow == icrow$)

If $side = 'R'$, ($mb\_a == nb\_c$ && $iroffa == iroffc$).

Description

The p?orm2r/p?unm2r function overwrites the general real/complex m -by- n distributed matrix sub(C) = $C(ic:ic+m-1, jc:jc+n-1)$ with

$Q^T \text{sub}(C)$ if $side = 'L'$ and $trans = 'N'$, or

$Q^T \text{sub}(C) / Q^H \text{sub}(C)$ if $side = 'L'$ and $trans = 'T'$ (for real flavors) or $trans = 'C'$ (for complex flavors), or

$\text{sub}(C) * Q$ if $side = 'R'$ and $trans = 'N'$, or

$\text{sub}(C) * Q^T / \text{sub}(C) * Q^H$ if $side = 'R'$ and $trans = 'T'$ (for real flavors) or $trans = 'C'$ (for complex flavors).

where Q is a real orthogonal or complex unitary matrix defined as the product of k elementary reflectors

$Q = H(k) * \dots * H(2) * H(1)$ as returned by p?geqrf. Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

<i>side</i>	(global)
	= 'L': apply Q or Q^T for real flavors (Q^H for complex flavors) from the left,
	= 'R': apply Q or Q^T for real flavors (Q^H for complex flavors) from the right.
<i>trans</i>	(global)
	= 'N': apply Q (no transpose)

	= 'T': apply Q^T (transpose, for real flavors)
	= 'C': apply Q^H (conjugate transpose, for complex flavors)
m	(global) The number of rows in the distributed matrix $\text{sub}(C)$. $m \geq 0$.
n	(global) The number of columns in the distributed matrix $\text{sub}(C)$. $n \geq 0$.
k	(global) The number of elementary reflectors whose product defines the matrix Q . If $\text{side} = \text{'L'}$, $m \geq k \geq 0$; if $\text{side} = \text{'R'}$, $n \geq k \geq 0$.
a	(local) Pointer into the local memory to an array of size $\text{lld\_a} * \text{LOCc}(ja+k-1)$. On entry, the j -th column of the matrix stored in a must contain the vector that defines the elementary reflector $H(j)$, $ja \leq j \leq ja+k-1$, as returned by p?geqrf in the k columns of its distributed matrix argument $A(ia:*, ja:ja+k-1)$. The argument $A(ia:*, ja:ja+k-1)$ is modified by the function but restored on exit. If $\text{side} = \text{'L'}$, $\text{lld\_a} \geq \max(1, \text{LOCr}(ia+m-1))$, if $\text{side} = \text{'R'}$, $\text{lld\_a} \geq \max(1, \text{LOCr}(ia+n-1))$.
ia	(global) The row index in the global matrix A indicating the first row of $\text{sub}(A)$.
ja	(global) The column index in the global matrix A indicating the first column of $\text{sub}(A)$.
$desca$	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix A .
τ	(local) Array of size $\text{LOCc}(ja+k-1)$. $\tau[j]$ contains the scalar factor of the elementary reflector $H(j+1)$, $j = 0, 1, \dots, \text{LOCc}(ja+k-1)-1$, as returned by p?geqrf . This array is tied to the distributed matrix A .
c	(local) Pointer into the local memory to an array of size $\text{lld\_c} * \text{LOCc}(jc+n-1)$. On entry, the local pieces of the distributed matrix $\text{sub}(C)$.
ic	(global) The row index in the global matrix C indicating the first row of $\text{sub}(C)$.
jc	(global)

The column index in the global matrix *C* indicating the first column of *sub(C)*.

desc (global and local) array of size *dlen_*.

The array descriptor for the distributed matrix *C*.

work (local)

Workspace array of size *lwork*.

lwork (local or global)

The size of the array *work*.

lwork is local input and must be at least

if *side* = 'L', $lwork \geq mpc0 + \max(1, nqc0)$,

if *side* = 'R', $lwork \geq nqc0 + \max(\max(1, mpc0), \text{numroc}(\text{numroc}(n + icoffc, nb\_a, 0, 0, npc0), nb\_a, 0, 0, lcmq))$,

where

$lcmq = lcm / npc0$,

$lcm = iclm(nprow, npc0)$,

$iroffc = \text{mod}(ic-1, mb\_c)$,

$icoffc = \text{mod}(jc-1, nb\_c)$,

$icrow = \text{indxg2p}(ic, mb\_c, myrow, rsrc\_c, nprow)$,

$iccol = \text{indxg2p}(jc, nb\_c, mycol, csrc\_c, npc0)$,

$Mqc0 = \text{numroc}(m + icoffc, nb\_c, mycol, icrow, nprow)$,

$Npc0 = \text{numroc}(n + iroffc, mb\_c, myrow, iccol, npc0)$,

ilcm, *indxg2p* and *numroc* are ScaLAPACK tool functions; *myrow*, *mycol*, *nprow*, and *npc0* can be determined by calling the function *blacs_gridinfo*.

If *lwork* = -1, then *lwork* is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by *pxerbla*.

Output Parameters

c On exit, *c* is overwritten by $Q \cdot \text{sub}(C)$, or $Q^T \cdot \text{sub}(C) / Q^H \cdot \text{sub}(C)$, or $\text{sub}(C) \cdot Q$, or $\text{sub}(C) \cdot Q^T / \text{sub}(C) \cdot Q^H$

work On exit, *work*[0] returns the minimal and optimal *lwork*.

info (local)

= 0: successful exit

< 0: if the *i*-th argument is an array and the *j*-th entry, indexed *j*-1, had an illegal value,

then *info* = - (*i**100 + *j*),

if the *i*-th argument is a scalar and had an illegal value,

then *info* = -*i*.

NOTE

The distributed submatrices $A(ia:*, ja:*)$ and $C(ic:ic+m-1, jc:jc+n-1)$ must verify some alignment properties, namely the following expressions should be true:

If *side* = 'L', (*mb_a* == *mb_c*) && (*iroffa* == *iroffc*) && (*iarow* == *icrow*).

If *side* = 'R', (*mb_a* == *nb_c*) && (*iroffa* == *iroffc*).

Description

The p?orml2/p?unml2 function overwrites the general real/complex *m*-by-*n* distributed matrix sub(*C*)=*C*(*ic:ic+m-1, jc:jc+n-1*) with

$Q \cdot \text{sub}(C)$ if *side* = 'L' and *trans* = 'N', or

$Q^T \cdot \text{sub}(C)$ / $Q^H \cdot \text{sub}(C)$ if *side* = 'L' and *trans* = 'T' (for real flavors) or *trans* = 'C' (for complex flavors), or

$\text{sub}(C) \cdot Q$ if *side* = 'R' and *trans* = 'N', or

$\text{sub}(C) \cdot Q^T$ / $\text{sub}(C) \cdot Q^H$ if *side* = 'R' and *trans* = 'T' (for real flavors) or *trans* = 'C' (for complex flavors).

where *Q* is a real orthogonal or complex unitary distributed matrix defined as the product of *k* elementary reflectors

$Q = H(k) * \dots * H(2) * H(1)$ (for real flavors)

$Q = (H(k))^H * \dots * (H(2))^H * (H(1))^H$ (for complex flavors)

as returned by `p?gelqf`. Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

<i>side</i>	(global) = 'L': apply Q or Q^T for real flavors (Q^H for complex flavors) from the left, = 'R': apply Q or Q^T for real flavors (Q^H for complex flavors) from the right.
<i>trans</i>	(global) = 'N': apply Q (no transpose) = 'T': apply Q^T (transpose, for real flavors) = 'C': apply Q^H (conjugate transpose, for complex flavors)
<i>m</i>	(global) The number of rows in the distributed matrix $\text{sub}(C)$. $m \geq 0$.
<i>n</i>	(global) The number of columns in the distributed matrix $\text{sub}(C)$. $n \geq 0$.
<i>k</i>	(global) The number of elementary reflectors whose product defines the matrix Q . If $side = 'L'$, $m \geq k \geq 0$; if $side = 'R'$, $n \geq k \geq 0$.
<i>a</i>	(local) Pointer into the local memory to an array of size $lld\_a * LOCC(ja+m-1)$ if $side='L'$, $lld\_a * LOCC(ja+n-1)$ if $side='R'$, where $lld\_a \geq \max(1, LOCr(ia+k-1))$. On entry, the i -th row of the matrix stored in a must contain the vector that defines the elementary reflector $H(i)$, $ia \leq i \leq ia+k-1$, as returned by <code>p?gelqf</code> in the k rows of its distributed matrix argument $A(ia:ia+k-1, ja:*)$. The argument $A(ia:ia+k-1, ja:*)$ is modified by the function but restored on exit.
<i>ia</i>	(global) The row index in the global matrix A indicating the first row of $\text{sub}(A)$.
<i>ja</i>	(global) The column index in the global matrix A indicating the first column of $\text{sub}(A)$.
<i>desca</i>	(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix A .

<i>tau</i>	(local) Array of size $LOCc(ia+k-1)$. <i>tau</i> [<i>i</i>] contains the scalar factor of the elementary reflector $H(i+1)$, $i = 0, 1, \dots, LOCc(ja+k-1)-1$, as returned by p?gelqf . This array is tied to the distributed matrix <i>A</i> .
<i>c</i>	(local) Pointer into the local memory to an array of size $lld\_c * LOCc(jc+n-1)$. On entry, the local pieces of the distributed matrix sub(<i>C</i>).
<i>ic</i>	(global) The row index in the global matrix <i>C</i> indicating the first row of sub(<i>C</i>).
<i>jc</i>	(global) The column index in the global matrix <i>C</i> indicating the first column of sub(<i>C</i>).
<i>desc</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>C</i> .
<i>work</i>	(local) Workspace array of size <i>lwork</i> .
<i>lwork</i>	(local or global) The size of the array <i>work</i> . <i>lwork</i> is local input and must be at least <pre> if side = 'L', lwork ≥ mqc0 + max(max(1, npc0), numroc(numroc(m +icoffc, mb_a, 0, 0, nprow), mb_a, 0, 0, lcmp)), if side = 'R', lwork ≥ npc0 + max(1, mqc0), </pre> where <pre> lcmp = lcm / nprow, lcm = iclm(nprow, npc0), iroffc = mod(ic-1, mb_c), icoffc = mod(jc-1, nb_c), icrow = indxg2p(ic, mb_c, myrow, rsrc_c, nprow), iccol = indxg2p(jc, nb_c, mycol, csrc_c, npc0), Mpc0 = numroc(m+icoffc, mb_c, mycol, icrow, nprow), Nqc0 = numroc(n+iroffc, nb_c, myrow, iccol, npc0), </pre> <i>iclm</i> , <i>indxg2p</i> and <i>numroc</i> are ScaLAPACK tool functions; <i>myrow</i> , <i>mycol</i> , <i>nprow</i> , and <i>npcol</i> can be determined by calling the function <i>blacs_gridinfo</i> . If <i>lwork</i> = -1, then <i>lwork</i> is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla .

Output Parameters

<i>c</i>	On exit, <i>c</i> is overwritten by $Q \cdot \text{sub}(C)$, or $Q^T \cdot \text{sub}(C)$, or $Q^H \cdot \text{sub}(C)$, or $\text{sub}(C) \cdot Q$, or $\text{sub}(C) \cdot Q^T$ / $\text{sub}(C) \cdot Q^H$
<i>work</i>	On exit, <i>work</i> [0] returns the minimal and optimal <i>lwork</i> .
<i>info</i>	(local) = 0: successful exit < 0: if the <i>i</i> -th argument is an array and the <i>j</i> -th entry, indexed <i>j</i> -1, had an illegal value, then <i>info</i> = - (<i>i</i> *100 + <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

NOTE

The distributed submatrices $A(\text{ia}:\text{*, } \text{ja}:\text{*})$ and $C(\text{ic}:\text{ic}+\text{m}-1, \text{jc}:\text{jc}+\text{n}-1)$ must verify some alignment properties, namely the following expressions should be true:

If *side* = 'L', (*nb_a* == *mb_c* && *icoffa* == *iroffc*)

If *side* = 'R', (*nb_a* == *nb_c* && *icoffa* == *icoffc* && *iacol* == *iccol*).

Description

The `p?ormr2/p?unmr2` function overwrites the general real/complex m -by- n distributed matrix sub(C)= $C(ic:ic+m-1, jc:jc+n-1)$ with

$Q*\text{sub}(C)$ if $side = 'L'$ and $trans = 'N'$, or

$Q^T*\text{sub}(C) / Q^H*\text{sub}(C)$ if $side = 'L'$ and $trans = 'T'$ (for real flavors) or $trans = 'C'$ (for complex flavors), or

$\text{sub}(C)*Q$ if $side = 'R'$ and $trans = 'N'$, or

$\text{sub}(C)*Q^T / \text{sub}(C)*Q^H$ if $side = 'R'$ and $trans = 'T'$ (for real flavors) or $trans = 'C'$ (for complex flavors).

where Q is a real orthogonal or complex unitary distributed matrix defined as the product of k elementary reflectors

$Q = H(1)*H(2)*...*H(k)$ (for real flavors)

$Q = (H(1))^H*(H(2))^H*...*(H(k))^H$ (for complex flavors)

as returned by `p?gerqf`. Q is of order m if $side = 'L'$ and of order n if $side = 'R'$.

Input Parameters

<i>side</i>	(global) = 'L': apply Q or Q^T for real flavors (Q^H for complex flavors) from the left, = 'R': apply Q or Q^T for real flavors (Q^H for complex flavors) from the right.
<i>trans</i>	(global) = 'N': apply Q (no transpose) = 'T': apply Q^T (transpose, for real flavors) = 'C': apply Q^H (conjugate transpose, for complex flavors)
<i>m</i>	(global) The number of rows in the distributed matrix sub(C). $m \geq 0$.
<i>n</i>	(global) The number of columns in the distributed matrix sub(C). $n \geq 0$.
<i>k</i>	(global) The number of elementary reflectors whose product defines the matrix Q . If $side = 'L'$, $m \geq k \geq 0$; if $side = 'R'$, $n \geq k \geq 0$.
<i>a</i>	(local) Pointer into the local memory to an array of size $lld\_a * LOCC(ja+m-1)$ if $side='L'$, $lld\_a * LOCC(ja+n-1)$ if $side='R'$,

where $lld\_a \geq \max(1, LOCr(ia+k-1))$.

On entry, the i -th row of the matrix stored in *a* must contain the vector that defines the elementary reflector $H(i)$, $ia \leq i \leq ia+k-1$, as returned by [p?gerqf](#) in the k rows of its distributed matrix argument $A(ia:ia+k-1, ja:*)$.

The argument $A(ia:ia+k-1, ja:*)$ is modified by the function but restored on exit.

ia (global)

The row index in the global matrix A indicating the first row of sub(A).

ja (global)

The column index in the global matrix A indicating the first column of sub(A).

desca (global and local) array of size *dlen_*. The array descriptor for the distributed matrix A .

tau (local)

Array of size $LOCc(ia+k-1)$. $tau[j]$ contains the scalar factor of the elementary reflector $H(j+1)$, $j = 0, 1, \dots, LOCc(ja+k-1)-1$, as returned by [p?gerqf](#). This array is tied to the distributed matrix A .

c (local)

Pointer into the local memory to an array of size $lld\_c * LOCc(jc+n-1)$. On entry, the local pieces of the distributed matrix sub (C).

ic (global)

The row index in the global matrix C indicating the first row of sub(C).

jc (global)

The column index in the global matrix C indicating the first column of sub(C).

descc (global and local) array of size *dlen_*. The array descriptor for the distributed matrix C .

work (local)

Workspace array of size *lwork*.

lwork (local or global)

The size of the array *work*.

lwork is local input and must be at least

if *side* = 'L', $lwork \geq mpc0 + \max(\max(1, nqc0), \text{numroc}(\text{numroc}(m + iroffc, mb\_a, 0, 0, nprow), mb\_a, 0, 0, lcm p)),$

if *side* = 'R', $lwork \geq nqc0 + \max(1, mpc0),$

where $lcmp = lcm/nprow,$

$lcm = iclm(nprow, npc0l),$

```

iroffc = mod(ic-1, mb_c),
icoffc = mod(jc-1, nb_c),
icrow = indxg2p(ic, mb_c, myrow, rsrc_c, nprow),
iccol = indxg2p(jc, nb_c, mycol, csrc_c, npcol),
Mpc0 = numroc(m+iroffc, mb_c, myrow, icrow, nprow),
Nqc0 = numroc(n+icoffc, nb_c, mycol, iccol, npcol),
ilcm, indxg2p and numroc are ScaLAPACK tool functions; myrow, mycol,
nprow, and npcol can be determined by calling the function
blacs_gridinfo.

```

If $lwork = -1$, then $lwork$ is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by [pxerbla](#).

Output Parameters

c	On exit, c is overwritten by $Q \cdot \text{sub}(C)$, or $Q^T \cdot \text{sub}(C) / Q^H \cdot \text{sub}(C)$, or $\text{sub}(C) \cdot Q$, or $\text{sub}(C) \cdot Q^T / \text{sub}(C) \cdot Q^H$
$work$	On exit, $work[0]$ returns the minimal and optimal $lwork$.
$info$	(local) = 0: successful exit < 0: if the i -th argument is an array and the j -th entry, indexed $j-1$, had an illegal value, then $info = - (i \cdot 100 + j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$.

NOTE

The distributed submatrices $A(ia:*, ja:*)$ and $C(ic:ic+m-1, jc:jc+n-1)$ must verify some alignment properties, namely the following expressions should be true:

If $side = 'L'$, $(nb\_a == mb\_c) \ \&\& \ (icoffa == iroffc)$.

If $side = 'R'$, $(nb\_a == nb\_c) \ \&\& \ (icoffa == icoffc) \ \&\& \ (iacol == iccol)$.

Description

The `p?pbtrsv` function solves a banded triangular system of linear equations

$$A(1:n, ja:ja+n-1) * X = B(jb:jb+n-1, 1:nrhs)$$

or

$$A(1:n, ja:ja+n-1)^T * X = B(jb:jb+n-1, 1:nrhs) \text{ for real flavors,}$$

$$A(1:n, ja:ja+n-1)^H * X = B(jb:jb+n-1, 1:nrhs) \text{ for complex flavors,}$$

where $A(1:n, ja:ja+n-1)$ is a banded triangular matrix factor produced by the Cholesky factorization code `p?pbtrf` and is stored in $A(1:n, ja:ja+n-1)$ and af . The matrix stored in $A(1:n, ja:ja+n-1)$ is either upper or lower triangular according to `uplo`.

The function `p?pbtrf` must be called first.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

`uplo` (global) Must be 'U' or 'L'.
If `uplo` = 'U', upper triangle of $A(1:n, ja:ja+n-1)$ is stored;
If `uplo` = 'L', lower triangle of $A(1:n, ja:ja+n-1)$ is stored.

<i>trans</i>	(global) Must be 'N' or 'T' or 'C'. If <i>trans</i> = 'N', solve with $A(1:n, ja:ja+n-1)$; If <i>trans</i> = 'T' or 'C' for real flavors, solve with $A(1:n, ja:ja+n-1)^T$. If <i>trans</i> = 'C' for complex flavors, solve with conjugate transpose $(A(1:n, ja:ja+n-1))^H$.
<i>n</i>	(global) The number of rows and columns to be operated on, that is, the order of the distributed submatrix $A(1:n, ja:ja+n-1)$. $n \geq 0$.
<i>bw</i>	(global) The number of subdiagonals in 'L' or 'U', $0 \leq bw \leq n-1$.
<i>nrhs</i>	(global) The number of right hand sides; the number of columns of the distributed submatrix $B(jb:jb+n-1, 1:nrhs)$; $nrhs \geq 0$.
<i>a</i>	(local) Pointer into the local memory to an array with the first size $lld\_a \geq (bw + 1)$, stored in <i>desca</i>. On entry, this array contains the local pieces of the n-by-n symmetric banded distributed Cholesky factor L or $L^T * A(1:n, ja:ja+n-1)$. This local portion is stored in the packed banded format used in LAPACK. See the <i>Application Notes</i> below and the ScaLAPACK manual for more detail on the format of distributed matrices.
<i>ja</i>	(global) The index in the global in the global matrix A that points to the start of the matrix to be operated on (which may be either all of A or a submatrix of A).
<i>desca</i>	(global and local) array of size <i>dlen_</i>. The array descriptor for the distributed matrix A. If 1D type (<i>dtype_a</i> = 501), then $dlen \geq 7$; If 2D type (<i>dtype_a</i> = 1), then $dlen \geq 9$. Contains information on mapping of A to memory. (See ScaLAPACK manual for full description and options.)
<i>b</i>	(local) Pointer into the local memory to an array of local lead size $lld\_b \geq nb$. On entry, this array contains the local pieces of the right hand sides $B(jb:jb+n-1, 1:nrhs)$.
<i>ib</i>	(global) The row index in the global matrix B that points to the first row of the matrix to be operated on (which may be either all of B or a submatrix of B).
<i>descb</i>	(global and local) array of size <i>dlen_</i>. The array descriptor for the distributed matrix B.

If 1D type (*dtype_b* = 502), then *dlen* ≥ 7;

If 2D type (*dtype_b* = 1), then *dlen* ≥ 9.

Contains information on mapping of *B* to memory. Please, see ScaLAPACK manual for full description and options.

laf

(local)

The size of user-input auxiliary fill-in space *af*. Must be $laf \geq (nb + 2*bw) * bw$. If *laf* is not large enough, an error code will be returned and the minimum acceptable size will be returned in *af*[0].

work

(local)

The array *work* is a temporary workspace array of size *lwork*. This space may be overwritten in between function calls.

lwork

(local or global) The size of the user-input workspace *work*, must be at least $lwork \geq bw * nrhs$. If *lwork* is too small, the minimal acceptable size will be returned in *work*[0] and an error code is returned.

Output Parameters

af

(local)

The array *af* is of size *laf*. It contains auxiliary fill-in space. The fill-in space is created in a call to the factorization function `p?pbtrf` and is stored in *af*. If a linear system is to be solved using `p?pbtrs` after the factorization function, *af* must not be altered after the factorization.

b

On exit, this array contains the local piece of the solutions distributed matrix *X*.

work[0]

On exit, *work*[0] contains the minimum value of *lwork*.

info

(local)

= 0: successful exit

< 0: if the *i*-th argument is an array and the *j*-th entry, indexed *j*-1, had an illegal value,

then $info = -(i*100 + j)$,

if the *i*-th argument is a scalar and had an illegal value,

then $info = -i$.

Application Notes

If the factorization function and the solve function are to be called separately to solve various sets of right-hand sides using the same coefficient matrix, the auxiliary space *af* must not be altered between calls to the factorization function and the solve function.

The best algorithm for solving banded and tridiagonal linear systems depends on a variety of parameters, especially the bandwidth. Currently, only algorithms designed for the case $N/P \gg bw$ are implemented. These algorithms go by many names, including Divide and Conquer, Partitioning, domain decomposition-type, etc.

The Divide and Conquer algorithm assumes the matrix is narrowly banded compared with the number of equations. In this situation, it is best to distribute the input matrix A one-dimensionally, with columns atomic and rows divided amongst the processes. The basic algorithm divides the banded matrix up into P pieces with one stored on each processor, and then proceeds in 2 phases for the factorization or 3 for the solution of a linear system.

1. **Local Phase** : The individual pieces are factored independently and in parallel. These factors are applied to the matrix creating fill-in, which is stored in a non-inspectable way in auxiliary space af . Mathematically, this is equivalent to reordering the matrix A as PAP^T and then factoring the principal leading submatrix of size equal to the sum of the sizes of the matrices factored on each processor. The factors of these submatrices overwrite the corresponding parts of A in memory.
2. **Reduced System Phase** : A small ($bw*(P-1)$) system is formed representing interaction of the larger blocks and is stored (as are its factors) in the space af . A parallel Block Cyclic Reduction algorithm is used. For a linear system, a parallel front solve followed by an analogous backsolve, both using the structure of the factored matrix, are performed.
3. **Back Substitution Phase**: For a linear system, a local backsubstitution is performed on each processor in parallel.

p?pttrsv

Solves a single triangular linear system via frontsolve or backsolve where the triangular matrix is a factor of a tridiagonal matrix computed by p?pttrf.

Syntax

```
void pspttrsv (char *uplo , MKL_INT *n , MKL_INT *nrhs , float *d , float *e , MKL_INT
*ja , MKL_INT *desca , float *b , MKL_INT *ib , MKL_INT *descb , float *af , MKL_INT
*laf , float *work , MKL_INT *lwork , MKL_INT *info );
```

```
void pdpttrsv (char *uplo , MKL_INT *n , MKL_INT *nrhs , double *d , double *e ,
MKL_INT *ja , MKL_INT *desca , double *b , MKL_INT *ib , MKL_INT *descb , double *af ,
MKL_INT *laf , double *work , MKL_INT *lwork , MKL_INT *info );
```

```
void pcpttrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *nrhs , float *d ,
MKL_Complex8 *e , MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *b , MKL_INT *ib ,
MKL_INT *descb , MKL_Complex8 *af , MKL_INT *laf , MKL_Complex8 *work , MKL_INT
*lwork , MKL_INT *info );
```

```
void pzpttrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *nrhs , double *d ,
MKL_Complex16 *e , MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *b , MKL_INT *ib ,
MKL_INT *descb , MKL_Complex16 *af , MKL_INT *laf , MKL_Complex16 *work , MKL_INT
*lwork , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The p?pttrsv function solves a tridiagonal triangular system of linear equations

$$A(1:n, ja:ja+n-1) * X = B(jb:jb+n-1, 1:nrhs)$$

or

$$A(1:n, ja:ja+n-1)^T * X = B(jb:jb+n-1, 1:nrhs) \text{ for real flavors,}$$

$A(1:n, ja:ja+n-1)^H X = B(jb:jb+n-1, 1:nrhs)$ for complex flavors,

where $A(1:n, ja:ja+n-1)$ is a tridiagonal triangular matrix factor produced by the Cholesky factorization code `p?pttrf` and is stored in $A(1:n, ja:ja+n-1)$ and *af*. The matrix stored in $A(1:n, ja:ja+n-1)$ is either upper or lower triangular according to *uplo*.

The function `p?pttrf` must be called first.

Input Parameters

<i>uplo</i>	(global) Must be 'U' or 'L'. If <i>uplo</i> = 'U', upper triangle of $A(1:n, ja:ja+n-1)$ is stored; If <i>uplo</i> = 'L', lower triangle of $A(1:n, ja:ja+n-1)$ is stored.
<i>trans</i>	(global) Must be 'N' or 'C'. If <i>trans</i> = 'N', solve with $A(1:n, ja:ja+n-1)$; If <i>trans</i> = 'C' (for complex flavors), solve with conjugate transpose $(A(1:n, ja:ja+n-1))^H$.
<i>n</i>	(global) The number of rows and columns to be operated on, that is, the order of the distributed submatrix $A(1:n, ja:ja+n-1)$. $n \geq 0$.
<i>nrhs</i>	(global) The number of right hand sides; the number of columns of the distributed submatrix $B(jb:jb+n-1, 1:nrhs)$; $nrhs \geq 0$.
<i>d</i>	(local) Pointer to the local part of the global vector storing the main diagonal of the matrix; must be of size $\geq nb\_a$.
<i>e</i>	(local) Pointer to the local part of the global vector <i>du</i> storing the upper diagonal of the matrix; must be of size $\geq nb\_a$. Globally, <i>du</i> (<i>n</i>) is not referenced, and <i>du</i> must be aligned with <i>d</i> .
<i>ja</i>	(global) The index in the global matrix <i>A</i> that points to the start of the matrix to be operated on (which may be either all of <i>A</i> or a submatrix of <i>A</i>).
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> . If 1D type (<i>dtype_a</i> = 501 or 502), then <i>dlen</i> ≥ 7 ; If 2D type (<i>dtype_a</i> = 1), then <i>dlen</i> ≥ 9 . Contains information on mapping of <i>A</i> to memory. See ScaLAPACK manual for full description and options.
<i>b</i>	(local) Pointer into the local memory to an array of local lead size $lld\_b \geq nb$. On entry, this array contains the local pieces of the right hand sides $B(jb:jb+n-1, 1:nrhs)$.

<i>ib</i>	(global) The row index in the global matrix <i>B</i> that points to the first row of the matrix to be operated on (which may be either all of <i>B</i> or a submatrix of <i>B</i>).
<i>descb</i>	(global and local) array of size <i>dlen_</i>. The array descriptor for the distributed matrix <i>B</i>. If 1D type (<i>dtype_b</i> = 502), then <i>dlen</i> ≥ 7; If 2D type (<i>dtype_b</i> = 1), then <i>dlen</i> ≥ 9. Contains information on mapping of <i>B</i> to memory. See ScaLAPACK manual for full description and options.
<i>laf</i>	(local) The size of user-input auxiliary fill-in space <i>af</i>. Must be $laf \geq (nb + 2 * bw) * bw$. If <i>laf</i> is not large enough, an error code will be returned and the minimum acceptable size will be returned in <i>af</i>[0].
<i>work</i>	(local) The array <i>work</i> is a temporary workspace array of size <i>lwork</i>. This space may be overwritten in between function calls.
<i>lwork</i>	(local or global) The size of the user-input workspace <i>work</i> , must be at least $lwork \geq (10 + 2 * \min(100, nrhs)) * npcol + 4 * nrhs$. If <i>lwork</i> is too small, the minimal acceptable size will be returned in <i>work</i> [0] and an error code is returned.

Output Parameters

<i>d, e</i>	(local). On exit, these arrays contain information on the factors of the matrix.
<i>af</i>	(local) The array <i>af</i> is of size <i>laf</i>. It contains auxiliary fill-in space. The fill-in space is created in a call to the factorization function p?pbtrf and is stored in <i>af</i>. If a linear system is to be solved using p?pttrs after the factorization function, <i>af</i> must not be altered after the factorization.
<i>b</i>	On exit, this array contains the local piece of the solutions distributed matrix <i>X</i> .
<i>work</i> [0]	On exit, <i>work</i> [0] contains the minimum value of <i>lwork</i> .
<i>info</i>	(local) = 0: successful exit < 0: if the <i>i</i>-th argument is an array and the <i>j</i>-th entry, indexed <i>j</i>-1, had an illegal value, then $info = -(i * 100 + j)$, if the <i>i</i>-th argument is a scalar and had an illegal value, then $info = -i$.

p?potf2

Computes the Cholesky factorization of a symmetric/Hermitian positive definite matrix (local unblocked algorithm).

Syntax

```
void pspotf2 (char *uplo , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , MKL_INT *info );

void pdpotf2 (char *uplo , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_INT *info );

void pcpotf2 (char *uplo , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_INT *info );

void pzpotf2 (char *uplo , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The p?potf2 function computes the Cholesky factorization of a real symmetric or complex Hermitian positive definite distributed matrix sub (A)=A(ia:ia+n-1, ja:ja+n-1).

The factorization has the form

$\text{sub}(A) = U^*U$, if $\text{uplo} = 'U'$, or $\text{sub}(A) = L^*L'$, if $\text{uplo} = 'L'$,

where U is an upper triangular matrix, L is lower triangular. X' denotes transpose (conjugate transpose) of X .

Input Parameters

<i>uplo</i>	(global) Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix A is stored. = 'U': upper triangle of sub (A) is stored; = 'L': lower triangle of sub (A) is stored.
<i>n</i>	(global) The number of rows and columns to be operated on, that is, the order of the distributed matrix sub (A). $n \geq 0$.
<i>a</i>	(local) Pointer into the local memory to an array of size $\text{lld}_a * \text{LOCc}(ja+n-1)$ containing the local pieces of the n -by- n symmetric distributed matrix sub(A) to be factored. If $\text{uplo} = 'U'$, the leading n -by- n upper triangular part of sub(A) contains the upper triangular matrix and the strictly lower triangular part of this matrix is not referenced.

If `uplo = 'L'`, the leading n -by- n lower triangular part of `sub(A)` contains the lower triangular matrix and the strictly upper triangular part of `sub(A)` is not referenced.

`ia, ja`

(global)

The row and column indices in the global matrix A indicating the first row and the first column of the `sub(A)`, respectively.

`desca`

(global and local) array of size `dlen_`. The array descriptor for the distributed matrix A .

Output Parameters

`a`

(local)

On exit,

if `uplo = 'U'`, the upper triangular part of the distributed matrix contains the Cholesky factor U ;

if `uplo = 'L'`, the lower triangular part of the distributed matrix contains the Cholesky factor L .

`info`

(local)

= 0: successful exit

< 0: if the i -th argument is an array and the j -th entry, indexed $j-1$, had an illegal value,

then `info = - (i*100 + j)`,

if the i -th argument is a scalar and had an illegal value,

then `info = -i`.

> 0: if `info = k`, the leading minor of order k is not positive definite, and the factorization could not be completed.

p?rot

Applies a planar rotation to two distributed vectors.

Syntax

```
void psrot(MKL_INT* n, float* x, MKL_INT* ix, MKL_INT* jx, MKL_INT* descx, MKL_INT*
incx, float* y, MKL_INT* iy, MKL_INT* jy, MKL_INT* descy, MKL_INT* incy, float* cs,
float* sn, float* work, MKL_INT* lwork, MKL_INT* info);
```

```
void pdrot(MKL_INT* n, double* x, MKL_INT* ix, MKL_INT* jx, MKL_INT* descx, MKL_INT*
incx, double* y, MKL_INT* iy, MKL_INT* jy, MKL_INT* descy, MKL_INT* incy, double* cs,
double* sn, double* work, MKL_INT* lwork, MKL_INT* info);
```

Include Files

- `mk1_scalapack.h`

Description

`zrot` applies a planar rotation defined by cs and sn to the two distributed vectors `sub(x)` and `sub(y)`.

Input Parameters

n	(global) The number of elements to operate on when applying the planar rotation to x and y ($n \geq 0$).
x	(local) array of size $((j_x-1)*m_x + ix + (n-1)*abs(incx))$ This array contains the entries of the distributed vector <code>sub(x)</code> .
ix	(global) The global row index of the submatrix of the distributed matrix x to operate on. If $incx = 1$, then it is required that $ix = iy$. $1 \leq ix \leq m_x$.
jx	(global) The global column index of the submatrix of the distributed matrix x to operate on. If $incx = m_x$, then it is required that $jx = jy$. $1 \leq jx \leq n_x$.
$descx$	(global and local) array of size 9 The array descriptor of the distributed matrix x .
$incx$	(global) The global increment for the elements of x . Only two values of $incx$ are supported in this version, namely 1 and m_x . Moreover, it must hold that $incx = m_x$ if $incy = m_y$ and that $incx = 1$ if $incy = 1$.
y	(local) array of size $((j_y-1)*m_y + iy + (n-1)*abs(incy))$ This array contains the entries of the distributed vector <code>sub(y)</code> .
iy	(global) The global row index of the submatrix of the distributed matrix y to operate on. If $incy = 1$, then it is required that $iy = ix$. $1 \leq iy \leq m_y$.
jy	(global) The global column index of the submatrix of the distributed matrix y to operate on. If $incy = m_x$, then it is required that $jy = jx$. $1 \leq jy \leq m_y$.
$descy$	(global and local) array of size 9 The array descriptor of the distributed matrix y .
$incy$	(global) The global increment for the elements of y . Only two values of $incy$ are supported in this version, namely 1 and m_y . Moreover, it must hold that $incy = m_y$ if $incx = m_x$ and that $incy = 1$ if $incx = 1$.
cs, sn	(global)

The parameters defining the properties of the planar rotation. It must hold that $0 \leq cs, sn \leq 1$ and that $sn^2 + cs^2 = 1$. The latter is hardly checked in finite precision arithmetics.

work (local workspace) array of size *lwork*

lwork (local)

The length of the workspace array *work*.

If *incx* = 1 and *incy* = 1, then *lwork* = 2*m_x

If *lwork* = -1, then a workspace query is assumed; the function only calculates the optimal size of the *work* array, returns this value as the first entry of the IWORK array, and no error message related to LIWORK is issued by [pxerbla](#).

OUTPUT Parameters

x

y

work[0] On exit, if *info* = 0, *work*[0] returns the optimal *lwork*

info

(global)

= 0: successful exit

< 0: if *info* = -*i*, the *i*-th argument had an illegal value.

If the *i*-th argument is an array and the *j*-th entry, indexed *j*-1, had an illegal value, then *info* = -(*i**100+*j*), if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

p?rscl

Multiplies a vector by the reciprocal of a real scalar.

Syntax

```
void psrscl (MKL_INT *n , float *sa , float *sx , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx );
```

```
void pdrscl (MKL_INT *n , double *sa , double *sx , MKL_INT *ix , MKL_INT *jx ,
MKL_INT *descx , MKL_INT *incx );
```

```
void pcsrscl (MKL_INT *n , float *sa , MKL_Complex8 *sx , MKL_INT *ix , MKL_INT *jx ,
MKL_INT *descx , MKL_INT *incx );
```

```
void pzdrscl (MKL_INT *n , double *sa , MKL_Complex16 *sx , MKL_INT *ix , MKL_INT *jx ,
MKL_INT *descx , MKL_INT *incx );
```

Include Files

- `mkl_scalapack.h`

Description

The `p?rscl` function multiplies an n -element real/complex vector `sub(X)` by the real scalar $1/a$. This is done without overflow or underflow as long as the final result `sub(X)/a` does not overflow or underflow.

`sub(X)` denotes $X(ix:ix+n-1, jx:jx)$, if $incx = 1$,

and $X(ix:ix, jx:jx+n-1)$, if $incx = m\_x$.

Input Parameters

n	(global) The number of components of the distributed vector <code>sub(X)</code> . $n \geq 0$.
sa	The scalar a that is used to divide each component of the vector <code>sub(X)</code> . This parameter must be ≥ 0 .
sx	Array containing the local pieces of a distributed matrix of size of at least $((jx-1)*m\_x + ix + (n-1)*abs(incx))$. This array contains the entries of the distributed vector <code>sub(X)</code> .
ix	(global) The row index of the submatrix of the distributed matrix X to operate on.
jx	(global) The column index of the submatrix of the distributed matrix X to operate on.
$descx$	(global and local) Array of size 9. The array descriptor for the distributed matrix X .
$incx$	(global) The increment for the elements of X . This version supports only two values of $incx$, namely 1 and m_x .

Output Parameters

sx	On exit, the result x/a .

p?sygs2/p?hegs2

Reduces a symmetric/Hermitian positive-definite generalized eigenproblem to standard form, using the factorization results obtained from `p?potrf` (local unblocked algorithm).

Syntax

```
void pssygs2 (MKL_INT *ibtype , char *uplo , MKL_INT *n , float *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , float *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb ,
MKL_INT *info );
```

```

void pdsygs2 (MKL_INT *ibtype , char *uplo , MKL_INT *n , double *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , double *b , MKL_INT *ib , MKL_INT *jb , MKL_INT
*descb , MKL_INT *info );

void pchehs2 (MKL_INT *ibtype , char *uplo , MKL_INT *n , MKL_Complex8 *a , MKL_INT
*ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex8 *b , MKL_INT *ib , MKL_INT *jb ,
MKL_INT *descb , MKL_INT *info );

void pzhehs2 (MKL_INT *ibtype , char *uplo , MKL_INT *n , MKL_Complex16 *a , MKL_INT
*ia , MKL_INT *ja , MKL_INT *desca , MKL_Complex16 *b , MKL_INT *ib , MKL_INT *jb ,
MKL_INT *descb , MKL_INT *info );

```

Include Files

- mkl_scalapack.h

Description

The `p?sygs2`/`p?hehs2` function reduces a real symmetric-definite or a complex Hermitian positive-definite generalized eigenproblem to standard form.

Here $\text{sub}(A)$ denotes $A(ia:ia+n-1, ja:ja+n-1)$, and $\text{sub}(B)$ denotes $B(ib:ib+n-1, jb:jb+n-1)$.

If $ibtype = 1$, the problem is

$$\text{sub}(A) * x = \lambda * \text{sub}(B) * x$$

and $\text{sub}(A)$ is overwritten by

$\text{inv}(U^T) * \text{sub}(A) * \text{inv}(U)$ or $\text{inv}(L) * \text{sub}(A) * \text{inv}(L^T)$ - for real flavors, and

$\text{inv}(U^H) * \text{sub}(A) * \text{inv}(U)$ or $\text{inv}(L) * \text{sub}(A) * \text{inv}(L^H)$ - for complex flavors.

If $ibtype = 2$ or 3 , the problem is

$$\text{sub}(A) * \text{sub}(B) x = \lambda * x \text{ or } \text{sub}(B) * \text{sub}(A) x = \lambda * x$$

and $\text{sub}(A)$ is overwritten by

$U * \text{sub}(A) * U^T$ or $L * T * \text{sub}(A) * L^T$ for real flavors and

$U * \text{sub}(A) * U^H$ or $L * H * \text{sub}(A) * L^H$ for complex flavors.

The matrix $\text{sub}(B)$ must have been previously factorized as $U^T * U$ or $L * L^T$ (for real flavors), or as $U^H * U$ or $L * L^H$ (for complex flavors) by [p?potrf](#).

Input Parameters

<i>ibtype</i>	(global)
= 1:	
	compute $\text{inv}(U^T) * \text{sub}(A) * \text{inv}(U)$, or $\text{inv}(L) * \text{sub}(A) * \text{inv}(L^T)$ for real functions,
	and $\text{inv}(U^H) * \text{sub}(A) * \text{inv}(U)$, or $\text{inv}(L) * \text{sub}(A) * \text{inv}(L^H)$ for complex functions;
= 2 or 3:	
	compute $U * \text{sub}(A) * U^T$, or $L * T * \text{sub}(A) * L^T$ for real functions,
	and $U * \text{sub}(A) * U^H$ or $L * H * \text{sub}(A) * L^H$ for complex functions.
<i>uplo</i>	(global)

Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix $\text{sub}(A)$ is stored, and how $\text{sub}(B)$ is factorized.

= 'U': Upper triangular of $\text{sub}(A)$ is stored and $\text{sub}(B)$ is factorized as $U^T * U$ (for real functions) or as $U^H * U$ (for complex functions).

= 'L': Lower triangular of $\text{sub}(A)$ is stored and $\text{sub}(B)$ is factorized as $L * L^T$ (for real functions) or as $L * L^H$ (for complex functions)

n (global)

The order of the matrices $\text{sub}(A)$ and $\text{sub}(B)$. $n \geq 0$.

a (local)

Pointer into the local memory to an array of size $lld\_a * LOCc(ja+n-1)$.

On entry, this array contains the local pieces of the n -by- n symmetric/Hermitian distributed matrix $\text{sub}(A)$.

If $uplo = 'U'$, the leading n -by- n upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and the strictly lower triangular part of $\text{sub}(A)$ is not referenced.

If $uplo = 'L'$, the leading n -by- n lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the matrix, and the strictly upper triangular part of $\text{sub}(A)$ is not referenced.

ia, ja (global)

The row and column indices in the global matrix A indicating the first row and the first column of the $\text{sub}(A)$, respectively.

desca (global and local) array of size $dlen\_$. The array descriptor for the distributed matrix A .

B (local)

Pointer into the local memory to an array of size $lld\_b * LOCc(jb+n-1)$.

On entry, this array contains the local pieces of the triangular factor from the Cholesky factorization of $\text{sub}(B)$ as returned by [p?potrf](#).

ib, jb (global)

The row and column indices in the global matrix B indicating the first row and the first column of the $\text{sub}(B)$, respectively.

descb (global and local) array of size $dlen\_$. The array descriptor for the distributed matrix B .

Output Parameters

a (local)

On exit, if $info = 0$, the transformed matrix is stored in the same format as $\text{sub}(A)$.

info

= 0: successful exit.

< 0: if the i -th argument is an array and the j -th entry, indexed $j-1$, had an illegal value,

then $info = -(i*100 + j)$,
 if the i -th argument is a scalar and had an illegal value,
 then $info = -i$.

See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

p?sytd2/p?hetd2

Reduces a symmetric/Hermitian matrix to real symmetric tridiagonal form by an orthogonal/unitary similarity transformation (local unblocked algorithm).

Syntax

```
void pssytd2 (char *uplo, MKL_INT *n, float *a, MKL_INT *ia, MKL_INT *ja, MKL_INT
*desca, float *d, float *e, float *tau, float *work, MKL_INT *lwork, MKL_INT *info);

void pdsytd2 (char *uplo, MKL_INT *n, double *a, MKL_INT *ia, MKL_INT *ja, MKL_INT
*desca, double *d, double *e, double *tau, double *work, MKL_INT *lwork, MKL_INT
*info);

void pchetd2 (char *uplo, MKL_INT *n, MKL_Complex8 *a, MKL_INT *ia, MKL_INT *ja,
MKL_INT *desca, float *d, float *e, MKL_Complex8 *tau, MKL_Complex8 *work, MKL_INT
*lwork, MKL_INT *info);

void pzhetd2 (char *uplo, MKL_INT *n, MKL_Complex16 *a, MKL_INT *ia, MKL_INT *ja,
MKL_INT *desca, double *d, double *e, MKL_Complex16 *tau, MKL_Complex16 *work, MKL_INT
*lwork, MKL_INT *info);
```

Include Files

- mkl_scalapack.h

Description

The p?sytd2/p?hetd2 function reduces a real symmetric/complex Hermitian matrix $\text{sub}(A)$ to symmetric/Hermitian tridiagonal form T by an orthogonal/unitary similarity transformation:

$Q' * \text{sub}(A) * Q = T$, where $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$.

Input Parameters

$uplo$	(global) Specifies whether the upper or lower triangular part of the symmetric/Hermitian matrix $\text{sub}(A)$ is stored: = 'U': upper triangular = 'L': lower triangular
n	(global) The number of rows and columns to be operated on, that is, the order of the distributed matrix $\text{sub}(A)$. $n \geq 0$.
a	(local) Pointer into the local memory to an array of size $lld\_a * LOC_c(ja+n-1)$.

On entry, this array contains the local pieces of the n -by- n symmetric/Hermitian distributed matrix $\text{sub}(A)$.

If $\text{uplo} = 'U'$, the leading n -by- n upper triangular part of $\text{sub}(A)$ contains the upper triangular part of the matrix, and the strictly lower triangular part of $\text{sub}(A)$ is not referenced.

If $\text{uplo} = 'L'$, the leading n -by- n lower triangular part of $\text{sub}(A)$ contains the lower triangular part of the matrix, and the strictly upper triangular part of $\text{sub}(A)$ is not referenced.

ia, ja

(global)

The row and column indices in the global matrix A indicating the first row and the first column of the $\text{sub}(A)$, respectively.

desca

(global and local) array of size $dlen\_$. The array descriptor for the distributed matrix A .

work

(local)

The array *work* is a temporary workspace array of size $lwork$.

Output Parameters

a

On exit, if $\text{uplo} = 'U'$, the diagonal and first superdiagonal of $\text{sub}(A)$ are overwritten by the corresponding elements of the tridiagonal matrix T , and the elements above the first superdiagonal, with the array *tau*, represent the orthogonal/unitary matrix Q as a product of elementary reflectors;

if $\text{uplo} = 'L'$, the diagonal and first subdiagonal of A are overwritten by the corresponding elements of the tridiagonal matrix T , and the elements below the first subdiagonal, with the array *tau*, represent the orthogonal/unitary matrix Q as a product of elementary reflectors. See the *Application Notes* below.

d

(local)

Array of size $LOCc(ja+n-1)$. The diagonal elements of the tridiagonal matrix T :

$d[i] = A(i+1, i+1)$, where $i=0, 1, \dots, LOCc(ja+n-1) - 1$; d is tied to the distributed matrix A .

e

(local)

Array of size $LOCc(ja+n-1)$,

if $\text{uplo} = 'U'$, $LOCc(ja+n-2)$ otherwise.

The off-diagonal elements of the tridiagonal matrix T :

$e[i] = A(i+1, i+2)$ if $\text{uplo} = 'U'$,

$e[i] = A(i+2, i+1)$ if $\text{uplo} = 'L'$,

where $i=0, 1, \dots, LOCc(ja+n-1) - 1$.

e is tied to the distributed matrix A .

tau

(local)

Array of size $LOCc(ja+n-1)$.

	The scalar factors of the elementary reflectors. <i>tau</i> is tied to the distributed matrix <i>A</i> .
<i>work</i> [0]	On exit, <i>work</i> [0] returns the minimal and optimal value of <i>lwork</i> .
<i>lwork</i>	(local or global) The size of the workspace array <i>work</i> . <i>lwork</i> is local input and must be at least $lwork \geq 3n$. If <i>lwork</i> = -1, then <i>lwork</i> is global input and a workspace query is assumed; the function only calculates the minimum and optimal size for all work arrays. Each of these values is returned in the first entry of the corresponding work array, and no error message is issued by pxerbla .
<i>info</i>	(local) = 0: successful exit < 0: if the <i>i</i> -th argument, indexed <i>i</i> -1, is an array and the <i>j</i> -th entry had an illegal value, then <i>info</i> = -(<i>i</i> *100+ <i>j</i>), if the <i>i</i> -th argument is a scalar and had an illegal value, then <i>info</i> = - <i>i</i> .

Application Notes

If *uplo* = 'U', the matrix *Q* is represented as a product of elementary reflectors

$$Q = H(n-1) * \dots * H(2) * H(1)$$

Each *H*(*i*) has the form

$$H(i) = I - \tau v v',$$

where *tau* is a real/complex scalar, and *v* is a real/complex vector with $v(i+1:n) = 0$ and $v(i) = 1$; $v(1:i-1)$ is stored on exit in $A(ia:ia+i-2, ja+i)$, and *tau* in $\tau[ja+i-2]$.

If *uplo* = 'L', the matrix *Q* is represented as a product of elementary reflectors

$$Q = H(1) * H(2) * \dots * H(n-1).$$

Each *H*(*i*) has the form

$$H(i) = I - \tau v v',$$

where *tau* is a real/complex scalar, and *v* is a real/complex vector with $v(1:i) = 0$ and $v(i+1) = 1$; $v(i+2:n)$ is stored on exit in $A(ia+i+1:ia+n-1, ja+i-1)$, and *tau* in $\tau[ja+i-2]$.

The contents of sub (A) on exit are illustrated by the following examples with $n = 5$:

$$\begin{array}{l} \text{if } \text{uplo}=\text{'U'}: \\ \begin{bmatrix} d & e & v_2 & v_3 & v_4 \\ & d & e & v_3 & v_4 \\ & & d & e & v_4 \\ & & & d & e \\ & & & & d \end{bmatrix} \\ \\ \text{if } \text{uplo}=\text{'L'}: \\ \begin{bmatrix} d & & & & \\ e & d & & & \\ v_1 & e & d & & \\ v_1 & v_2 & e & d & \\ v_1 & v_2 & v_3 & e & d \end{bmatrix} \end{array}$$

where d and e denotes diagonal and off-diagonal elements of T , and v_i denotes an element of the vector defining $H(i)$.

NOTE

The distributed matrix sub(A) must verify some alignment properties, namely the following expression should be true:

```
( mb_a==nb_a && iroffa==icoffa ) where iroffa = mod(ia - 1, mb_a) and icoffa = mod(ja - 1, nb_a).
```

p?trord

Reorders the Schur factorization of a general matrix.

Syntax

```
void pstrord( char* compq, MKL_INT* select, MKL_INT* para, MKL_INT* n, float* t,
MKL_INT* it, MKL_INT* jt, MKL_INT* desct, float* q, MKL_INT* iq, MKL_INT* jq, MKL_INT*
descq, float* wr, float* wi, MKL_INT* m, float* work, MKL_INT* lwork, MKL_INT* iwork,
MKL_INT* liwork, MKL_INT* info);
```

```
void pdtrord(char* compq, MKL_INT* select, MKL_INT* para, MKL_INT* n, double* t,
MKL_INT* it, MKL_INT* jt, MKL_INT* desct, double* q, MKL_INT* iq, MKL_INT* jq,
MKL_INT* descq, double* wr, double* wi, MKL_INT* m, double* work, MKL_INT* lwork,
MKL_INT* iwork, MKL_INT* liwork, MKL_INT* info);
```

Include Files

- mkl_scalapack.h

Description

`p?trord` reorders the real Schur factorization of a real matrix $A = Q^*T^*Q^T$, so that a selected cluster of eigenvalues appears in the leading diagonal blocks of the upper quasi-triangular matrix T , and the leading columns of Q form an orthonormal basis of the corresponding right invariant subspace.

T must be in Schur form (as returned by `p?lahqr`), that is, block upper triangular with 1-by-1 and 2-by-2 diagonal blocks.

This function uses a delay and accumulate procedure for performing the off-diagonal updates.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

<i>compq</i>	(global) = 'V': update the matrix <i>q</i> of Schur vectors; = 'N': do not update <i>q</i> .
<i>select</i>	(global) array of size <i>n</i> <i>select</i> specifies the eigenvalues in the selected cluster. To select a real eigenvalue $w(j)$, <i>select</i> [<i>j</i> -1] must be set to 1. To select a complex conjugate pair of eigenvalues $w(j)$ and $w(j+1)$, corresponding to a 2-by-2 diagonal block, either <i>select</i> [<i>j</i> -1] or <i>select</i> [<i>j</i>] or both must be set to 1; a complex conjugate pair of eigenvalues must be either both included in the cluster or both excluded.
<i>para</i>	(global) Block parameters:
<i>para</i> [0]	maximum number of concurrent computational windows allowed in the algorithm; $0 < para[0] \leq \min(nprow, npcol)$ must hold;
<i>para</i> [1]	number of eigenvalues in each window; $0 < para[1] < para[2]$ must hold;
<i>para</i> [2]	window size; $para[1] < para[2] < mb\_t$ must hold;
<i>para</i> [3]	minimal percentage of FLOPS required for performing matrix-matrix multiplications instead of pipelined orthogonal transformations; $0 \leq para[3] \leq 100$ must hold;
<i>para</i> [4]	width of block column slabs for row-wise application of pipelined orthogonal transformations in their factorized form; $0 < para[4] \leq mb\_t$ must hold.
<i>para</i> [5]	the maximum number of eigenvalues moved together over a process border; in practice, this will be approximately half of the cross border window size; $0 < para[5] \leq para[1]$ must hold.

n	(global) The order of the globally distributed matrix t . $n \geq 0$.
t	(local) array of size $lld\_t * LOC_c(n)$. The local pieces of the global distributed upper quasi-triangular matrix T , in Schur form.
it, jt	(global) The row and column index in the global matrix T indicating the first column of T . $it = jt = 1$ must hold (see Application Notes).
$desct$	(global and local) array of size $dlen\_$. The array descriptor for the global distributed matrix T .
q	(local) array of size $lld\_q * LOC_c(n)$. On entry, if $compq = 'V'$, the local pieces of the global distributed matrix Q of Schur vectors. If $compq = 'N'$, q is not referenced.
iq, jq	(global) The column index in the global matrix Q indicating the first column of Q . $iq = jq = 1$ must hold (see Application Notes).
$descq$	(global and local) array of size $dlen\_$. The array descriptor for the global distributed matrix Q .
$work$	(local workspace) array of size $lwork$
$lwork$	(local) The size of the array $work$. If $lwork = -1$, then a workspace query is assumed; the function only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued by pxerbla .
$iwork$	(local workspace) array of size $liwork$
$liwork$	(local) The size of the array $iwork$. If $liwork = -1$, then a workspace query is assumed; the function only calculates the optimal size of the $iwork$ array, returns this value as the first entry of the $iwork$ array, and no error message related to $liwork$ is issued by pxerbla .

OUTPUT Parameters

$select$	(global) array of size n The (partial) reordering is displayed.

t	On exit, t is overwritten by the local pieces of the reordered matrix T , again in Schur form, with the selected eigenvalues in the globally leading diagonal blocks.
q	On exit, if $compq = 'V'$, q has been postmultiplied by the global orthogonal transformation matrix which reorders t ; the leading m columns of q form an orthonormal basis for the specified invariant subspace. If $compq = 'N'$, q is not referenced.
wr, wi	(global) array of size n The real and imaginary parts, respectively, of the reordered eigenvalues of the matrix T . The eigenvalues are in principle stored in the same order as on the diagonal of T , with $wr[i] = T(i+1,i+1)$ and, if $T(i:i+1,i:i+1)$ is a 2-by-2 diagonal block, $wi[i-1] > 0$ and $wi[i] = -wi[i-1]$. Note also that if a complex eigenvalue is sufficiently ill-conditioned, then its value may differ significantly from its value before reordering.
m	(global) The size of the specified invariant subspace. $0 \leq m \leq n$.
$work[0]$	On exit, if $info = 0$, $work[0]$ returns the optimal $lwork$.
$iwork[0]$	On exit, if $info = 0$, $iwork[0]$ returns the optimal $liwork$.
$info$	(global) = 0: successful exit < 0: if $info = -i$, the i -th argument had an illegal value. If the i -th argument is an array and the j -th entry, indexed $j-1$, had an illegal value, then $info = -(i*1000+j)$, if the i -th argument is a scalar and had an illegal value, then $info = -i$. > 0: here we have several possibilities • Reordering of t failed because some eigenvalues are too close to separate (the problem is very ill-conditioned); t may have been partially reordered, and wr and wi contain the eigenvalues in the same order as in t. On exit, $info = \{\text{the index of } t \text{ where the swap failed (indexing starts at 1)}\}$. • A 2-by-2 block to be reordered split into two 1-by-1 blocks and the second block failed to swap with an adjacent block. On exit, $info = \{\text{the index of } t \text{ where the swap failed}\}$. • If $info = n+1$, there is no valid BLACS context (see the BLACS documentation for details).

Application Notes

The following alignment requirements must hold:

- $mb\_t = nb\_t = mb\_q = nb\_q$

- $rsrc\_t = rsrc\_q$
- $csrc\_t = csrc\_q$

All matrices must be blocked by a block factor larger than or equal to two (3). This is to simplify reordering across processor borders in the presence of 2-by-2 blocks.

This algorithm cannot work on submatrices of t and q , i.e., $it = jt = iq = jq = 1$ must hold. This is however no limitation since [p?lahqr](#) does not compute Schur forms of submatrices anyway.

Parallel execution recommendations:

- Use a square grid, if possible, for maximum performance. The block parameters in *para* should be kept well below the data distribution block size.
- In general, the parallel algorithm strives to perform as much work as possible without crossing the block borders on the main block diagonal.

See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

p?trsen

Reorders the Schur factorization of a matrix and (optionally) computes the reciprocal condition numbers and invariant subspace for the selected cluster of eigenvalues.

Syntax

```
void pstrsen(char* job, char* compq, MKL_INT* select, MKL_INT* para, MKL_INT* n,
float* t, MKL_INT* it, MKL_INT* jt, MKL_INT* descq, float* q, MKL_INT* iq, MKL_INT*
jq, MKL_INT* descq, float* wr, float* wi, MKL_INT* m, float* s, float* sep, float*
work, MKL_INT* lwork, MKL_INT* iwork, MKL_INT* liwork, MKL_INT* info);
```

Notice revision #20110804

Input Parameters

<i>job</i>	(global) Specifies whether condition numbers are required for the cluster of eigenvalues (<i>s</i>) or the invariant subspace (<i>sep</i>): = 'N': no condition numbers are required; = 'E': only the condition number for the cluster of eigenvalues is computed (<i>s</i>); = 'V': only the condition number for the invariant subspace is computed (<i>sep</i>); = 'B': condition numbers for both the cluster and the invariant subspace are computed (<i>s</i> and <i>sep</i>).						
<i>compq</i>	(global) = 'V': update the matrix <i>q</i> of Schur vectors; = 'N': do not update <i>q</i> .						
<i>select</i>	(global) array of size <i>n</i> <i>select</i> specifies the eigenvalues in the selected cluster. To select a real eigenvalue $w(j)$, <i>select</i> [<i>j</i> -1] must be set to a non-zero number. To select a complex conjugate pair of eigenvalues $w(j)$ and $w(j+1)$, corresponding to a 2-by-2 diagonal block, either <i>select</i> [<i>j</i> -1] or <i>select</i> [<i>j</i>] or both must be set to a non-zero number; a complex conjugate pair of eigenvalues must be either both included in the cluster or both excluded.						
<i>para</i>	(global) Block parameters: <table> <tr> <td><i>para</i>[0]</td><td>maximum number of concurrent computational windows allowed in the algorithm; $0 < para[0] \leq \min(NPROW, NPCOL)$ must hold;</td></tr> <tr> <td><i>para</i>[1]</td><td>number of eigenvalues in each window; $0 < para[1] < para[2]$ must hold;</td></tr> <tr> <td><i>para</i>[2]</td><td>window size; $para[1] < para[2] < mb\_t$ must hold;</td></tr> </table>	<i>para</i> [0]	maximum number of concurrent computational windows allowed in the algorithm; $0 < para[0] \leq \min(NPROW, NPCOL)$ must hold;	<i>para</i> [1]	number of eigenvalues in each window; $0 < para[1] < para[2]$ must hold;	<i>para</i> [2]	window size; $para[1] < para[2] < mb\_t$ must hold;
<i>para</i> [0]	maximum number of concurrent computational windows allowed in the algorithm; $0 < para[0] \leq \min(NPROW, NPCOL)$ must hold;						
<i>para</i> [1]	number of eigenvalues in each window; $0 < para[1] < para[2]$ must hold;						
<i>para</i> [2]	window size; $para[1] < para[2] < mb\_t$ must hold;						

	<i>para</i> [3]	minimal percentage of flops required for performing matrix-matrix multiplications instead of pipelined orthogonal transformations; $0 \leq para[3] \leq 100$ must hold;
	<i>para</i> [4]	width of block column slabs for row-wise application of pipelined orthogonal transformations in their factorized form; $0 < para[4] \leq mb\_t$ must hold.
	<i>para</i> [5]	the maximum number of eigenvalues moved together over a process border; in practice, this will be approximately half of the cross border window size $0 < para[5] \leq para[1]$ must hold;
<i>n</i>	(global) The order of the globally distributed matrix <i>t</i> . $n \geq 0$.	
<i>t</i>	(local) array of size $lld\_t * LOC_c(n)$. The local pieces of the global distributed upper quasi-triangular matrix <i>T</i> , in Schur form.	
<i>it, jt</i>	(global) The row and column index in the global matrix <i>T</i> indicating the first column of <i>T</i> . $it = jt = 1$ must hold (see Application Notes).	
<i>desct</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the global distributed matrix <i>T</i> .	
<i>q</i>	(local) array of size $lld\_q * LOC_c(n)$. On entry, if <i>compq</i> = 'V', the local pieces of the global distributed matrix <i>Q</i> of Schur vectors. If <i>compq</i> = 'N', <i>q</i> is not referenced.	
<i>iq, jq</i>	(global) The column index in the global matrix <i>Q</i> indicating the first column of <i>Q</i> . $iq = jq = 1$ must hold (see Application Notes).	
<i>descq</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the global distributed matrix <i>Q</i> .	
<i>work</i>	(local workspace) array of size <i>lwork</i>	
<i>lwork</i>	(local) The size of the array <i>work</i> . If <i>lwork</i> = -1, then a workspace query is assumed; the function only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued by pxerbla .	

iwork (local workspace) array of size *liwork*

liwork (local)
The size of the array *iwork*.
If *liwork* = -1, then a workspace query is assumed; the function only calculates the optimal size of the *iwork* array, returns this value as the first entry of the *iwork* array, and no error message related to *liwork* is issued by p_{xerbla}.

OUTPUT Parameters

t *t* is overwritten by the local pieces of the reordered matrix *T*, again in Schur form, with the selected eigenvalues in the globally leading diagonal blocks.

q On exit, if *compq* = 'V', *q* has been postmultiplied by the global orthogonal transformation matrix which reorders *t*; the leading *m* columns of *q* form an orthonormal basis for the specified invariant subspace.
If *compq* = 'N', *q* is not referenced.

wr, wi (global) array of size *n*
The real and imaginary parts, respectively, of the reordered eigenvalues of the matrix *T*. The eigenvalues are in principle stored in the same order as on the diagonal of *T*, with *wr*[*i*] = *T*(*i*+1,*i*+1) and, if *T*(*i*:*i*+1,*i*:*i*+1) is a 2-by-2 diagonal block, *wi*[*i*-1] > 0 and *wi*[*i*] = -*wi*[*i*-1].
Note also that if a complex eigenvalue is sufficiently ill-conditioned, then its value may differ significantly from its value before reordering.

m (global)
The size of the specified invariant subspace. $0 \leq m \leq n$.

s (global)
If *job* = 'E' or 'B', *s* is a lower bound on the reciprocal condition number for the selected cluster of eigenvalues. *s* cannot underestimate the true reciprocal condition number by more than a factor of sqrt(*n*). If *m* = 0 or *n*, *s* = 1.
If *job* = 'N' or 'V', *s* is not referenced.

sep (global)
If *job* = 'V' or 'B', *sep* is the estimated reciprocal condition number of the specified invariant subspace. If *m* = 0 or *n*, *sep* = norm(*t*).
If *job* = 'N' or 'E', *sep* is not referenced.

work[0] On exit, if *info* = 0, *work*[0] returns the optimal *lwork*.

iwork[0] On exit, if *info* = 0, *iwork*[0] returns the optimal *liwork*.

info (global)

= 0: successful exit

< 0: if *info* = -*i*, the *i*-th argument had an illegal value.

If the *i*-th argument is an array and the *j*-th entry, indexed *j*-1, had an illegal value, then *info* = -(*i**1000+*j*), if the *i*-th argument is a scalar and had an illegal value, then *info* = -*i*.

> 0: here we have several possibilities

- Reordering of *t* failed because some eigenvalues are too close to separate (the problem is very ill-conditioned); *t* may have been partially reordered, and *wr* and *wi* contain the eigenvalues in the same order as in *t*.

On exit, *info* = {the index of *t* where the swap failed (indexing starts at 1)}.

- A 2-by-2 block to be reordered split into two 1-by-1 blocks and the second block failed to swap with an adjacent block.

On exit, *info* = {the index of *t* where the swap failed}.

- If *info* = *n*+1, there is no valid BLACS context (see the BLACS documentation for details).

Application Notes

The following alignment requirements must hold:

- *mb_t* = *nb_t* = *mb_q* = *nb_q*
- *rsrc_t* = *rsrc_q*
- *csrc_t* = *csrc_q*

All matrices must be blocked by a block factor larger than or equal to two (3). This to simplify reordering across processor borders in the presence of 2-by-2 blocks.

This algorithm cannot work on submatrices of *t* and *q*, i.e., *it* = *jt* = *iq* = *jq* = 1 must hold. This is however no limitation since [p?lahqr](#) does not compute Schur forms of submatrices anyway.

For parallel execution, use a square grid, if possible, for maximum performance. The block parameters in *para* should be kept well below the data distribution block size.

In general, the parallel algorithm strives to perform as much work as possible without crossing the block borders on the main block diagonal.

p?trti2

Computes the inverse of a triangular matrix (local unblocked algorithm).

Syntax

```
void pstrti2 (char *uplo , char *diag , MKL_INT *n , float *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , MKL_INT *info );
```

```
void pdtrti2 (char *uplo , char *diag , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , MKL_INT *info );
```

```
void pctrti2 (char *uplo , char *diag , MKL_INT *n , MKL_Complex8 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
```

```
void pztrti2 (char *uplo , char *diag , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The `pztrti2` function computes the inverse of a real/complex upper or lower triangular block matrix $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$.

This matrix should be contained in one and only one process memory space (local operation).

Input Parameters

<i>uplo</i>	(global)	Specifies whether the matrix $\text{sub}(A)$ is upper or lower triangular. = 'U': $\text{sub}(A)$ is upper triangular = 'L': $\text{sub}(A)$ is lower triangular.
<i>diag</i>	(global)	Specifies whether or not the matrix A is unit triangular. = 'N': $\text{sub}(A)$ is non-unit triangular = 'U': $\text{sub}(A)$ is unit triangular.
<i>n</i>	(global)	The number of rows and columns to be operated on, i.e., the order of the distributed submatrix $\text{sub}(A)$. $n \geq 0$.
<i>a</i>	(local)	Pointer into the local memory to an array, size <code>lld_a * LOCc(ja+n-1)</code> . On entry, this array contains the local pieces of the triangular matrix $\text{sub}(A)$. If <i>uplo</i> = 'U', the leading n -by- n upper triangular part of the matrix $\text{sub}(A)$ contains the upper triangular part of the matrix, and the strictly lower triangular part of $\text{sub}(A)$ is not referenced. If <i>uplo</i> = 'L', the leading n -by- n lower triangular part of the matrix $\text{sub}(A)$ contains the lower triangular part of the matrix, and the strictly upper triangular part of $\text{sub}(A)$ is not referenced. If <i>diag</i> = 'U', the diagonal elements of $\text{sub}(A)$ are not referenced either and are assumed to be 1.
<i>ia, ja</i>	(global)	The row and column indices in the global matrix A indicating the first row and the first column of the $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local)	array of size <code>dlen_</code> . The array descriptor for the distributed matrix A .

Output Parameters

<i>a</i>	On exit, the (triangular) inverse of the original matrix, in the same storage format.
<i>info</i>	= 0: successful exit < 0: if the <i>i</i>-th argument is an array and the <i>j</i>-th entry, indexed <i>j</i>-1, had an illegal value, then <i>info</i> = - (<i>i</i>*100+<i>j</i>), if the <i>i</i>-th argument is a scalar and had an illegal value, then <i>info</i> = -<i>i</i>.

?lamsh

Sends multiple shifts through a small (single node) matrix to maximize the number of bulges that can be sent through.

Syntax

```
void slamsh (float *s , MKL_INT *lds , MKL_INT *nbulge , MKL_INT *jblk , float *h ,
MKL_INT *ldh , MKL_INT *n , float *ulp );
```

```
void dlamsh (double *s , MKL_INT *lds , MKL_INT *nbulge , MKL_INT *jblk , double *h ,
MKL_INT *ldh , MKL_INT *n , double *ulp );
```

Include Files

- mkl_scalapack.h

Description

The ?lamsh function sends multiple shifts through a small (single node) matrix to see how small consecutive subdiagonal elements are modified by subsequent shifts in an effort to maximize the number of bulges that can be sent through. The function should only be called when there are multiple shifts/bulges (*nbulge* > 1) and the first shift is starting in the middle of an unreduced Hessenberg matrix because of two or more small consecutive subdiagonal elements.

Input Parameters

<i>s</i>	(local) Array of size <i>lds</i>*2*<i>jblk</i>. On entry, the matrix of shifts. Only the 2x2 diagonal of <i>s</i> is referenced. It is assumed that <i>s</i> has <i>jblk</i> double shifts (size 2).
<i>lds</i>	(local) On entry, the leading dimension of <i>S</i>; unchanged on exit. $1 < nbulge \leq jblk \leq lds/2$.
<i>nbulge</i>	(local)

	On entry, the number of bulges to send through h (>1). $nbulge$ should be less than the maximum determined $(jblk) \cdot 1 < nbulge \leq jblk \leq lds/2$.
$jblk$	(local) On entry, the leading dimension of S ; unchanged on exit.
h	(local) Array of size lds by n . On entry, the local matrix to apply the shifts on. h should be aligned so that the starting row is 2.
ldh	(local) On entry, the leading dimension of H ; unchanged on exit.
n	(local) On entry, the size of H . If all the bulges are expected to go through, n should be at least $4nbulge+2$. Otherwise, $nbulge$ may be reduced by this function.
ulp	(local) On entry, machine precision. Unchanged on exit.

Output Parameters

s	On exit, the data is rearranged in the best order for applying.
$nbulge$	On exit, the maximum number of bulges that can be sent through.
h	On exit, the data is destroyed.

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

?laqr6

Performs a single small-bulge multi-shift QR sweep collecting the transformations.

Syntax

```
void slaqr6(char* job, MKL_INT* wantt, MKL_INT* wantz, MKL_INT* kacc22, MKL_INT* n,
MKL_INT* ktop, MKL_INT* kbot, MKL_INT* nshfts, float* sr, float* si, float* h,
MKL_INT* ldh, MKL_INT* iloz, MKL_INT* ihiz, float* z, MKL_INT* ldz, float* v, MKL_INT*
ldv, float* u, MKL_INT* ldu, MKL_INT* nv, float* wv, MKL_INT* ldwv, MKL_INT* nh,
float* wh, MKL_INT* ldwh);
```

```
void dlaqr6(char* job, MKL_INT* wantt, MKL_INT* wantz, MKL_INT* kacc22, MKL_INT* n,
MKL_INT* ktop, MKL_INT* kbot, MKL_INT* nshfts, double* sr, double* si, double* h,
MKL_INT* ldh, MKL_INT* iloz, MKL_INT* ihiz, double* z, MKL_INT* ldz, double* v,
MKL_INT* ldv, double* u, MKL_INT* ldu, MKL_INT* nv, double* wv, MKL_INT* ldwv,
MKL_INT* nh, double* wh, MKL_INT* ldwh);
```

Include Files

- `mkl_scalapack.h`

Description

This auxiliary function performs a single small-bulge multi-shift QR sweep, moving the chain of bulges from top to bottom in the submatrix $H(k_{top}:k_{bot}, k_{top}:k_{bot})$, collecting the transformations in the matrix V or accumulating the transformations in the matrix Z (see below).

This is a modified version of `?laqr5` from LAPACK 3.1.

Input Parameters

<i>job</i>	Set the kind of job to do in <code>?laqr6</code> , as follows: <code>job = 'I'</code> : Introduce and chase bulges in submatrix <code>job = 'C'</code> : Chase bulges from top to bottom of submatrix <code>job = 'O'</code> : Chase bulges off submatrix
<i>wantt</i>	<i>wantt</i> is non-zero if the quasi-triangular Schur factor is being computed. <i>wantt</i> is set to zero otherwise.
<i>wantz</i>	<i>wantz</i> is non-zero if the orthogonal Schur factor is being computed. <i>wantz</i> is set to zero otherwise.
<i>kacc22</i>	Specifies the computation mode of far-from-diagonal orthogonal updates. <code>= 0</code> : <code>?laqr6</code> does not accumulate reflections and does not use matrix-matrix multiply to update far-from-diagonal matrix entries. <code>= 1</code> : <code>?laqr6</code> accumulates reflections and uses matrix-matrix multiply to update the far-from-diagonal matrix entries. <code>= 2</code> : <code>?laqr6</code> accumulates reflections, uses matrix-matrix multiply to update the far-from-diagonal matrix entries, and takes advantage of 2-by-2 block structure during matrix multiplies.
<i>n</i>	<i>n</i> is the order of the Hessenberg matrix H upon which this function operates.
<i>ktop, kbot</i>	These are the first and last rows and columns of an isolated diagonal block upon which the QR sweep is to be applied. It is assumed without a check that either $k_{top} = 1$ or $H(k_{top}, k_{top}-1) = 0$ and either $k_{bot} = n$ or $H(k_{bot}+1, k_{bot}) = 0$.
<i>nshfts</i>	<i>nshfts</i> gives the number of simultaneous shifts. <i>nshfts</i> must be positive and even.
<i>sr, si</i>	Array of size <i>nshfts</i> <i>sr</i> contains the real parts and <i>si</i> contains the imaginary parts of the <i>nshfts</i> shifts of origin that define the multi-shift QR sweep.
<i>h</i>	Array of size $ldh * n$ On input <i>h</i> contains a Hessenberg matrix H .

<i>ldh</i>	<i>ldh</i> is the leading dimension of <i>H</i> just as declared in the calling function. $ldh \geq \max(1, n)$.
<i>iloz, ihiz</i>	Specify the rows of the matrix <i>Z</i> to which transformations must be applied if <i>wantzis</i> non-zero. $1 \leq iloz \leq ihiz \leq n$
<i>z</i>	Array of size $ldz * ktop$ If <i>wantzis</i> non-zero, then the QR sweep orthogonal similarity transformation is accumulated into the matrix <i>Z</i> (<i>iloz:ihiz</i> , <i>kbot:ktop</i>), stored in the array <i>z</i> , from the right. If <i>wantzequals</i> zero, then <i>z</i> is unreferenced.
<i>ldz</i>	<i>ldz</i> is the leading dimension of <i>z</i> just as declared in the calling function. $ldz \geq n$.
<i>v</i>	(workspace) array of size $ldv * nshfts/2$
<i>ldv</i>	<i>ldv</i> is the leading dimension of <i>v</i> as declared in the calling function. $ldv \geq 3$.
<i>u</i>	(workspace) array of size $ldu * (3*nshfts-3)$
<i>ldu</i>	<i>ldu</i> is the leading dimension of <i>u</i> just as declared in the calling function. $ldu \geq 3*nshfts-3$.
<i>nh</i>	<i>nh</i> is the number of columns in array <i>wh</i> available for workspace. $nh \geq 1$ is required for usage of this workspace, otherwise the updates of the far-from-diagonal elements will be updated without level 3 BLAS.
<i>wh</i>	(workspace) array of size $ldwh * nh$
<i>ldwh</i>	Leading dimension of <i>wh</i> just as declared in the calling function. $ldwh \geq 3*nshfts-3$.
<i>nv</i>	<i>nv</i> is the number of rows in <i>wv</i> available for workspace. $nv \geq 1$ is required for usage of this workspace, otherwise the updates of the far-from-diagonal elements will be updated without level 3 BLAS.
<i>wv</i>	(workspace) array of size $ldwv * 3*nshfts$
<i>ldwv</i>	scalar <i>ldwv</i> is the leading dimension of <i>wv</i> as declared in the in the calling function. $ldwv \geq nv$.

OUTPUT Parameters

<i>h</i>	A multi-shift QR sweep with shifts $sr[j] + i*si[j]$ is applied to the isolated diagonal block in matrix rows and columns <i>ktop</i> through <i>kbot</i> .
<i>z</i>	If <i>wantzis</i> non-zero, then the QR sweep orthogonal/unitary similarity transformation is accumulated into the matrix <i>Z</i> (<i>iloz:ihiz</i> , <i>kbot:ktop</i>) from the right. If <i>wantzequals</i> zero, then <i>z</i> is unreferenced.

Application Notes

?lar1va

Computes scaled eigenvector corresponding to given eigenvalue.

Syntax

```
void slarlva(MKL_INT* n, MKL_INT* b1, MKL_INT* bn, float* lambda, float* d, float* l,
float* ld, float* lld, float* pivmin, float* gaptol, float* z, MKL_INT* wantnc,
MKL_INT* negcnt, float* ztz, float* mingma, MKL_INT* r, MKL_INT* isuppz, float*
nrminv, float* resid, float* rqcorr, float* work);
```

```
void dlarlva(MKL_INT* n, MKL_INT* b1, MKL_INT* bn, double* lambda, double* d, double*
l, double* ld, double* lld, double* pivmin, double* gaptol, double* z, MKL_INT*
wantnc, MKL_INT* negcnt, double* ztz, double* mingma, MKL_INT* r, MKL_INT* isuppz,
double* nrminv, double* resid, double* rqcorr, double* work);
```

Include Files

- mkl_scalapack.h

Description

?slarlva computes the (scaled) r -th column of the inverse of the submatrix in rows $b1$ through bn of the tridiagonal matrix $LDL^T - \lambda I$. When λ is close to an eigenvalue, the computed vector is an accurate eigenvector. Usually, r corresponds to the index where the eigenvector is largest in magnitude. The following steps accomplish this computation :

1. Stationary qd transform, $LDL^T - \lambda I = L_+ D_+ L_+^T$,
2. Progressive qd transform, $LDL^T - \lambda I = U_- D_- U_-^T$,
3. Computation of the diagonal elements of the inverse of $LDL^T - \lambda I$ by combining the above transforms, and choosing r as the index where the diagonal of the inverse is (one of the) largest in magnitude.
4. Computation of the (scaled) r -th column of the inverse using the twisted factorization obtained by combining the top part of the stationary and the bottom part of the progressive transform.

Input Parameters

n	The order of the matrix LDL^T .
$b1$	First index of the submatrix of LDL^T .
bn	Last index of the submatrix of LDL^T .
$lambda$	The shift λ . In order to compute an accurate eigenvector, $lambda$ should be a good approximation to an eigenvalue of LDL^T .
l	Array of size $n-1$

	The $(n-1)$ subdiagonal elements of the unit bidiagonal matrix L , in elements 0 to $n-2$.
<i>d</i>	Array of size n The n diagonal elements of the diagonal matrix D .
<i>ld</i>	Array of size $n-1$ The $n-1$ elements $l[i]*d[i]$, $i=0,\dots,n-2$.
<i>lld</i>	Array of size $n-1$ The $n-1$ elements $l[i]*l[i]*d[i]$, $i=0,\dots,n-2$.
<i>pivmin</i>	The minimum pivot in the Sturm sequence.
<i>gaptol</i>	Tolerance that indicates when eigenvector entries are negligible with respect to their contribution to the residual.
<i>z</i>	Array of size n On input, all entries of z must be set to 0.
<i>wantnc</i>	Specifies whether <i>negcnt</i> has to be computed.
<i>r</i>	The twist index for the twisted factorization used to compute z . On input, $0 \leq r \leq n$. If r is input as 0, r is set to the index where $(LDL^T - \sigma I)^{-1}$ is largest in magnitude. If $1 \leq r \leq n$, r is unchanged. Ideally, r designates the position of the maximum entry in the eigenvector.
<i>work</i>	(Workspace) array of size $4*n$

OUTPUT Parameters

<i>z</i>	On output, z contains the (scaled) r -th column of the inverse. The scaling is such that $z[r-1]$ equals 1.
<i>negcnt</i>	If <i>wantnc</i> is non-zero then <i>negcnt</i> = the number of pivots $< pivmin$ in the matrix factorization LDL^T , and <i>negcnt</i> = -1 otherwise.
<i>ztz</i>	The square of the 2-norm of z .
<i>mingma</i>	The reciprocal of the largest (in magnitude) diagonal element of the inverse of $LDL^T - \sigma I$.
<i>r</i>	On output, r contains the twist index used to compute z .
<i>isuppz</i>	array of size 2 The support of the vector in z , i.e., the vector z is non-zero only in elements <i>isuppz</i> [0] and <i>isuppz</i> [1].
<i>nrminv</i>	$nrminv = 1/\text{SQRT}(ztz)$
<i>resid</i>	The residual of the FP vector.

$resid = ABS(\text{mingma}) / \text{SQRT}(ztz)$

rqcorr

The Rayleigh Quotient correction to *lambda*.

?laref

Applies Householder reflectors to matrices on either their rows or columns.

Syntax

```
void slaref (char *type , float *a , MKL_INT *lda , MKL_INT *wantz , float *z ,
MKL_INT *ldz , MKL_INT *block , MKL_INT *irow1 , MKL_INT *icoll , MKL_INT *istart ,
MKL_INT *istop , MKL_INT *itmp1 , MKL_INT *itmp2 , MKL_INT *liloz , MKL_INT *lihiz ,
float *vecs , float *v2 , float *v3 , float *t1 , float *t2 , float *t3 );
```

```
void dlaref (char *type , double *a , MKL_INT *lda , MKL_INT *wantz , double *z ,
MKL_INT *ldz , MKL_INT *block , MKL_INT *irow1 , MKL_INT *icoll , MKL_INT *istart ,
MKL_INT *istop , MKL_INT *itmp1 , MKL_INT *itmp2 , MKL_INT *liloz , MKL_INT *lihiz ,
double *vecs , double *v2 , double *v3 , double *t1 , double *t2 , double *t3 );
```

Include Files

- mkl_scalapack.h

Description

The ?laref function applies one or several Householder reflectors of size 3 to one or two matrices (if column is specified) on either their rows or columns.

Input Parameters

<i>type</i>	(global) If <i>type</i> = 'R', apply reflectors to the rows of the matrix (apply from left). Otherwise, apply reflectors to the columns of the matrix. Unchanged on exit.
<i>a</i>	(global) Array of size at least <i>lda</i> * <i>itmp2</i> if <i>type</i> equals 'R' and at least <i>lda</i> * (<i>icoll</i> + (<i>istop</i> - <i>istart</i>)) otherwise. On entry, the matrix to receive the reflections.
<i>lda</i>	(local) On entry, the leading dimension of <i>A</i> ; unchanged on exit.
<i>wantz</i>	(global) If <i>wantz</i> is non-zero, apply any column reflections to <i>Z</i> as well. If <i>wantz</i> equals zero, do no additional work on <i>Z</i> .
<i>z</i>	(global) Array of size at least <i>ldz</i> * (<i>icoll</i> + (<i>istop</i> - <i>istart</i>)).

	Referenced only if <i>type</i> differs from 'R'. On entry, the second matrix to receive column reflections.
<i>ldz</i>	(local) On entry, the leading dimension of <i>Z</i> ; unchanged on exit.
<i>block</i>	(global) Non-zero: apply several reflectors at once and read their data from the <i>vecs</i> array; Zero: apply the single reflector given by <i>v2</i> , <i>v3</i> , <i>t1</i> , <i>t2</i> , and <i>t3</i> .
<i>irow1</i>	(local) On entry, the local row element of the matrix <i>A</i> .
<i>icoll</i>	(local) On entry, the local column element of the matrix <i>A</i> .
<i>istart</i>	(global) Specifies the "number" of the first reflector. <i>istart</i> is used as an index into <i>vecs</i> if <i>block</i> is set. <i>istart</i> is ignored if <i>block</i> equals zero.
<i>istop</i>	(global) Specifies the "number" of the last reflector. <i>istop</i> is used as an index into <i>vecs</i> if <i>block</i> is set. <i>istop</i> is ignored if <i>block</i> equals zero.
<i>itmp1</i>	(local) Starting range into <i>A</i> . For rows, this is the local first column. For columns, this is the local first row.
<i>itmp2</i>	(local) Ending range into <i>A</i> . For rows, this is the local last column. For columns, this is the local last row.
<i>liloz</i> , <i>lihiz</i>	(local). Serve the same purpose as <i>itmp1</i> , <i>itmp2</i> but for <i>Z</i> when <i>wantz</i> is set.
<i>vecs</i>	(global) Array of size 3 * <i>n</i> (matrix size). This array holds the size 3 reflectors one after another and is only accessed when <i>block</i> is non-zero
<i>v2,v3,t1,t2,t3</i>	(global) These parameters hold information on a single size 3 Householder reflector and are read when <i>block</i> equals zero, and overwritten when <i>block</i> is non-zero.

Output Parameters

<i>a</i>	On exit, the updated matrix.

<i>z</i>	Changed only if <i>wantz</i> is set. If <i>wantzequals</i> zero, <i>z</i> is not referenced.
<i>irow1</i>	Undefined.
<i>icoll</i>	Undefined.
<i>v2,v3,t1,t2,t3</i>	These parameters are read when <i>blockequals</i> zero, and overwritten when <i>block</i> is non-zero.

?larrb2

Provides limited bisection to locate eigenvalues for more accuracy.

Syntax

```
void slarrb2(MKL_INT* n, float* d, float* lld, MKL_INT* ifirst, MKL_INT* ilast, float*
rtol1, float* rtol2, MKL_INT* offset, float* w, float* wgap, float* werr, float* work,
MKL_INT* iwork, float* pivmin, float* lgpvmn, float* lgspdm, MKL_INT* twist, MKL_INT*
info);
```

```
void dlarrb2(MKL_INT* n, double* d, double* lld, MKL_INT* ifirst, MKL_INT* ilast,
double* rtol1, double* rtol2, MKL_INT* offset, double* w, double* wgap, double* werr,
double* work, MKL_INT* iwork, double* pivmin, double* lgpvmn, double* lgspdm, MKL_INT*
twist, MKL_INT* info);
```

Include Files

- `mk1_scalapack.h`

Description

Given the relatively robust representation (RRR) LDL^T , `?larrb2` does "limited" bisection to refine the eigenvalues of LDL^T with indices in a given range to more accuracy. Initial guesses for these eigenvalues are input in *w*, the corresponding estimate of the error in these guesses and their gaps are input in *werr* and *wgap*, respectively. During bisection, intervals [*left*, *right*] are maintained by storing their mid-points and semi-widths in the arrays *w* and *werr* respectively. The range of indices is specified by the *ifirst*, *ilast*, and *offset* parameters, as explained in [Input Parameters](#).

NOTE

There are very few minor differences between `larrb` from LAPACK and this current function `?larrb2`. The most important reason for creating this nearly identical copy is profiling: in the ScaLAPACK MRRR algorithm, eigenvalue computation using `?larrb2` is used for refinement in the construction of the representation tree, as opposed to the initial computation of the eigenvalues for the root RRR which uses `?larrb`. When profiling, this allows an easy quantification of refinement work vs. computing eigenvalues of the root.

Input Parameters

<i>n</i>	The order of the matrix.
<i>d</i>	Array of size <i>n</i> .

	The n diagonal elements of the diagonal matrix D .
<i>lld</i>	Array of size $n-1$. The $(n-1)$ elements $l_{i+1} * l_{i+1} * d[i]$, $i=0, \dots, n-2$.
<i>ifirst</i>	The index of the first eigenvalue to be computed.
<i>ilast</i>	The index of the last eigenvalue to be computed.
<i>rtol1, rtol2</i>	Tolerance for the convergence of the bisection intervals. An interval $[left, right]$ has converged if $right - left < \max (rtol1 * gap, rtol2 * \max(left , right))$ where gap is the (estimated) distance to the nearest eigenvalue.
<i>offset</i>	Offset for the arrays w , $wgap$ and $werr$, i.e., the elements indexed $ifirst - offset - 1$ through $ilast - offset - 1$ of these arrays are to be used.
<i>w</i>	Array of size n On input, $w[ifirst - offset - 1]$ through $w[ilast - offset - 1]$ are estimates of the eigenvalues of LDL^T indexed $ifirst$ through $ilast$.
<i>wgap</i>	Array of size $n-1$. On input, the (estimated) gaps between consecutive eigenvalues of LDL^T , i.e., $wgap[I - offset - 1]$ is the gap between eigenvalues I and $I + 1$. Note that if $ifirst = ilast$ then $wgap[ifirst - offset - 1]$ must be set to zero.
<i>werr</i>	Array of size n . On input, $werr[ifirst - offset - 1]$ through $werr[ilast - offset - 1]$ are the errors in the estimates of the corresponding elements in w .
<i>work</i>	(workspace) array of size $4*n$. Workspace.
<i>iwork</i>	(workspace) array of size $2*n$. Workspace.
<i>pivmin</i>	The minimum pivot in the Sturm sequence.
<i>lgpvmn</i>	Logarithm of <i>pivmin</i> , precomputed.
<i>lgspdm</i>	Logarithm of the spectral diameter, precomputed.
<i>twist</i>	The twist index for the twisted factorization that is used for the <i>negcount</i> . $twist = n$: Compute <i>negcount</i> from $LDL^T - \lambda I = L_+ D_+ L_+^T$ $twist = 1$: Compute <i>negcount</i> from $LDL^T - \lambda I = U \cdot D \cdot U^T$ $twist = r, 1 < r < n$: Compute <i>negcount</i> from $LDL^T - \lambda I = N_r \Delta_r N_r^T$

OUTPUT Parameters

<i>w</i>	On output, the eigenvalue estimates in <i>w</i> are refined.
<i>wgap</i>	On output, the eigenvalue gaps in <i>wgap</i> are refined.
<i>werr</i>	On output, the errors in <i>werr</i> are refined.
<i>info</i>	Error flag.

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

?larrd2

Computes the eigenvalues of a symmetric tridiagonal matrix to suitable accuracy.

Syntax

```
void slarrd2(char* range, char* order, MKL_INT* n, float* vl, float* vu, MKL_INT* il,
MKL_INT* iu, float* gers, float* reltol, float* d, float* e, float* e2, float* pivmin,
MKL_INT* nsplit, MKL_INT* isplit, MKL_INT* m, float* w, float* werr, float* wl, float*
wu, MKL_INT* iblock, MKL_INT* indexw, float* work, MKL_INT* iwork, MKL_INT* dol,
MKL_INT* dou, MKL_INT* info);
```

```
void dlarrd2(char* range, char* order, MKL_INT* n, double* vl, double* vu, MKL_INT*
il, MKL_INT* iu, double* gers, double* reltol, double* d, double* e, double* e2,
double* pivmin, MKL_INT* nsplit, MKL_INT* isplit, MKL_INT* m, double* w, double* werr,
double* wl, double* wu, MKL_INT* iblock, MKL_INT* indexw, double* work, MKL_INT*
iwork, MKL_INT* dol, MKL_INT* dou, MKL_INT* info);
```

Include Files

- `mkl_scalapack.h`

Description

?larrd2 computes the eigenvalues of a symmetric tridiagonal matrix *T* to limited initial accuracy. This is an auxiliary code to be called from [larre2a](#).

?larrd2 has been created using the LAPACK code `larrd` which itself stems from [stebz](#). The motivation for creating ?larrd2 is efficiency: When computing eigenvalues in parallel and the input tridiagonal matrix splits into blocks, ?larrd2 can skip over blocks which contain none of the eigenvalues from DOL to DOU for which the processor responsible. In extreme cases (such as large matrices consisting of many blocks of small size like 2x2), the gain can be substantial.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Optimization Notice

Notice revision #20110804

Input Parameters

<i>range</i>	= 'A': ("All") all eigenvalues will be found. = 'V': ("Value") all eigenvalues in the half-open interval (<i>vl</i>, <i>vu</i>] will be found. = 'I': ("Index") eigenvalues of the entire matrix with the indices in a given range will be found.
<i>order</i>	= 'B': ("By Block") the eigenvalues will be grouped by split-off block (see <i>iblock</i>, <i>isplit</i>) and ordered from smallest to largest within the block. = 'E': ("Entire matrix") the eigenvalues for the entire matrix will be ordered from smallest to largest.
<i>n</i>	The order of the tridiagonal matrix <i>T</i> . $n \geq 0$.
<i>vl</i> , <i>vu</i>	If <i>range</i>='V', the lower and upper bounds of the interval to be searched for eigenvalues. Eigenvalues less than or equal to <i>vl</i>, or greater than <i>vu</i>, will not be returned. $vl < vu$. Not referenced if <i>range</i> = 'A' or 'I'.
<i>il</i> , <i>iu</i>	If <i>range</i>='I', the indices (in ascending order) of the smallest eigenvalue, to be returned in <i>w</i>[<i>il</i>-1], and largest eigenvalue, to be returned in <i>w</i>[<i>iu</i>-1]. $1 \leq il \leq iu \leq n$, if $n > 0$; $il = 1$ and $iu = 0$ if $n = 0$. Not referenced if <i>range</i> = 'A' or 'V'.
<i>gers</i>	Array of size $2*n$ The <i>n</i> Gerschgorin intervals (the <i>i</i>-th Gerschgorin interval is (<i>gers</i>[$2*i-2$], <i>gers</i>[$2*i-1$])).
<i>reltol</i>	The minimum relative width of an interval. When an interval is narrower than <i>reltol</i> times the larger (in magnitude) endpoint, then it is considered to be sufficiently small, i.e., converged. Note: this should always be at least radix*machine epsilon.
<i>d</i>	Array of size <i>n</i> The <i>n</i> diagonal elements of the tridiagonal matrix <i>T</i>.
<i>e</i>	Array of size <i>n</i>-1 The (<i>n</i>-1) off-diagonal elements of the tridiagonal matrix <i>T</i>.
<i>e2</i>	Array of size <i>n</i>-1 The (<i>n</i>-1) squared off-diagonal elements of the tridiagonal matrix <i>T</i>.
<i>pivmin</i>	The minimum pivot allowed in the sturm sequence for <i>T</i> .
<i>nsplit</i>	The number of diagonal blocks in the matrix <i>T</i> .

$1 \leq nsplit \leq n$.

isplit

Array of size n

The splitting points, at which T breaks up into submatrices.

The first submatrix consists of rows/columns 1 to *isplit*[0], the second of rows/columns *isplit*[0]+1 through *isplit*[1], etc., and the *nsplit*-th submatrix consists of rows/columns *isplit*[*nsplit*-2]+1 through *isplit*[*nsplit*-1]= n .

(Only the first *nsplit* elements will actually be used, but since the user cannot know a priori what value *nsplit* will have, n words must be reserved for *isplit*.)

work

(workspace) Array of size $4*n$

iwork

(workspace) Array of size $3*n$

dol, dou

Specifying an index range *dol:dou* allows the user to work on only a selected part of the representation tree.

Otherwise, the setting *dol*=1, *dou*= n should be applied.

Note that *dol* and *dou* refer to the order in which the eigenvalues are stored in W .

OUTPUT Parameters

m

The actual number of eigenvalues found. $0 \leq m \leq n$.

(See also the description of *info*=2,3.)

w

Array of size n

On exit, the first m elements of *w* will contain the eigenvalue approximations. ?larrrd2 computes an interval $I_j = (a_j, b_j]$ that includes eigenvalue j . The eigenvalue approximation is given as the interval midpoint $w[j-1] = (a_j + b_j)/2$. The corresponding error is bounded by $werr[j-1] = \text{abs}(a_j - b_j)/2$.

werr

Array of size n

The error bound on the corresponding eigenvalue approximation in *w*.

wl, wu

The interval (*wl*, *wu*] contains all the wanted eigenvalues.

If *range*='V', then *wl*=*vl* and *wu*=*vu*.

If *range*='A', then *wl* and *wu* are the global Gerschgorin bounds on the spectrum.

If *range*='I', then *wl* and *wu* are computed by SLAEBZ from the index range specified.

iblock

Array of size n

At each row/column j where $e[j-1]$ is zero or small, the matrix T is considered to split into a block diagonal matrix. On exit, if $info = 0$, $iblock[i]$ specifies to which block (from 0 to the number of blocks minus one) the eigenvalue $w[i]$ belongs. (`?larre2` may use the remaining $n-m$ elements as workspace.)

indexw

Array of size n

The indices of the eigenvalues within each block (submatrix); for example, $indexw[i] = j$ and $iblock[i] = k$ imply that the $(i+1)$ -th eigenvalue $w[i]$ is the j -th eigenvalue in block k .

info

= 0: successful exit

< 0: if $info = -i$, the i -th argument had an illegal value

> 0: some or all of the eigenvalues failed to converge or were not computed:

- = 1 or 3: Bisection failed to converge for some eigenvalues; these eigenvalues are flagged by a negative block number. The effect is that the eigenvalues may not be as accurate as the absolute and relative tolerances.
- = 2 or 3: $range='I'$ only: Not all of the eigenvalues $il:iu$ were found.
- = 4: $range='I'$, and the Gershgorin interval initially used was too small. No eigenvalues were computed.

Include Files

- `mk1_scalapack.h`

Description

To find the desired eigenvalues of a given real symmetric tridiagonal matrix T , `?larre2` sets, via `?larra`, "small" off-diagonal elements to zero. For each block T_i , it finds

- a suitable shift at one end of the block's spectrum,
- the root RRR, $T_i - \sigma_i I = L_i D_i L_i^T$, and
- eigenvalues of each $L_i D_i L_i^T$.

The representations and eigenvalues found are then returned to `?stegr2` to compute the eigenvectors T .

`?larre2` is more suitable for parallel computation than the original LAPACK code for computing the root RRR and its eigenvalues. When computing eigenvalues in parallel and the input tridiagonal matrix splits into blocks, `?larre2` can skip over blocks which contain none of the eigenvalues from d_{ol} to d_{ou} for which the processor is responsible. In extreme cases (such as large matrices consisting of many blocks of small size, e.g. 2x2), the gain can be substantial.

Notice revision #20110804

Input Parameters

<i>range</i>	= 'A': ("All") all eigenvalues will be found. = 'V': ("Value") all eigenvalues in the half-open interval $(v_l, v_u]$ will be found. = 'I': ("Index") eigenvalues of the entire matrix with the indices in a given range will be found.
<i>n</i>	The order of the matrix. $n > 0$.
<i>v_l, v_u</i>	If <i>range</i>='V', the lower and upper bounds for the eigenvalues. Eigenvalues less than or equal to v_l, or greater than v_u, will not be returned. $v_l < v_u$.
<i>il, iu</i>	If <i>range</i>='I', the indices (in ascending order) of the smallest eigenvalue, to be returned in $w[il-1]$, and largest eigenvalue, to be returned in $w[iu-1]$. $1 \leq il \leq iu \leq n$.
<i>d</i>	Array of size n The n diagonal elements of the tridiagonal matrix T.
<i>e</i>	Array of size n The first $(n-1)$ entries contain the subdiagonal elements of the tridiagonal matrix T; $e[n-1]$ need not be set.
<i>e2</i>	Array of size n The first $(n-1)$ entries contain the squares of the subdiagonal elements of the tridiagonal matrix T; $e2[n-1]$ need not be set.

<i>rtol1, rtol2</i>	Parameters for bisection. An interval $[left, right]$ has converged if $right-left < \max(rtol1*gap, rtol2*\max(left , right))$
<i>spltol</i>	The threshold for splitting.
<i>dol, dou</i>	Specifying an index range $dol:dou$ allows the user to work on only a selected part of the representation tree. Otherwise, the setting $dol=1, dou=n$ should be applied. Note that dol and dou refer to the order in which the eigenvalues are stored in w .
<i>work</i>	Workspace array of size $6*n$
<i>iwork</i>	Workspace array of size $5*n$

OUTPUT Parameters

<i>vl, vu</i>	If $range='I'$ or $'A'$, $?larre2$ contains bounds on the desired part of the spectrum.
<i>d</i>	The n diagonal elements of the diagonal matrices D_i .
<i>e</i>	e contains the subdiagonal elements of the unit bidiagonal matrices L_j . The entries $e[isplit[i]], 0 \leq i < nsplit$, contain the base points σ_{i+1} on output.
<i>e2</i>	The entries $e2[isplit[i]], 0 \leq i < nsplit$, are set to zero.
<i>nsplit</i>	The number of blocks T splits into. $1 \leq nsplit \leq n$.
<i>isplit</i>	Array of size n The splitting points, at which T breaks up into blocks. The first block consists of rows/columns 1 to $isplit[0]$, the second of rows/columns $isplit[0]+1$ through $isplit[1]$, etc., and the $nsplit$ -th block consists of rows/columns $isplit[nsplit-2]+1$ through $isplit[nsplit-1]=n$.
<i>m</i>	The total number of eigenvalues (of all $L_i D_i L_i^T$) found.
<i>w</i>	Array of size n The first m elements contain the eigenvalues. The eigenvalues of each of the blocks, $L_i D_i L_i^T$, are sorted in ascending order ($?larre2$ may use the remaining $n-m$ elements as workspace). Note that immediately after exiting this function, only the eigenvalues in w with indices in range $dol-1:dou-1$ might rely on this processor when the eigenvalue computation is done in parallel.
<i>werr</i>	Array of size n The error bound on the corresponding eigenvalue in w .

Note that immediately after exiting this function, only the uncertainties in *werr* with indices in range *dol*-1:*dou*-1 might rely on this processor when the eigenvalue computation is done in parallel.

wgap

Array of size *n*

The separation from the right neighbor eigenvalue in *w*.

The gap is only with respect to the eigenvalues of the same block as each block has its own representation tree.

Exception: at the right end of a block we store the left gap

Note that immediately after exiting this function, only the gaps in *wgap* with indices in range *dol*-1:*dou*-1 might rely on this processor when the eigenvalue computation is done in parallel.

iblock

Array of size *n*

The indices of the blocks (submatrices) associated with the corresponding eigenvalues in *w*; *iblock*[*i*]=1 if eigenvalue *w*[*i*] belongs to the first block from the top, *iblock*[*i*]=2 if *w*[*i*] belongs to the second block, and so on.

indexw

Array of size *n*

The indices of the eigenvalues within each block (submatrix); for example, *indexw*[*i*]= 10 and *iblock*[*i*]=2 imply that the (*i*+1)-th eigenvalue *w*[*i*] is the 10th eigenvalue in block 2.

gers

Array of size 2**n*

The *n* Gerschgorin intervals (the *i*-th Gerschgorin interval is (*gers*[2**i*-2], *gers*[2**i*-1])).

pivmin

The minimum pivot in the sturm sequence for *T*.

info

Include Files

- mkl_scalapack.h

Description

To find the desired eigenvalues of a given real symmetric tridiagonal matrix T , ?larre2a sets any "small" off-diagonal elements to zero, and for each unreduced block T_i , it finds

- a suitable shift at one end of the block's spectrum,
- the base representation, $T_i - \sigma_i I = L_i D_i L_i^T$, and
- eigenvalues of each $L_i D_i L_i^T$.

NOTE

The algorithm obtains a crude picture of all the wanted eigenvalues (as selected by *range*). However, to reduce work and improve scalability, only the eigenvalues *dol* to *dou* are refined. Furthermore, if the matrix splits into blocks, RRRs for blocks that do not contain eigenvalues from *dol* to *dou* are skipped. The DQDS algorithm (function ?lasq2) is not used, unlike in the sequential case. Instead, eigenvalues are computed in parallel to some figures using bisection.

Notice revision #20110804

Input Parameters

<i>range</i>	= 'A': ("All") all eigenvalues will be found. = 'V': ("Value") all eigenvalues in the half-open interval (<i>vl</i>, <i>vu</i>] will be found. = 'I': ("Index") eigenvalues of the entire matrix with the indices in a given range will be found.
<i>n</i>	The order of the matrix. $n > 0$.
<i>vl</i> , <i>vu</i>	If <i>range</i>='V', the lower and upper bounds for the eigenvalues. Eigenvalues less than or equal to <i>vl</i>, or greater than <i>vu</i>, will not be returned. $vl < vu$. If <i>range</i>='I' or ='A', <code>?larre2a</code> computes bounds on the desired part of the spectrum.
<i>il</i> , <i>iu</i>	If <i>range</i>='I', the indices (in ascending order) of the smallest eigenvalue, to be returned in <i>w</i>[<i>il</i>-1], and largest eigenvalue, to be returned in <i>w</i>[<i>iu</i>-1]. $1 \leq il \leq iu \leq n$.
<i>d</i>	Array of size <i>n</i> On entry, the <i>n</i> diagonal elements of the tridiagonal matrix <i>T</i>.
<i>e</i>	Array of size <i>n</i> The first (<i>n</i>-1) entries contain the subdiagonal elements of the tridiagonal matrix <i>T</i>; <i>e</i>[<i>n</i>-1] need not be set.
<i>e2</i>	Array of size <i>n</i> The first (<i>n</i>-1) entries contain the squares of the subdiagonal elements of the tridiagonal matrix <i>T</i>; <i>e2</i>[<i>n</i>-1] need not be set.
<i>rtol1</i> , <i>rtol2</i>	Parameters for bisection. An interval [<i>left</i>,<i>right</i>] has converged if $right - left < \max(rtol1*gap, rtol2*\max(left , right))$
<i>spltol</i>	The threshold for splitting.
<i>dol</i> , <i>dou</i>	If the user wants to work on only a selected part of the representation tree, he can specify an index range <i>dol</i>:<i>dou</i>. Otherwise, the setting <i>dol</i>=1, <i>dou</i>=<i>n</i> should be applied. Note that <i>dol</i> and <i>dou</i> refer to the order in which the eigenvalues are stored in <i>w</i>.
<i>work</i>	Workspace array of size $6*n$
<i>iwork</i>	Workspace array of size $5*n$
<i>minrgp</i>	The minimum relative gap threshold to decide whether an eigenvalue or a cluster boundary is reached.

OUTPUT Parameters

<i>vl, vu</i>	If <i>range</i>='V', the lower and upper bounds for the eigenvalues. Eigenvalues less than or equal to <i>vl</i>, or greater than <i>vu</i>, are not returned. $vl < vu$. If <i>range</i>='I' or <i>range</i>='A', ?larre2a computes bounds on the desired part of the spectrum.
<i>d</i>	The n diagonal elements of the diagonal matrices D_i .
<i>e</i>	<i>e</i> contains the subdiagonal elements of the unit bidiagonal matrices L_i . The entries $e[isplit[j]]$, $0 \leq j < nsplit$, contain the base points σ_{i+1} on output.
<i>e2</i>	The entries $e2[isplit[i]]$, $0 \leq j < nsplit$ have been set to zero.
<i>nsplit</i>	The number of blocks T splits into. $1 \leq nsplit \leq n$.
<i>isplit</i>	Array of size n The splitting points, at which T breaks up into blocks. The first block consists of rows/columns 1 to $isplit[0]$, the second of rows/columns $isplit[0]+1$ through $isplit[1]$, etc., and the $nsplit$-th block consists of rows/columns $isplit[nsplit-2]+1$ through $isplit[nsplit-1]=n$.
<i>m</i>	The total number of eigenvalues (of all $L_i D_i L_i^T$) found.
<i>needil, neediu</i>	The indices of the leftmost and rightmost eigenvalues of the root node RRR which are needed to accurately compute the relevant part of the representation tree.
<i>w</i>	Array of size n The first m elements contain the eigenvalues. The eigenvalues of each of the blocks, $L_i D_i L_i^T$, are sorted in ascending order (?larre2a may use the remaining $n-m$ elements as workspace). Note that immediately after exiting this function, only the eigenvalues in w with indices in range $dol-1:dou-1$ rely on this processor because the eigenvalue computation is done in parallel.
<i>werr</i>	Array of size n The error bound on the corresponding eigenvalue in w. Note that immediately after exiting this function, only the uncertainties in $werr$ with indices in range $dol-1:dou-1$ are reliable on this processor because the eigenvalue computation is done in parallel.
<i>wgap</i>	Array of size n The separation from the right neighbor eigenvalue in w. The gap is only with respect to the eigenvalues of the same block as each block has its own representation tree. Exception: at the right end of a block we store the left gap

Note that immediately after exiting this function, only the gaps in *wgap* with indices in range *dol*-1:*dou*-1 are reliable on this processor because the eigenvalue computation is done in parallel.

iblock

Array of size *n*

The indices of the blocks (submatrices) associated with the corresponding eigenvalues in *w*; *iblock*[*i*]=1 if eigenvalue *w*[*i*] belongs to the first block from the top, *iblock*[*i*]=2 if *w*[*i*] belongs to the second block, and so on.

indexw

Array of size *n*

The indices of the eigenvalues within each block (submatrix); for example, *indexw*[*i*]= 10 and *iblock*[*i*]=2 imply that the (*i*+1)-th eigenvalue *w*[*i*] is the 10th eigenvalue in block 2.

gers

Array of size 2**n*

The *n* Gerschgorin intervals (the *i*-th Gerschgorin interval is (*gers*[2**i*-2], *gers*[2**i*-1])).

pivmin

The minimum pivot in the sturm sequence for *T*.

info

= 0: successful exit

> 0: A problem occurred in ?larre2a.

< 0: One of the called functions signaled an internal problem. Needs inspection of the corresponding parameter *info* for further information.

==1: Problem in ?larrd2.

==2: Not enough internal iterations to find base representation.

==3: Problem in ?larreb2 when computing the refined root representation.

==4: Problem in ?larreb2 when performing bisection on the desired part of the spectrum.

MKL_INT* trymid, double* spdiam, double* clgapl, double* clgapr, double* pivmin,
double* sigma, double* dplus, double* lplus, double* work, MKL_INT* info);
```

Include Files

- `mkl_scalapack.h`

Description

Given the initial representation LDL^T and its cluster of close eigenvalues (in a relative measure), defined by the indices of the first and last eigenvalues in the cluster, `?larrf2` finds a new relatively robust representation $LDL^T - \sigma I = L_+ D_+ L_+^T$ such that at least one of the eigenvalues of $L_+ D_+ L_+^T$ is relatively isolated.

This is an enhanced version of `?larrf` that also tries shifts in the middle of the cluster, should there be a large gap, in order to break large clusters into at least two pieces.

Input Parameters

<i>n</i>	The order of the matrix (subblock, if the matrix was split).
<i>d</i>	Array of size <i>n</i> The <i>n</i> diagonal elements of the diagonal matrix <i>D</i> .
<i>l</i>	Array of size <i>n</i> -1 The (<i>n</i> -1) subdiagonal elements of the unit bidiagonal matrix <i>L</i> .
<i>ld</i>	Array of size <i>n</i> -1 The (<i>n</i> -1) elements <i>l</i> [<i>i</i>]* <i>d</i> [<i>i</i>].
<i>clstrt</i>	The index of the first eigenvalue in the cluster.
<i>clend</i>	The index of the last eigenvalue in the cluster.
<i>clmid1, clmid2</i>	The index of a middle eigenvalue pair with large gap.
<i>w</i>	Array of size $\geq (clend-clstrt+1)$ The eigenvalue approximations of LDL^T in ascending order. <i>w</i> [<i>clstrt</i> - 1] through <i>w</i> [<i>clend</i> - 1] form the cluster of relatively close eigenvalues.
<i>wgap</i>	Array of size $\geq (clend-clstrt+1)$ The separation from the right neighbor eigenvalue in <i>w</i> .
<i>werr</i>	Array of size $\geq (clend-clstrt+1)$ <i>werr</i> contains the semiwidth of the uncertainty interval of the corresponding eigenvalue approximation in <i>w</i> .
<i>spdiam</i>	Estimate of the spectral diameter obtained from the Gerschgorin intervals
<i>clgapl, clgapr</i>	Absolute gap on each end of the cluster. Set by the calling function to protect against shifts too close to eigenvalues outside the cluster.
<i>pivmin</i>	The minimum pivot allowed in the Sturm sequence.
<i>work</i>	Workspace array of size $2*n$

OUTPUT Parameters

<i>wgap</i>	Contains refined values of its input approximations. Very small gaps are unchanged.
<i>sigma</i>	The shift (σ) used to form $L_+D_+L_+^T$.
<i>dplus</i>	Array of size n The n diagonal elements of the diagonal matrix D_+ .
<i>lplus</i>	Array of size $n-1$ The first $(n-1)$ elements of <i>lplus</i> contain the subdiagonal elements of the unit bidiagonal matrix L_+ .

Include Files

- mkl_scalapack.h

Description

?larrv2 computes the eigenvectors of the tridiagonal matrix $T = LDL^T$ given L , D and approximations to the eigenvalues of LDL^T . The input eigenvalues should have been computed by [larre2a](#) or by previous calls to ?larrv2.

The major difference between the parallel and the sequential construction of the representation tree is that in the parallel case, not all eigenvalues of a given cluster might be computed locally. Other processors might "own" and refine part of an eigenvalue cluster. This is crucial for scalability. Thus there might be communication necessary before the current level of the representation tree can be parsed.

Please note:

- The calling sequence has two additional integer parameters, *dol* and *dou*, that should satisfy $m \geq dou \geq dol \geq 1$. These parameters are only relevant when both eigenvalues and eigenvectors are computed (stegr2b parameter *jobz* = 'V'). ?larrv2 only computes the eigenvectors corresponding to eigenvalues

dol through *dou* in *w*. (That is, instead of computing the eigenvectors belonging to $w[0]$ through $w[m-1]$, only the eigenvectors belonging to eigenvalues $w[dol - 1]$ through $w[dou - 1]$ are computed. In this case, only the eigenvalues *dol:dou* are guaranteed to be accurately refined to all figures by Rayleigh-Quotient iteration.

- The additional arguments *vstart*, *finish*, *ndepth*, *parity*, *zoffset* are included as a thread-safe implementation equivalent to save variables. These variables store details about the local representation tree which is computed layerwise. For scalability reasons, eigenvalues belonging to the locally relevant representation tree might be computed on other processors. These need to be communicated before the inspection of the RRRs can proceed on any given layer. Note that only when the variable *finish* is non-zero, the computation has ended. All eigenpairs between *dol* and *dou* have been computed. *m* is set to *dou* - *dol* + 1.
- `?larrv2` needs more workspace in *z* than the sequential `slarrv`. It is used to store the conformal embedding of the local representation tree.

Notice revision #20110804

Input Parameters

<i>n</i>	The order of the matrix. $n \geq 0$.
<i>vl</i> , <i>vu</i>	Lower and upper bounds of the interval that contains the desired eigenvalues. $vl < vu$. Needed to compute gaps on the left or right end of the extremal eigenvalues in the desired range. <i>vu</i> is currently not used but kept as parameter in case needed.
<i>d</i>	Array of size <i>n</i> The <i>n</i> diagonal elements of the diagonal matrix <i>d</i> . On exit, <i>d</i> is overwritten.
<i>l</i>	Array of size <i>n</i> The (<i>n</i> -1) subdiagonal elements of the unit bidiagonal matrix <i>L</i> are in elements 0 to <i>n</i> -2 of <i>l</i> (if the matrix is not split.) At the end of each block is stored the corresponding shift as given by <code>?larre</code> . On exit, <i>l</i> is overwritten.
<i>pivmin</i>	The minimum pivot allowed in the sturm sequence.
<i>isplit</i>	Array of size <i>n</i> The splitting points, at which the matrix <i>T</i> breaks up into blocks. The first block consists of rows/columns 1 to <i>isplit</i> [0], the second of rows/columns <i>isplit</i> [0] + 1 through <i>isplit</i> [1], etc.
<i>m</i>	The total number of input eigenvalues. $0 \leq m \leq n$.

<i>dol, dou</i>	If you want to compute only selected eigenvectors from all the eigenvalues supplied, you can specify an index range <i>dol:dou</i>. Or else the setting <i>dol=1, dou=m</i> should be applied. Note that <i>dol</i> and <i>dou</i> refer to the order in which the eigenvalues are stored in <i>w</i>. If you want to compute only selected eigenpairs, the columns <i>dol-1</i> to <i>dou+1</i> of the eigenvector space <i>Z</i> contain the computed eigenvectors. All other columns of <i>Z</i> are set to zero. If <i>dol > 1</i>, then $Z(:, dol-1-zoffset)$ is used. If <i>dou < m</i>, then $Z(:, dou+1-zoffset)$ is used.
<i>needil, neediu</i>	Describe which are the left and right outermost eigenvalues that still need to be included in the computation. These indices indicate whether eigenvalues from other processors are needed to correctly compute the conformally embedded representation tree. When $dol \leq needil \leq neediu \leq dou$, all required eigenvalues are local to the processor and no communication is required to compute its part of the representation tree.
<i>minrgp</i>	The minimum relative gap threshold to decide whether an eigenvalue or a cluster boundary is reached.
<i>rtol1, rtol2</i>	Parameters for bisection. An interval $[left, right]$ has converged if $right-left < \max(rtol1*gap, rtol2*\max(left , right))$
<i>w</i>	Array of size <i>n</i> The first <i>m</i> elements of <i>w</i> contain the approximate eigenvalues for which eigenvectors are to be computed. The eigenvalues should be grouped by split-off block and ordered from smallest to largest within the block. (The output array <i>w</i> from <code>?stegr2a</code> is expected here.) Furthermore, they are with respect to the shift of the corresponding root representation for their block.
<i>werr</i>	Array of size <i>n</i> The first <i>m</i> elements contain the semiwidth of the uncertainty interval of the corresponding eigenvalue in <i>w</i>.
<i>wgap</i>	Array of size <i>n</i> The separation from the right neighbor eigenvalue in <i>w</i>.
<i>iblock</i>	Array of size <i>n</i> The indices of the blocks (submatrices) associated with the corresponding eigenvalues in <i>w</i>; <i>iblock</i>[<i>i</i>]=1 if eigenvalue <i>w</i>[<i>i</i>] belongs to the first block from the top, <i>iblock</i>[<i>i</i>]=2 if <i>w</i>[<i>i</i>] belongs to the second block, and so on.
<i>indexw</i>	Array of size <i>n</i> The indices of the eigenvalues within each block (submatrix). For example: <i>indexw</i>[<i>i</i>]= 10 and <i>iblock</i>[<i>i</i>]=2 imply that the (<i>i</i>+1)-th eigenvalue <i>w</i>[<i>i</i>] is the 10th eigenvalue in block 2.
<i>gers</i>	Array of size $2*n$

The n Gerschgorin intervals (the i -th Gerschgorin interval is ($gers[2*i-2]$, $gers[2*i-1]$)). The Gerschgorin intervals should be computed from the original unshifted matrix.

Not used but kept as parameter for possible future use.

<i>sdiam</i>	Array of size n The spectral diameters for all unreduced blocks.
<i>ldz</i>	The leading dimension of the array z . $ldz \geq 1$, and if <i>stegr2b</i> parameter <i>jobz</i> = 'V', $ldz \geq \max(1, n)$.
<i>work</i>	(workspace) array of size $12*n$
<i>iwork</i>	(workspace) Array of size $7*n$
<i>vstart</i>	Non-zero on initialization, set to zero afterwards.
<i>finish</i>	A flag that indicates whether all eigenpairs have been computed.
<i>maxcls</i>	The largest cluster worked on by this processor in the representation tree.
<i>ndepth</i>	The current depth of the representation tree. Set to zero on initial pass, changed when the deeper levels of the representation tree are generated.
<i>parity</i>	An internal parameter needed for the storage of the clusters on the current level of the representation tree.
<i>zoffset</i>	Offset for storing the eigenpairs when z is distributed in 1D-cyclic fashion.

OUTPUT Parameters

<i>needil, neediu</i>	
<i>w</i>	Unshifted eigenvalues for which eigenvectors have already been computed.
<i>werr</i>	Contains refined values of its input approximations.
<i>wgap</i>	Contains refined values of its input approximations. Very small gaps are changed.
<i>z</i>	Array of size $ldz * \max(1, m)$ If <i>info</i> = 0, the first m columns of the matrix Z , stored in the array z , contain the orthonormal eigenvectors of the matrix T corresponding to the input eigenvalues, with the i -th column of Z holding the eigenvector associated with $w[i - 1]$. In the distributed version, only a subset of columns is accessed, see <i>dol</i> , <i>dou</i> , and <i>zoffset</i> .
<i>isuppz</i>	Array of size $2*\max(1, m)$ The support of the eigenvectors in z , i.e., the indices indicating the non-zero elements in z . The i -th eigenvector is non-zero only in elements $isuppz[2*i-2]$ through $isuppz[2*i-1]$.

<i>vstart</i>	Non-zero on initialization, set to zero afterwards.
<i>finish</i>	A flag that indicates whether all eigenpairs have been computed.
<i>maxcls</i>	The largest cluster worked on by this processor in the representation tree.
<i>ndepth</i>	The current depth of the representation tree. Set to zero on initial pass, changed when the deeper levels of the representation tree are generated.
<i>parity</i>	An internal parameter needed for the storage of the clusters on the current level of the representation tree.
<i>info</i>	= 0: successful exit > 0: A problem occurred in ?larrv2. < 0: One of the called functions signaled an internal problem. Needs inspection of the corresponding parameter <i>info</i> for further information. =-1: Problem in ?larreb2 when refining a child's eigenvalues. =-2: Problem in ?larref2 when computing the RRR of a child. When a child is inside a tight cluster, it can be difficult to find an RRR. A partial remedy from the user's point of view is to make the parameter <i>minrgp</i> smaller and recompile. However, as the orthogonality of the computed vectors is proportional to $1/\text{minrgp}$, be aware that decreasing <i>minrgp</i> might be reduce precision. =-3: Problem in ?larreb2 when refining a single eigenvalue after the Rayleigh correction was rejected. = 5: The Rayleigh Quotient Iteration failed to converge to full accuracy.

?lasorte

Sorts eigenpairs by real and complex data types.

Syntax

```
void slasorte (float *s , MKL_INT *lds , MKL_INT *j , float *out , MKL_INT *info );
void dlasorte (double *s , MKL_INT *lds , MKL_INT *j , double *out , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The ?lasortefunction sorts eigenpairs so that real eigenpairs are together and complex eigenpairs are together. This helps to employ 2x2 shifts easily since every second subdiagonal is guaranteed to be zero. This function does no parallel work and makes no calls.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

<i>s</i>	(local) Array of size <i>lds</i> . On entry, a matrix already in Schur form.
<i>lds</i>	(local) On entry, the leading dimension of the array <i>s</i> ; unchanged on exit.
<i>j</i>	(local) On entry, the order of the matrix <i>S</i> ; unchanged on exit.
<i>out</i>	(local) Array of size $2*j$. The work buffer required by the function.
<i>info</i>	(local) Set, if the input matrix had an odd number of real eigenvalues and things could not be paired or if the input matrix <i>S</i> was not originally in Schur form. 0 indicates successful completion.

Output Parameters

<i>s</i>	On exit, the diagonal blocks of <i>S</i> have been rewritten to pair the eigenvalues. The resulting matrix is no longer similar to the input.
<i>out</i>	Work buffer.

?lasrt2

Sorts numbers in increasing or decreasing order.

Syntax

```
void slasrt2 (char *id , MKL_INT *n , float *d , MKL_INT *key , MKL_INT *info );
void dlasrt2 (char *id , MKL_INT *n , double *d , MKL_INT *key , MKL_INT *info );
```

Include Files

- `mkl_scalapack.h`

Description

The `?lasrt2` function is modified LAPACK function `?lasrt`, which sorts the numbers in d in increasing order (if $id = 'I'$) or in decreasing order (if $id = 'D'$). It uses Quick Sort, reverting to Insertion Sort on arrays of size ≤ 20 . The size of `STACK` limits n to about 2^{32} .

Input Parameters

id	= 'I': sort d in increasing order; = 'D': sort d in decreasing order.
n	The length of the array d .
d	Array of size n. On entry, the array to be sorted.
key	Array of size n. On entry, key contains a key to each of the entries in d. Typically, $key[i] = i+1$ for all $i = 0, \dots, n-1$.

Output Parameters

d	On exit, d has been sorted into increasing order $(d[0] \leq \dots \leq d[n-1])$ or into decreasing order $(d[0] \geq \dots \geq d[n-1])$, depending on id.
$info$	= 0: successful exit < 0: if $info = -i$, the i-th argument had an illegal value.
key	On exit, key is permuted in exactly the same manner as d was permuted from input to output. Therefore, if $key[i] = i+1$ for all $i = 0, \dots, n-1$ on input, $d[i]$ on output equals $d[key[i]-1]$ on input.

?stegr2

Computes selected eigenvalues and eigenvectors of a real symmetric tridiagonal matrix.

Syntax

```
void sstegr2(char* jobz, char* range, MKL_INT* n, float* d, float* e, float* vl,
float* vu, MKL_INT* il, MKL_INT* iu, MKL_INT* m, float* w, float* z, MKL_INT* ldz,
MKL_INT* nzc, MKL_INT* isuppz, float* work, MKL_INT* lwork, MKL_INT* iwork, MKL_INT*
liwork, MKL_INT* dol, MKL_INT* dou, MKL_INT* zoffset, MKL_INT* info);
```

```
void dstegr2(char* jobz, char* range, MKL_INT* n, double* d, double* e, double* vl,
double* vu, MKL_INT* il, MKL_INT* iu, MKL_INT* m, double* w, double* z, MKL_INT* ldz,
MKL_INT* nzc, MKL_INT* isuppz, double* work, MKL_INT* lwork, MKL_INT* iwork, MKL_INT*
liwork, MKL_INT* dol, MKL_INT* dou, MKL_INT* zoffset, MKL_INT* info);
```

Include Files

- mkl_scalapack.h

Description

`?stegr2` computes selected eigenvalues and, optionally, eigenvectors of a real symmetric tridiagonal matrix T . It is invoked in the ScaLAPACK MRRR driver `p?syevr` and the corresponding Hermitian version either when only eigenvalues are to be computed, or when only a single processor is used (the sequential-like case).

`?stegr2` has been adapted from LAPACK's `?stegr`. Please note the following crucial changes.

1. The calling sequence has two additional integer parameters, dol and dou , that should satisfy $m \geq dou \geq dol \geq 1$. `?stegr2` only computes the eigenpairs corresponding to eigenvalues dol through dou in w , indexed $dol-1$ through $dou-1$. (That is, instead of computing the eigenpairs belonging to $w[0]$ through $w[m-1]$, only the eigenvectors belonging to eigenvalues $w[dol-1]$ through $w[dou-1]$ are computed. In this case, only the eigenvalues dol through dou are guaranteed to be fully accurate.
2. m is not the number of eigenvalues specified by $range$, but is $m = dou - dol + 1$. This concerns the case where only eigenvalues are computed, but on more than one processor. Thus, in this case m refers to the number of eigenvalues computed on this processor.
3. The arrays w and z might not contain all the wanted eigenpairs locally, instead this information is distributed over other processors.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

$jobz$	= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.
$range$	= 'A': all eigenvalues will be found. = 'V': all eigenvalues in the half-open interval $(vl, vu]$ will be found. = 'I': eigenvalues of the entire matrix with the indices in a given range will be found.
n	The order of the matrix. $n \geq 0$.
d	Array of size n

	On entry, the n diagonal elements of the tridiagonal matrix T . Overwritten on exit.
e	Array of size n On entry, the $(n-1)$ subdiagonal elements of the tridiagonal matrix T in elements 0 to $n-2$ of e. $e[n-1]$ need not be set on input, but is used internally as workspace. Overwritten on exit.
vl	
vu	If $range='V'$, the lower and upper bounds of the interval to be searched for eigenvalues. $vl < vu$. Not referenced if $range = 'A'$ or $'I'$.
il, iu	If $range='I'$, the indices (in ascending order) of the smallest eigenvalue, to be returned in $w[il-1]$, and largest eigenvalue, to be returned in $w[iu-1]$. $1 \leq il \leq iu \leq n$, if $n > 0$. Not referenced if $range = 'A'$ or $'V'$.
ldz	The leading dimension of the array z . $ldz \geq 1$, and if $jobz = 'V'$, then $ldz \geq \max(1, n)$.
nzc	The number of eigenvectors to be held in the array z, storing the matrix Z. If $range = 'A'$, then $nzc \geq \max(1, n)$. If $range = 'V'$, then $nzc \geq$ the number of eigenvalues in $(vl, vu]$. If $range = 'I'$, then $nzc \geq iu - il + 1$. If $nzc = -1$, then a workspace query is assumed; the function calculates the number of columns of the matrix Z that are needed to hold the eigenvectors. This value is returned as the first entry of the z array, and no error message related to nzc is issued.
$lwork$	The size of the array $work$. $lwork \geq \max(1, 18*n)$ if $jobz = 'V'$, and $lwork \geq \max(1, 12*n)$ if $jobz = 'N'$. If $lwork = -1$, then a workspace query is assumed; the function only calculates the optimal size of the $work$ array, returns this value as the first entry of the $work$ array, and no error message related to $lwork$ is issued.
$liwork$	The size of the array $iwork$. $liwork \geq \max(1, 10*n)$ if the eigenvectors are desired, and $liwork \geq \max(1, 8*n)$ if only the eigenvalues are to be computed. If $liwork = -1$, then a workspace query is assumed; the function only calculates the optimal size of the $iwork$ array, returns this value as the first entry of the $iwork$ array, and no error message related to $liwork$ is issued.
dol, dou	From the eigenvalues $w[0]$ through $w[m-1]$, only eigenvectors $Z(:, dol)$ to $Z(:, dou)$ are computed. If $dol > 1$, then $Z(:, dol-1-zoffset)$ is used and overwritten. If $dou < m$, then $Z(:, dou+1-zoffset)$ is used and overwritten.

zoffset Offset for storing the eigenpairs when *z* is distributed in 1D-cyclic fashion

OUTPUT Parameters

<i>m</i>	Globally summed over all processors, <i>m</i> equals the total number of eigenvalues found. $0 \leq m \leq n$. If <i>range</i> = 'A', <i>m</i> = <i>n</i> , and if <i>range</i> = 'I', <i>m</i> = <i>i</i> _u - <i>i</i> _l +1. The local output equals <i>m</i> = <i>dou</i> - <i>dol</i> + 1.
<i>w</i>	Array of size <i>n</i> The first <i>m</i> elements contain the selected eigenvalues in ascending order. Note that immediately after exiting this function, only the eigenvalues indexed <i>dol</i>-1 through <i>dou</i>-1 are reliable on this processor because the eigenvalue computation is done in parallel. Other processors will hold reliable information on other parts of the <i>w</i> array. This information is communicated in the ScaLAPACK driver.
<i>z</i>	Array of size <i>ldz</i> * max(1,<i>m</i>). If <i>jobz</i> = 'V', and if <i>info</i> = 0, then the first <i>m</i> columns of the matrix <i>Z</i> stored in <i>z</i> contain some of the orthonormal eigenvectors of the matrix <i>T</i> corresponding to the selected eigenvalues, with the <i>i</i>-th column of <i>Z</i> holding the eigenvector associated with <i>w</i>[<i>i</i>-1]. If <i>jobz</i> = 'N', then <i>z</i> is not referenced. Note: the user must ensure that at least max(1,<i>m</i>) columns of the matrix are supplied in the array <i>z</i>; if <i>range</i> = 'V', the exact value of <i>m</i> is not known in advance and can be computed with a workspace query by setting <i>nzc</i> = -1, see below.
<i>isuppz</i>	array of size 2*max(1,<i>m</i>) The support of the eigenvectors in <i>z</i>, i.e., the indices indicating the nonzero elements in <i>z</i>. The <i>i</i>-th computed eigenvector is nonzero only in elements <i>isuppz</i>[2*i-2] through <i>isuppz</i>[2*i-1]. This is relevant in the case when the matrix is split. <i>isuppz</i> is only set if <i>n</i>>2.
<i>work</i>	On exit, if <i>info</i> = 0, <i>work</i> [0] returns the optimal (and minimal) <i>lwork</i> .
<i>iwork</i>	On exit, if <i>info</i> = 0, <i>iwork</i> [0] returns the optimal <i>liwork</i> .
<i>info</i>	On exit, <i>info</i> = 0: successful exit other: if <i>info</i> = -<i>i</i>, the <i>i</i>-th argument had an illegal value if <i>info</i> = 10X, internal error in ?larre2, if <i>info</i> = 20X, internal error in ?larrv. Here, the digit X = ABS(<i>iinfo</i>) < 10, where <i>iinfo</i> is the nonzero error code returned by ?larre2 or ?larrv, respectively.

```

Include Files

- mkl_scalapack.h

Description

?stegr2a computes selected eigenvalues and initial representations needed for eigenvector computations in ?stegr2b. It is invoked in the ScaLAPACK MRRR driver p?syevr and the corresponding Hermitian version when both eigenvalues and eigenvectors are computed in parallel on multiple processors. For this case, ?stegr2a implements the first part of the MRRR algorithm, parallel eigenvalue computation and finding the root RRR. At the end of ?stegr2a, other processors might have a part of the spectrum that is needed to continue the computation locally. Once this eigenvalue information has been received by the processor, the computation can then proceed by calling the second part of the parallel MRRR algorithm, ?stegr2b.

Please note:

- The calling sequence has two additional integer parameters, (compared to LAPACK's [stegr](#)), these are *dol* and *dou* and should satisfy $m \geq dou \geq dol \geq 1$. These parameters are only relevant for the case *jobz* = 'V'.

Globally invoked over all processors, ?stegr2a computes all the eigenvalues specified by *range*.

?stegr2a locally only computes the eigenvalues corresponding to eigenvalues *dol* through *dou* in *w*, indexed *dol*-1 through *dou*-1. (That is, instead of computing the eigenvectors belonging to *w*[0] through *w*[*m*-1], only the eigenvectors belonging to eigenvalues *w*[*dol*-1] through *w*[*dou*-1] are computed. In this case, only the eigenvalues *dol* through *dou* are guaranteed to be fully accurate.

- *m* is not the number of eigenvalues specified by *range*, but it is $m = dou - dol + 1$. Instead, *m* refers to the number of eigenvalues computed on this processor.
- While no eigenvectors are computed in ?stegr2a itself (this is done later in ?stegr2b), the interface

If *jobz* = 'V' then, depending on *range* and *dol*, *dou*, ?stegr2a might need more workspace in *z* than the original ?stegr. In particular, the arrays *w* and *z* might not contain all the wanted eigenpairs locally, instead this information is distributed over other processors.

Notice revision #20110804

Input Parameters

<i>jobz</i>	= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.
<i>range</i>	= 'A': all eigenvalues will be found. = 'V': all eigenvalues in the half-open interval $(vl, vu]$ will be found. = 'I': eigenvalues of the entire matrix with the indices in a given range will be found.
<i>n</i>	The order of the matrix. $n \geq 0$.
<i>d</i>	Array of size n The n diagonal elements of the tridiagonal matrix T. Overwritten on exit.
<i>e</i>	Array of size n On entry, the $(n-1)$ subdiagonal elements of the tridiagonal matrix T in elements 0 to $n-2$ of e. $e[n-1]$ need not be set on input, but is used internally as workspace. Overwritten on exit.
<i>vl, vu</i>	If $range='V'$, the lower and upper bounds of the interval to be searched for eigenvalues. $vl < vu$. Not referenced if $range = 'A'$ or $'I'$.
<i>il, iu</i>	If $range='I'$, the indices (in ascending order) of the smallest eigenvalue, to be returned in $w[il-1]$, and largest eigenvalue, to be returned in $w[iu-1]$. $1 \leq il \leq iu \leq n$, if $n > 0$. Not referenced if $range = 'A'$ or $'V'$.
<i>ldz</i>	The leading dimension of the array z . $ldz \geq 1$, and if $jobz = 'V'$, then $ldz \geq \max(1, n)$.
<i>nzc</i>	The number of eigenvectors to be held in the array z. If $range = 'A'$, then $nzc \geq \max(1, n)$. If $range = 'V'$, then $nzc \geq$ the number of eigenvalues in $(vl, vu]$. If $range = 'I'$, then $nzc \geq iu - il + 1$. If $nzc = -1$, then a workspace query is assumed; the function calculates the number of columns of the matrix stored in array z that are needed to hold the eigenvectors. This value is returned as the first entry of the z array, and no error message related to nzc is issued.

<i>lwork</i>	The size of the array <i>work</i>. $lwork \geq \max(1, 18*n)$ if <i>jobz</i> = 'V', and $lwork \geq \max(1, 12*n)$ if <i>jobz</i> = 'N'. If <i>lwork</i> = -1, then a workspace query is assumed; the function only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued.
<i>liwork</i>	The size of the array <i>iwork</i>. $liwork \geq \max(1, 10*n)$ if the eigenvectors are desired, and $liwork \geq \max(1, 8*n)$ if only the eigenvalues are to be computed. If <i>liwork</i> = -1, then a workspace query is assumed; the function only calculates the optimal size of the <i>iwork</i> array, returns this value as the first entry of the <i>iwork</i> array, and no error message related to <i>liwork</i> is issued.
<i>dol, dou</i>	From all the eigenvalues $w[0]$ through $w[m-1]$, only eigenvalues $w[dol-1]$ through $w[dou-1]$ are computed.

OUTPUT Parameters

<i>m</i>	Globally summed over all processors, <i>m</i> equals the total number of eigenvalues found. $0 \leq m \leq n$. If <i>range</i> = 'A', $m = n$, and if <i>range</i> = 'I', $m = iu-il+1$. The local output equals $m = dou - dol + 1$.
<i>w</i>	Array of size <i>n</i> The first <i>m</i> elements contain approximations to the selected eigenvalues in ascending order. Note that immediately after exiting this function, only the eigenvalues indexed <i>dol</i>-1 through <i>dou</i>-1 are reliable on this processor because the eigenvalue computation is done in parallel. The other entries are very crude preliminary approximations. Other processors hold reliable information on these other parts of the <i>w</i> array. This information is communicated in the ScaLAPACK driver.
<i>z</i>	Array of size $ldz * \max(1, m)$. ?stegr2a does not compute eigenvectors, this is done in ?stegr2b. The argument <i>z</i> as well as all related other arguments only appear to keep the interface consistent and to signal to the user that this function is meant to be used when eigenvectors are computed.
<i>work</i>	On exit, if <i>info</i> = 0, <i>work</i>[0] returns the optimal (and minimal) <i>lwork</i>.
<i>iwork</i>	On exit, if <i>info</i> = 0, <i>iwork</i>[0] returns the optimal <i>liwork</i>.
<i>needil, neediu</i>	The indices of the leftmost and rightmost eigenvalues needed to accurately compute the relevant part of the representation tree. This information can be used to find out which processors have the relevant eigenvalue information needed so that it can be communicated.
<i>inderr</i>	<i>inderr</i> points to the place in the work space where the eigenvalue uncertainties (errors) are stored.

<i>nsplit</i>	The number of blocks into which <i>T</i> splits. $1 \leq nsplit \leq n$.
<i>pivmin</i>	The minimum pivot in the sturm sequence for <i>T</i> .
<i>scale</i>	The scaling factor for the tridiagonal <i>T</i> .
<i>wl, wu</i>	The interval (<i>wl</i> , <i>wu</i>] contains all the wanted eigenvalues. It is either given by the user or computed in ?larre2a .
<i>info</i>	On exit, <i>info</i> = 0: successful exit other: if <i>info</i> = - <i>i</i> , the <i>i</i> -th argument had an illegal value if <i>info</i> = 10 <i>x</i> , internal error in ?larre2a , Here, the digit <i>x</i> = $\text{abs}(iinfo) < 10$, where <i>iinfo</i> is the nonzero error code returned by ?larre2a .

Description

[?stegr2b](#) should only be called after a call to [?stegr2a](#). From eigenvalues and initial representations computed by [?stegr2a](#), [?stegr2b](#) computes the selected eigenvalues and eigenvectors of the real symmetric tridiagonal matrix in parallel on multiple processors. It is potentially invoked multiple times on a given processor because the locally relevant representation tree might depend on spectral information that is "owned" by other processors and might need to be communicated.

Please note:

- The calling sequence has two additional integer parameters, *dol* and *dou*, that should satisfy $m \geq dou \geq dol \geq 1$. These parameters are only relevant for the case *jobz* = 'V'. [?stegr2b](#) only computes the eigenvectors corresponding to eigenvalues *dol* through *dou* in *w*, indexed *dol*-1 through *dou*-1. (That is,

instead of computing the eigenvectors belonging to $w[0]$ through $w[m-1]$, only the eigenvectors belonging to eigenvalues $w[dol-1]$ through $w[dou-1]$ are computed. In this case, only the eigenvalues dol through dou are guaranteed to be accurately refined to all figures by Rayleigh-Quotient iteration.

- The additional arguments *vstart*, *finish*, *ndepth*, *parity*, *zoffset* are included as a thread-safe implementation equivalent to save variables. These variables store details about the local representation tree which is computed layerwise. For scalability reasons, eigenvalues belonging to the locally relevant representation tree might be computed on other processors. These need to be communicated before the inspection of the RRRs can proceed on any given layer. Note that only when the variable *finish* is non-zero, the computation has ended. All eigenpairs between *dol* and *dou* have been computed. *m* is set to $dou - dol + 1$.
- `?stegr2b` needs more workspace in *z* than the sequential `?stegr`. It is used to store the conformal embedding of the local representation tree.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

<i>jobz</i>	= 'N': Compute eigenvalues only; = 'V': Compute eigenvalues and eigenvectors.
<i>n</i>	The order of the matrix. $n \geq 0$.
<i>d</i>	Array of size <i>n</i> The <i>n</i> diagonal elements of the tridiagonal matrix T. Overwritten on exit.
<i>e</i>	Array of size <i>n</i> The (<i>n</i>-1) subdiagonal elements of the tridiagonal matrix T in elements 0 to <i>n</i>-2 of <i>e</i>. <i>e</i>[<i>n</i>-1] need not be set on input, but is used internally as workspace. Overwritten on exit.
<i>m</i>	The total number of eigenvalues found in <code>?stegr2a</code> . $0 \leq m \leq n$.
<i>w</i>	Array of size <i>n</i> The first <i>m</i> elements contain approximations to the selected eigenvalues in ascending order. Note that only the eigenvalues from the locally relevant part of the representation tree, that is all the clusters that include eigenvalues from <i>dol</i> through <i>dou</i>, are reliable on this processor. (It does not need to know about any others anyway.)
<i>ldz</i>	The leading dimension of the array <i>z</i> . $ldz \geq 1$, and if <i>jobz</i> = 'V', then $ldz \geq \max(1, n)$.

<i>nzc</i>	The number of eigenvectors to be held in the array <i>z</i> , storing the matrix <i>Z</i> .
<i>lwork</i>	The size of the array <i>work</i>. $lwork \geq \max(1, 18*n)$ if <i>jobz</i> = 'V', and $lwork \geq \max(1, 12*n)$ if <i>jobz</i> = 'N'. If <i>lwork</i> = -1, then a workspace query is assumed; the function only calculates the optimal size of the <i>work</i> array, returns this value as the first entry of the <i>work</i> array, and no error message related to <i>lwork</i> is issued.
<i>liwork</i>	The size of the array <i>iwork</i>. $liwork \geq \max(1, 10*n)$ if the eigenvectors are desired, and $liwork \geq \max(1, 8*n)$ if only the eigenvalues are to be computed. If <i>liwork</i> = -1, then a workspace query is assumed; the function only calculates the optimal size of the <i>iwork</i> array, returns this value as the first entry of the <i>iwork</i> array, and no error message related to <i>liwork</i> is issued.
<i>dol, dou</i>	From the eigenvalues $w[0]$ through $w[m-1]$, only eigenvectors $Z(:, dol)$ to $Z(:, dou)$ are computed. If <i>dol</i> > 1, then $Z(:, dol-1-zoffset)$ is used and overwritten. If <i>dou</i> < <i>m</i>, then $Z(:, dou+1-zoffset)$ is used and overwritten.
<i>needil, neediu</i>	Describes which are the left and right outermost eigenvalues still to be computed. Initially computed by ?larre2a , modified in the course of the algorithm.
<i>pivmin</i>	The minimum pivot in the sturm sequence for <i>T</i> .
<i>scale</i>	The scaling factor for <i>T</i> . Used for unscaling the eigenvalues at the very end of the algorithm.
<i>wl, wu</i>	The interval (<i>wl</i> , <i>wu</i>] contains all the wanted eigenvalues.
<i>vstart</i>	Non-zero on initialization, set to zero afterwards.
<i>finish</i>	Indicates whether all eigenpairs have been computed.
<i>maxcls</i>	The largest cluster worked on by this processor in the representation tree.
<i>ndepth</i>	The current depth of the representation tree. Set to zero on initial pass, changed when the deeper levels of the representation tree are generated.
<i>parity</i>	An internal parameter needed for the storage of the clusters on the current level of the representation tree.
<i>zoffset</i>	Offset for storing the eigenpairs when <i>z</i> is distributed in 1D-cyclic fashion.

OUTPUT Parameters

<i>z</i>	Array of size $ldz * \max(1, m)$

If *jobz* = 'V', and if *info* = 0, then a subset of the first *m* columns of the matrix *Z*, stored in *z*, contain the orthonormal eigenvectors of the matrix *T* corresponding to the selected eigenvalues, with the *i*-th column of *Z* holding the eigenvector associated with *w*[*i*-1].

See *dol*, *dou* for more information.

<i>isuppz</i>	array of size $2 \cdot \max(1, m)$. The support of the eigenvectors in <i>z</i> , i.e., the indices indicating the nonzero elements in <i>z</i> . The <i>i</i> -th computed eigenvector is nonzero only in elements <i>isuppz</i> [$2 \cdot i - 2$] through <i>isuppz</i> [$2 \cdot i - 1$]. This is relevant in the case when the matrix is split. <i>isuppz</i> is only set if <i>n</i> > 2.
<i>work</i>	On exit, if <i>info</i> = 0, <i>work</i> [0] returns the optimal (and minimal) <i>lwork</i> .
<i>iwork</i>	On exit, if <i>info</i> = 0, <i>iwork</i> [0] returns the optimal <i>liwork</i> .
<i>needil</i> , <i>neediu</i>	Modified in the course of the algorithm.
<i>indwlc</i>	Pointer into the workspace location where the local eigenvalue representations are stored. ("Local eigenvalues" are those relative to the individual shifts of the RRRs.)
<i>vstart</i>	Non-zero on initialization, set to zero afterwards.
<i>finish</i>	Indicates whether all eigenpairs have been computed
<i>maxcls</i>	The largest cluster worked on by this processor in the representation tree.
<i>ndepth</i>	The current depth of the representation tree. Set to zero on initial pass, changed when the deeper levels of the representation tree are generated.
<i>parity</i>	An internal parameter needed for the storage of the clusters on the current level of the representation tree.
<i>info</i>	On exit, <i>info</i> = 0: successful exit other: if <i>info</i> = - <i>i</i> , the <i>i</i> -th argument had an illegal value if <i>info</i> = 20 <i>x</i> , internal error in ?larrv2 . Here, the digit <i>x</i> = $\text{abs}(\text{iinfo}) < 10$, where <i>iinfo</i> is the nonzero error code returned by ?larrv2

?stein2

Computes the eigenvectors corresponding to specified eigenvalues of a real symmetric tridiagonal matrix, using inverse iteration.

Syntax

```
void sstein2 (MKL_INT *n , float *d , float *e , MKL_INT *m , float *w , MKL_INT
*iblock , MKL_INT *isplit , float *orfac , float *z , MKL_INT *ldz , float *work ,
MKL_INT *iwork , MKL_INT *ifail , MKL_INT *info );

void dstein2 (MKL_INT *n , double *d , double *e , MKL_INT *m , double *w , MKL_INT
*iblock , MKL_INT *isplit , double *orfac , double *z , MKL_INT *ldz , double *work ,
MKL_INT *iwork , MKL_INT *ifail , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The `?stein2` function is a modified LAPACK function `?stein`. It computes the eigenvectors of a real symmetric tridiagonal matrix T corresponding to specified eigenvalues, using inverse iteration.

The maximum number of iterations allowed for each eigenvector is specified by an internal parameter *maxits* (currently set to 5).

Input Parameters

n	The order of the matrix T ($n \geq 0$).
m	The number of eigenvectors to be found ($0 \leq m \leq n$).
d, e, w	Arrays: d, of size n. The n diagonal elements of the tridiagonal matrix T. e, of size n. The $(n-1)$ subdiagonal elements of the tridiagonal matrix T, in elements 1 to $n-1$. $e[n-1]$ need not be set. w, of size n. The first m elements of w contain the eigenvalues for which eigenvectors are to be computed. The eigenvalues should be grouped by split-off block and ordered from smallest to largest within the block. (The output array w from <code>?stebz</code> with <code>ORDER = 'B'</code> is expected here). The size of w must be at least $\max(1, n)$.
$iblock$	Array of size n. The submatrix indices associated with the corresponding eigenvalues in w; $iblock[i] = 1$, if eigenvalue $w[i]$ belongs to the first submatrix from the top, $iblock[i] = 2$, if eigenvalue $w[i]$ belongs to the second submatrix, etc. (The output array $iblock$ from <code>?stebz</code> is expected here).
$isplit$	Array of size n .

The splitting points, at which T breaks up into submatrices. The first submatrix consists of rows/columns 1 to `isplit[0]`, the second submatrix consists of rows/columns `isplit[0]+1` through `isplit[1]`, etc. (The output array `isplit` from `?stebz` is expected here).

`orfac` `orfac` specifies which eigenvectors should be orthogonalized. Eigenvectors that correspond to eigenvalues which are within $orfac * ||T||$ of each other are to be orthogonalized.

`ldz` The leading dimension of the output array `z`; $ldz \geq \max(1, n)$.

`work` Workspace array of size $5n$.

`iwork` Workspace array of size n .

Output Parameters

`z` Array of size $ldz * m$.

The computed eigenvectors. The eigenvector associated with the eigenvalue $w[i]$ is stored in the $(i+1)$ -th column of the matrix Z represented by `z`, $i=0, \dots, m-1$. Any vector that fails to converge is set to its current iterate after `maxits` iterations.

`ifail` Array of size m .

On normal exit, all elements of `ifail` are zero. If one or more eigenvectors fail to converge after `maxits` iterations, then their indices are stored in the array `ifail`.

`info`

`info = 0`, the exit is successful.

`info < 0`: if `info = -i`, the i -th had an illegal value.

`info > 0`: if `info = i`, then i eigenvectors failed to converge in `maxits` iterations. Their indices are stored in the array `ifail`.

See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

?dbtf2

Computes an LU factorization of a general band matrix with no pivoting (local unblocked algorithm).

Syntax

```
void sdbtf2 (MKL_INT *m , MKL_INT *n , MKL_INT *kl , MKL_INT *ku , float *ab , MKL_INT
*ldab , MKL_INT *info );

void ddbtf2 (MKL_INT *m , MKL_INT *n , MKL_INT *kl , MKL_INT *ku , double *ab ,
MKL_INT *ldab , MKL_INT *info );

void cdbtf2 (MKL_INT *m , MKL_INT *n , MKL_INT *kl , MKL_INT *ku , MKL_Complex8 *ab ,
MKL_INT *ldab , MKL_INT *info );

void zdbtf2 (MKL_INT *m , MKL_INT *n , MKL_INT *kl , MKL_INT *ku , MKL_Complex16 *ab ,
MKL_INT *ldab , MKL_INT *info );
```

The function does not use array elements marked `*`; elements marked `+` need not be set on entry, but the function requires them to store elements of U , because of fill-in resulting from the row interchanges.

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

?dbtrf

Computes an LU factorization of a general band matrix with no pivoting (local blocked algorithm).

Syntax

```
void sdbtrf (MKL_INT *m , MKL_INT *n , MKL_INT *kl , MKL_INT *ku , float *ab , MKL_INT
*ldab , MKL_INT *info );

void ddbtrf (MKL_INT *m , MKL_INT *n , MKL_INT *kl , MKL_INT *ku , double *ab ,
MKL_INT *ldab , MKL_INT *info );

void cdbtrf (MKL_INT *m , MKL_INT *n , MKL_INT *kl , MKL_INT *ku , MKL_Complex8 *ab ,
MKL_INT *ldab , MKL_INT *info );

void zdbtrf (MKL_INT *m , MKL_INT *n , MKL_INT *kl , MKL_INT *ku , MKL_Complex16 *ab ,
MKL_INT *ldab , MKL_INT *info );
```

Include Files

- `mk1_scalapack.h`

Description

This function computes an LU factorization of a real m -by- n band matrix A without using partial pivoting or row interchanges.

This is the blocked version of the algorithm, calling [BLAS Routines and Functions](#).

Input Parameters

m	The number of rows of the matrix A ($m \geq 0$).
n	The number of columns in A ($n \geq 0$).
kl	The number of sub-diagonals within the band of A ($kl \geq 0$).
ku	The number of super-diagonals within the band of A ($ku \geq 0$).
ab	Array of size $ldab * n$. The matrix A in band storage, in rows $kl+1$ to $2kl+ku+1$; rows 1 to kl need not be set. The j -th column of A is stored in the array ab as follows: $ab[kl + ku + i - j + (j-1) * ldab] = A(i, j)$ for $\max(1, j - ku) \leq i \leq \min(m, j + kl)$.
$ldab$	The leading dimension of the array ab . ($ldab \geq 2kl + ku + 1$)

Output Parameters

<i>ab</i>	On exit, details of the factorization: U is stored as an upper triangular band matrix with $kl+ku$ superdiagonals in rows 1 to $kl+ku+1$, and the multipliers used during the factorization are stored in rows $kl+ku+2$ to $2*kl+ku+1$. See the <i>Application Notes</i> below for further details.
<i>info</i>	= 0: successful exit < 0: if <i>info</i> = - <i>i</i>, the <i>i</i>-th argument had an illegal value, > 0: if <i>info</i> = + <i>i</i>, the matrix element $U(i,i)$ is 0. The factorization has been completed, but the factor U is exactly singular. Division by 0 will occur if you use the factor U for solving a system of linear equations.

Application Notes

The band storage scheme is illustrated by the following example, when $m = n = 6$, $kl = 2$, $ku = 1$:

The function does not use array elements marked *.

?dtttrf

Computes an LU factorization of a general tridiagonal matrix with no pivoting (local blocked algorithm).

Syntax

```
void sdtttrf (MKL_INT *n , float *dl , float *d , float *du , MKL_INT *info );
void ddtttrf (MKL_INT *n , double *dl , double *d , double *du , MKL_INT *info );
void cdtttrf (MKL_INT *n , MKL_Complex8 *dl , MKL_Complex8 *d , MKL_Complex8 *du ,
MKL_INT *info );
void zdtttrf (MKL_INT *n , MKL_Complex16 *dl , MKL_Complex16 *d , MKL_Complex16 *du ,
MKL_INT *info );
```

Include Files

- `mkl_scalapack.h`

Description

The `?dtttrf` function computes an LU factorization of a real or complex tridiagonal matrix A using elimination without partial pivoting.

The factorization has the form $A = L*U$, where L is a product of unit lower bidiagonal matrices and U is upper triangular with nonzeros only in the main diagonal and first superdiagonal.

Input Parameters

n	The order of the matrix A ($n \geq 0$).
dl, d, du	Arrays containing elements of A . The array dl of size $(n-1)$ contains the sub-diagonal elements of A . The array d of size n contains the diagonal elements of A . The array du of size $(n-1)$ contains the super-diagonal elements of A .

Output Parameters

dl	Overwritten by the $(n-1)$ multipliers that define the matrix L from the LU factorization of A .
d	Overwritten by the n diagonal elements of the upper triangular matrix U from the LU factorization of A .
du	Overwritten by the $(n-1)$ elements of the first super-diagonal of U .
$info$	= 0: successful exit < 0: if $info = -i$, the i -th argument had an illegal value, > 0: if $info = i$, the matrix element $U(i,i)$ is exactly 0. The factorization has been completed, but the factor U is exactly singular. Division by 0 will occur if you use the factor U for solving a system of linear equations.

See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

?dtttrsv

Solves a general tridiagonal system of linear equations using the LU factorization computed by ?dttrf.

Syntax

```
void sdttrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *nrhs , float *dl ,
float *d , float *du , float *b , MKL_INT *ldb , MKL_INT *info );

void ddttrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *nrhs , double *dl ,
double *d , double *du , double *b , MKL_INT *ldb , MKL_INT *info );

void cdttrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *nrhs , MKL_Complex8
*d , MKL_Complex8 *d , MKL_Complex8 *du , MKL_Complex8 *b , MKL_INT *ldb , MKL_INT
*info );

void zdttrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *nrhs , MKL_Complex16
*d , MKL_Complex16 *d , MKL_Complex16 *du , MKL_Complex16 *b , MKL_INT *ldb , MKL_INT
*info );
```

Include Files

- mkl_scalapack.h

Description

The ?dtttrsv function solves one of the following systems of linear equations:

$L^*X = B$, $L^T * X = B$, or $L^H * X = B$,

$U^*X = B$, $U^T * X = B$, or $U^H * X = B$

with factors of the tridiagonal matrix A from the LU factorization computed by [?dtttrf](#).

Input Parameters

<i>uplo</i>	Specifies whether to solve with L or U .
<i>trans</i>	Must be 'N' or 'T' or 'C'. Indicates the form of the equations: If <i>trans</i> = 'N', then $A^*X=B$ is solved for X (no transpose). If <i>trans</i> = 'T', then $A^T * X = B$ is solved for X (transpose). If <i>trans</i> = 'C', then $A^H * X = B$ is solved for X (conjugate transpose).
<i>n</i>	The order of the matrix A ($n \geq 0$).
<i>nrhs</i>	The number of right-hand sides, that is, the number of columns in the matrix B ($nrhs \geq 0$).
<i>dl,d,du,b</i>	The array <i>dl</i> of size $(n - 1)$ contains the $(n - 1)$ multipliers that define the matrix L from the LU factorization of A . The array <i>d</i> of size n contains n diagonal elements of the upper triangular matrix U from the LU factorization of A . The array <i>du</i> of size $(n - 1)$ contains the $(n - 1)$ elements of the first super-diagonal of U . On entry, the array <i>b</i> of size $ldb * nrhs$ contains the right-hand side of matrix B .
<i>ldb</i>	The leading dimension of the array <i>b</i> ; $ldb \geq \max(1, n)$.

Output Parameters

<i>b</i>	Overwritten by the solution matrix X .
<i>info</i>	If <i>info</i> =0, the execution is successful. If <i>info</i> = $-i$, the i -th parameter had an illegal value.

See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

?pttrsv

Solves a symmetric (Hermitian) positive-definite tridiagonal system of linear equations, using the $L^*D^*L^H$ factorization computed by [?pttrf](#).

Syntax

```
void spttrsv (char *trans , MKL_INT *n , MKL_INT *nrhs , float *d , float *e , float
*b , MKL_INT *ldb , MKL_INT *info );

void dpttrsv (char *trans , MKL_INT *n , MKL_INT *nrhs , double *d , double *e ,
double *b , MKL_INT *ldb , MKL_INT *info );
```

```
void cpttrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *nrhs , float *d ,
MKL_Complex8 *e , MKL_Complex8 *b , MKL_INT *ldb , MKL_INT *info );

void zpttrsv (char *uplo , char *trans , MKL_INT *n , MKL_INT *nrhs , double *d ,
MKL_Complex16 *e , MKL_Complex16 *b , MKL_INT *ldb , MKL_INT *info );
```

Include Files

- mkl_scalapack.h

Description

The `?pttrsv` function solves one of the triangular systems:

$L^T * X = B$, or $L * X = B$ for real flavors,

or

$L * X = B$, or $L^H * X = B$,

$U * X = B$, or $U^H * X = B$ for complex flavors,

where L (or U for complex flavors) is the Cholesky factor of a Hermitian positive-definite tridiagonal matrix A such that

$A = L * D * L^H$ (computed by `spttrf/dpttrf`)

or

$A = U^H * D * U$ or $A = L * D * L^H$ (computed by `cpttrf/zpttrf`).

Input Parameters

<i>uplo</i>	Must be 'U' or 'L'. Specifies whether the superdiagonal or the subdiagonal of the tridiagonal matrix A is stored and the form of the factorization: If <i>uplo</i> = 'U', e is the superdiagonal of U, and $A = U^H * D * U$ or $A = L * D * L^H$; if <i>uplo</i> = 'L', e is the subdiagonal of L, and $A = L * D * L^H$. The two forms are equivalent, if A is real.
<i>trans</i>	Specifies the form of the system of equations: for real flavors: if <i>trans</i> = 'N': $L * X = B$ (no transpose) if <i>trans</i> = 'T': $L^T * X = B$ (transpose) for complex flavors: if <i>trans</i> = 'N': $U * X = B$ or $L * X = B$ (no transpose) if <i>trans</i> = 'C': $U^H * X = B$ or $L^H * X = B$ (conjugate transpose).
<i>n</i>	The order of the tridiagonal matrix A . $n \geq 0$.
<i>nrhs</i>	The number of right hand sides, that is, the number of columns of the matrix B . $nrhs \geq 0$.
<i>d</i>	array of size n . The n diagonal elements of the diagonal matrix D from the factorization computed by <code>?pttrf</code> .

<i>e</i>	array of size $(n-1)$. The $(n-1)$ off-diagonal elements of the unit bidiagonal factor U or L from the factorization computed by ?pttrf . See <i>uplo</i> .
<i>b</i>	array of size $ldb * nrhs$. On entry, the right hand side matrix B .
<i>ldb</i>	The leading dimension of the array b . $ldb \geq \max(1, n)$.

Output Parameters

<i>b</i>	On exit, the solution matrix X .
<i>info</i>	= 0: successful exit < 0: if <i>info</i> = $-i$, the i -th argument had an illegal value.

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

?steqr2

Computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method.

Syntax

```
void ssteqr2 (char *compz , MKL_INT *n , float *d , float *e , float *z , MKL_INT
*ldz , MKL_INT *nr , float *work , MKL_INT *info );

void dsteqr2 (char *compz , MKL_INT *n , double *d , double *e , double *z , MKL_INT
*ldz , MKL_INT *nr , double *work , MKL_INT *info );
```

Include Files

- `mkl_scalapack.h`

Description

The [?steqr2](#) function is a modified version of LAPACK function [?steqr](#). The [?steqr2](#) function computes all eigenvalues and, optionally, eigenvectors of a symmetric tridiagonal matrix using the implicit QL or QR method. [?steqr2](#) is modified from [?steqr](#) to allow each ScaLAPACK process running [?steqr2](#) to perform updates on a distributed matrix Q . Proper usage of [?steqr2](#) can be gleaned from examination of ScaLAPACK function [p?syev](#).

Input Parameters

<i>compz</i>	Must be 'N' or 'I'. If <i>compz</i> = 'N', the function computes eigenvalues only. If <i>compz</i> = 'I', the function computes the eigenvalues and eigenvectors of the tridiagonal matrix T . <i>z</i> must be initialized to the identity matrix by p?laset or ?laset prior to entering this function.

n	The order of the matrix T ($n \geq 0$).
$d, e, work$	Arrays: d contains the diagonal elements of T. The size of d must be at least $\max(1, n)$. e contains the $(n-1)$ subdiagonal elements of T. The size of e must be at least $\max(1, n-1)$. $work$ is a workspace array. The size of $work$ is $\max(1, 2*n-2)$. If $compz = 'N'$, then $work$ is not referenced.
z	(local) Array of global size $n * n$ and of local size $ldz * nr$. If $compz = 'V'$, then z contains the orthogonal matrix used in the reduction to tridiagonal form.
ldz	The leading dimension of the array z. Constraints: $ldz \geq 1$, $ldz \geq \max(1, n)$, if eigenvectors are desired.
nr	$nr = \max(1, \text{numroc}(n, nb, myprow, 0, nprocs))$. If $compz = 'N'$, then nr is not referenced.

Output Parameters

d	On exit, the eigenvalues in ascending order, if $info = 0$. See also $info$.
e	On exit, e has been destroyed.
z	On exit, if $info = 0$, then, if $compz = 'V'$, z contains the orthonormal eigenvectors of the original symmetric matrix, and if $compz = 'I'$, z contains the orthonormal eigenvectors of the symmetric tridiagonal matrix. If $compz = 'N'$, then z is not referenced.
$info$	$info = 0$, the exit is successful. $info < 0$: if $info = -i$, the i-th had an illegal value. $info > 0$: the algorithm has failed to find all the eigenvalues in a total of $30n$ iterations; if $info = i$, then i elements of e have not converged to zero; on exit, d and e contain the elements of a symmetric tridiagonal matrix, which is orthogonally similar to the original matrix.

Utility Functions and Routines

This section describes ScaLAPACK utility functions and routines. Summary information about these routines is given in the following table:

ScaLAPACK Utility Functions and Routines

Routine Name	Data Types	Description
p?labad	s,d	Returns the square root of the underflow and overflow thresholds if the exponent-range is very large.
p?latchieee	s,d	Performs a simple check for the features of the IEEE standard.
p?lamch	s,d	Determines machine parameters for floating-point arithmetic.
p?lasnbt	s,d	Computes the position of the sign bit of a floating-point number.

See Also

[pxerbla](#) Error handling routine called by ScaLAPACK routines.

p?labad

Returns the square root of the underflow and overflow thresholds if the exponent-range is very large.

Syntax

```
void pslabad (MKL_INT *ictxt , float *small , float *large );
void pdlabad (MKL_INT *ictxt , double *small , double *large );
```

Include Files

- `mkl_scalapack.h`

Description

The `p?labad` function takes as input the values computed by [p?lamch](#) for underflow and overflow, and returns the square root of each of these values if the log of *large* is sufficiently large. This function is intended to identify machines with a large exponent range, such as the Crays, and redefine the underflow and overflow limits to be the square roots of the values computed by `p?lamch`. This function is needed because `p?lamch` does not compensate for poor arithmetic in the upper half of the exponent range, as is found on a Cray.

In addition, this function performs a global minimization and maximization on these values, to support heterogeneous computing networks.

Input Parameters

<i>ictxt</i>	(global) The BLACS context handle in which the computation takes place.
<i>small</i>	(local). On entry, the underflow threshold as computed by <code>p?lamch</code> .
<i>large</i>	(local). On entry, the overflow threshold as computed by <code>p?lamch</code> .

Output Parameters

<i>small</i>	(local). On exit, if $\log_{10}(\textit{large})$ is sufficiently large, the square root of <i>small</i> , otherwise unchanged.
<i>large</i>	(local). On exit, if $\log_{10}(\textit{large})$ is sufficiently large, the square root of <i>large</i> , otherwise unchanged.

See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

p?latchieee

Performs a simple check for the features of the IEEE standard.

Syntax

```
void pslatchieee (MKL_INT *isieee , float *rmax , float *rmin );
void pdlatchieee (MKL_INT *isieee , float *rmax , float *rmin );
```

Include Files

- `mkl_scalapack.h`

Description

The `p?latchieee` function performs a simple check to make sure that the features of the IEEE standard are implemented. In some implementations, `p?latchieee` may not return.

This is a ScaLAPACK internal function and arguments are not checked for unreasonable values.

Input Parameters

<i>rmax</i>	(local). The overflow threshold (= <code>?lamch ('O')</code>).
<i>rmin</i>	(local). The underflow threshold (= <code>?lamch ('U')</code>).

Output Parameters

<i>isieee</i>	(local). On exit, <i>isieee</i> = 1 implies that all the features of the IEEE standard that we rely on are implemented. On exit, <i>isieee</i> = 0 implies that some the features of the IEEE standard that we rely on are missing.

See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

p?lamch

Determines machine parameters for floating-point arithmetic.

Syntax

```
float pslamch (MKL_INT *ictxt , char *cmach );
double pdlamch (MKL_INT *ictxt , char *cmach );
```

Include Files

- mkl_scalapack.h

Description

The p?lamch function determines single precision machine parameters.

Input Parameters

ictxt (global). The BLACS context handle in which the computation takes place.

cmach (global)
Specifies the value to be returned by p?lamch:

= 'E' or 'e', p?lamch := eps
= 'S' or 's', p?lamch := sfmin
= 'B' or 'b', p?lamch := base
= 'P' or 'p', p?lamch := eps*base
= 'N' or 'n', p?lamch := t
= 'R' or 'r', p?lamch := rnd
= 'M' or 'm', p?lamch := emin
= 'U' or 'u', p?lamch := rmin
= 'L' or 'l', p?lamch := emax
= 'O' or 'o', p?lamch := rmax,

where

eps = relative machine precision

sfmin = safe minimum, such that 1/sfmin does not overflow

base = base of the machine

prec = eps*base

t = number of (base) digits in the mantissa

rnd = 1.0 when rounding occurs in addition, 0.0 otherwise

emin = minimum exponent before (gradual) underflow

rmin = underflow threshold - $\text{base}^{(\text{emin}-1)}$

emax = largest exponent before overflow

rmax = overflow threshold - $(\text{base}^{\text{emax}}) * (1-\text{eps})$

Output Parameters

val Value returned by the function.

See Also

[Overview](#) for details of ScaLAPACK array descriptor structures and related notations.

p?lasnbt

Computes the position of the sign bit of a floating-point number.

Syntax

```
void pslasnb (MKL_INT *ieflag );
void pdlasnb (MKL_INT *ieflag );
```

Include Files

- `mkl_scalapack.h`

Description

The `p?lasnbt` function finds the position of the signbit of a single/double precision floating point number. This function assumes IEEE arithmetic, and hence, tests only the 32-nd bit (for single precision) or 32-nd and 64-th bits (for double precision) as a possibility for the signbit. `sizeof(int)` is assumed equal to 4 bytes.

If a compile time flag (`NO_IEEE`) indicates that the machine does not have IEEE arithmetic, `ieflag = 0` is returned.

Output Parameters

ieflag This flag indicates the position of the signbit of any single/double precision floating point number.

ieflag = 0, if the compile time flag `NO_IEEE` indicates that the machine does not have IEEE arithmetic, or if `sizeof(int)` is different from 4 bytes.

ieflag = 1 indicates that the signbit is the 32-nd bit for a single precision function.

In the case of a double precision function:

ieflag = 1 indicates that the signbit is the 32-nd bit (Big Endian).

ieflag = 2 indicates that the signbit is the 64-th bit (Little Endian).

Matrix Redistribution/Copy Routines

This section describes ScaLAPACK redistribution/copy routines. Summary information about these routines is given in the following table:

ScaLAPACK Redistribution/Copy Routines

Routine Name	Data Types	Description
<code>p?gemr2d</code>	<code>s, d, c, z, i</code>	Copies a submatrix from one general rectangular matrix to another.

Routine Name	Data Types	Description
p?trmr2d	s,d,c,z,i	Copies a submatrix from one trapezoidal matrix to another.

See Also

[pxerbla](#) Error handling routine called by ScaLAPACK routines.

p?gemr2d

Copies a submatrix from one general rectangular matrix to another.

Syntax

```
void psgemr2d (MKL_INT *m, MKL_INT *n, float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , float *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb , MKL_INT *ictxt );

void pdgemr2d (MKL_INT *m , MKL_INT *n , double *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , double *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb , MKL_INT
*ictxt );

void pcgemr2d (MKL_INT *m , MKL_INT *n MKL_Complex8 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_Complex8 *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb ,
MKL_INT *ictxt );

void pzgemr2d (MKL_INT *m , MKL_INT *n , MKL_Complex16 *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca , MKL_Complex16 *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb ,
MKL_INT *ictxt );

void pigemr2d (MKL_INT *m , MKL_INT *n , int *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca , int *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb , MKL_INT *ictxt );
```

Include Files

- `mkl_scalapack.h`

Description

The `p?gemr2d` function copies the indicated matrix or submatrix of A to the indicated matrix or submatrix of B . It provides a truly general copy from any block cyclicly-distributed matrix or submatrix to any other block cyclicly-distributed matrix or submatrix. With [p?trmr2d](#), these functions are the only ones in the ScaLAPACK library which provide inter-context operations: they can take a matrix or submatrix A in context A (distributed over process grid A) and copy it to a matrix or submatrix B in context B (distributed over process grid B).

There does not need to be a relationship between the two operand matrices or submatrices other than their global size and the fact that they are both legal block cyclicly-distributed matrices or submatrices. This means that they can, for example, be distributed across different process grids, have varying block sizes and differing matrix starting points, or be contained in different sized distributed matrices.

Take care when context A is disjoint from context B . The general rules for which parameters need to be set are:

- All calling processes must have the correct m and n .
- Processes in context A must correctly define all parameters describing A .
- Processes in context B must correctly define all parameters describing B .
- Processes which are not members of context A must pass `ctxt_a = -1` and need not set other parameters describing A .
- Processes which are not members of context B must pass `ctxt_b = -1` and need not set other parameters describing B .

Because of its generality, `p?gemr2d` can be used for many operations not usually associated with copy functions. For instance, it can be used to take a matrix on one process and distribute it across a process grid, or the reverse. If a supercomputer is grouped into a virtual parallel machine with a workstation, for instance, this function can be used to move the matrix from the workstation to the supercomputer and back. In ScaLAPACK, it is called to copy matrices from a two-dimensional process grid to a one-dimensional process grid. It can be used to redistribute matrices so that distributions providing maximal performance can be used by various component libraries, as well.

Note that this function requires an array descriptor with `dtype_ = 1`.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

<i>m</i>	(global) The number of rows of matrix <i>A</i> to be copied ($m \geq 0$).
<i>n</i>	(global) The number of columns of matrix <i>A</i> to be copied ($n \geq 0$).
<i>nrhs</i>	(global) The number of right hand sides; the number of columns of the distributed submatrix <code>sub(B)</code> ($nrhs \geq 0$).
<i>a</i>	(local) Pointer into the local memory to array of size <code>lld_a * LOCC(ja+n-1)</code> containing the source matrix <i>A</i> .
<i>ia, ja</i>	(global) The row and column indices in the array <i>A</i> indicating the first row and the first column, respectively, of the submatrix of <i>A</i> to copy. $1 \leq ia \leq total\_rows\_in\_a - m + 1$, $1 \leq ja \leq total\_columns\_in\_a - n + 1$.
<i>desca</i>	(global and local) array of size <code>dlen_</code> . The array descriptor for the distributed matrix <i>A</i> . Only <code>dtype_a = 1</code> is supported, so <code>dlen_ = 9</code> . If the calling process is not part of the context of <i>A</i> , <code>ctxt_a</code> must be equal to -1.
<i>ib, jb</i>	(global) The row and column indices in the array <i>B</i> indicating the first row and the first column, respectively, of the submatrix <i>B</i> to which to copy the matrix. $1 \leq ib \leq total\_rows\_in\_b - m + 1$, $1 \leq jb \leq total\_columns\_in\_b - n + 1$.
<i>descb</i>	(global and local) array of size <code>dlen_</code> . The array descriptor for the distributed matrix <i>B</i> . Only <code>dtype_b = 1</code> is supported, so <code>dlen_ = 9</code> . If the calling process is not part of the context of <i>B</i> , <code>ctxt_b</code> must be equal to -1.

ictxt (global).

The context encompassing at least the union of all processes in context *A* and context *B*. All processes in the context *ictxt* must call this function, even if they do not own a piece of either matrix.

Output Parameters

b Pointer into the local memory to array of size $lld\_b * LOCC(jb + nrhs - 1)$.
Overwritten by the submatrix from *A*.

*descb , MKL_INT *ictxt );
```

Include Files

- mkl_scalapack.h

Description

The `p?trmr2d` function copies the indicated matrix or submatrix of *A* to the indicated matrix or submatrix of *B*. It provides a truly general copy from any block cyclicly-distributed matrix or submatrix to any other block cyclicly-distributed matrix or submatrix. With `p?gemr2d`, these functions are the only ones in the ScaLAPACK library which provide inter-context operations: they can take a matrix or submatrix *A* in context *A* (distributed over process grid *A*) and copy it to a matrix or submatrix *B* in context *B* (distributed over process grid *B*).

The `p?trmr2d` function assumes the matrix or submatrix to be trapezoidal. Only the upper or lower part is copied, and the other part is unchanged.

There does not need to be a relationship between the two operand matrices or submatrices other than their global size and the fact that they are both legal block cyclicly-distributed matrices or submatrices. This means that they can, for example, be distributed across different process grids, have varying block sizes and differing matrix starting points, or be contained in different sized distributed matrices.

Take care when context *A* is disjoint from context *B*. The general rules for which parameters need to be set are:

- All calling processes must have the correct *m* and *n*.
- Processes in context *A* must correctly define all parameters describing *A*.
- Processes in context *B* must correctly define all parameters describing *B*.
- Processes which are not members of context *A* must pass *ctxt_a* = -1 and need not set other parameters describing *A*.
- Processes which are not members of context *B* must pass *ctxt_b* = -1 and need not set other parameters describing *B*.

Because of its generality, `p?trmr2d` can be used for many operations not usually associated with copy functions. For instance, it can be used to take a matrix on one process and distribute it across a process grid, or the reverse. If a supercomputer is grouped into a virtual parallel machine with a workstation, for instance, this function can be used to move the matrix from the workstation to the supercomputer and back. In ScaLAPACK, it is called to copy matrices from a two-dimensional process grid to a one-dimensional process grid. It can be used to redistribute matrices so that distributions providing maximal performance can be used by various component libraries, as well.

Note that this function requires an array descriptor with *dtype_* = 1.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

<i>uplo</i>	(global) Specifies whether to copy the upper or lower part of the matrix or submatrix.
<i>uplo</i> = 'U'	Copy the upper triangular part.
<i>uplo</i> = 'L'	Copy the lower triangular part.
<i>diag</i>	(global) Specifies whether to copy the diagonal of the matrix or submatrix.
<i>diag</i> = 'U'	Do not copy the diagonal.
<i>diag</i> = 'N'	Copy the diagonal.
<i>m</i>	(global) The number of rows of matrix <i>A</i> to be copied ($m \geq 0$).
<i>n</i>	(global) The number of columns of matrix <i>A</i> to be copied ($n \geq 0$).

<i>a</i>	(local) Pointer into the local memory to array of size $lld\_a * LOCC(ja+n-1)$ containing the source matrix <i>A</i> .
<i>ia, ja</i>	(global) The row and column indices in the array <i>A</i> indicating the first row and the first column, respectively, of the submatrix of <i>A</i> to copy. $1 \leq ia \leq total\_rows\_in\_a - m + 1, 1 \leq ja \leq total\_columns\_in\_a - n + 1$.
<i>desca</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>A</i> . Only <i>dtype_a</i> = 1 is supported, so <i>dlen_</i> = 9. If the calling process is not part of the context of <i>A</i> , <i>ctxt_a</i> must be equal to -1.
<i>ib, jb</i>	(global) The row and column indices in the array <i>B</i> indicating the first row and the first column, respectively, of the submatrix <i>B</i> to which to copy the matrix. $1 \leq ib \leq total\_rows\_in\_b - m + 1, 1 \leq jb \leq total\_columns\_in\_b - n + 1$.
<i>descb</i>	(global and local) array of size <i>dlen_</i> . The array descriptor for the distributed matrix <i>B</i> . Only <i>dtype_b</i> = 1 is supported, so <i>dlen_</i> = 9. If the calling process is not part of the context of <i>B</i> , <i>ctxt_b</i> must be equal to -1.
<i>ictxt</i>	(global). The context encompassing at least the union of all processes in context <i>A</i> and context <i>B</i> . All processes in the context <i>ictxt</i> must call this function, even if they do not own a piece of either matrix.

Output Parameters

<i>b</i>	Pointer into the local memory to array of size $lld\_b * LOCC(jb+nrhs-1)$. Overwritten by the submatrix from <i>A</i> .

Sparse Solver Routines

Intel® Math Kernel Library (Intel® MKL) provides user-callable sparse solver software to solve real or complex, symmetric, structurally symmetric or nonsymmetric, positive definite, indefinite or Hermitian square sparse linear system of algebraic equations.

The terms and concepts required to understand the use of the Intel MKL sparse solver routines are discussed in the [Appendix A "Linear Solvers Basics"](#). If you are familiar with linear sparse solvers and sparse matrix storage schemes, you can skip these sections and go directly to the interface descriptions.

This chapter describes

- the direct sparse solver based on PARDISO* which is referred to here as [Intel MKL PARDISO](#);
- the alternative interface for the direct sparse solver which is referred to here as the [DSS interface](#);
- [iterative sparse solvers \(ISS\)](#) based on the reverse communication interface (RCI);
- and [two preconditioners](#) based on the incomplete LU factorization technique.

Intel MKL PARDISO - Parallel Direct Sparse Solver Interface

This section describes the interface to the shared-memory multiprocessing parallel direct sparse solver known as the Intel MKL PARDISO solver.

The Intel MKL PARDISO package is a high-performance, robust, memory efficient, and easy to use software package for solving large sparse linear systems of equations on shared memory multiprocessors. The solver uses a combination of left- and right-looking Level-3 BLAS supernode techniques [[Schenk00-2](#)]. To improve sequential and parallel sparse numerical factorization performance, the algorithms are based on a Level-3 BLAS update and pipelining parallelism is used with a combination of left- and right-looking supernode techniques [[Schenk00](#), [Schenk01](#), [Schenk02](#), [Schenk03](#)]. The parallel pivoting methods allow complete supernode pivoting to compromise numerical stability and scalability during the factorization process. For sufficiently large problem sizes, numerical experiments demonstrate that the scalability of the parallel algorithm is nearly independent of the shared-memory multiprocessing architecture.

The following table lists the names of the Intel MKL PARDISO routines and describes their general use.

Intel MKL PARDISO Routines

Routine	Description
pardisoinit	Initializes Intel MKL PARDISO with default parameters depending on the matrix type.
pardiso	Calculates the solution of a set of sparse linear equations with single or multiple right-hand sides.
pardiso_64	Calculates the solution of a set of sparse linear equations with single or multiple right-hand sides, 64-bit integer version.
pardiso_getenv	Retrieves additional values from the Intel MKL PARDISO handle.
pardiso_setenv	Sets additional values in the Intel MKL PARDISO handle.
mkl_pardiso_pivot	Replaces routine which handles Intel MKL PARDISO pivots with user-defined routine.
pardiso_getdiag	Returns diagonal elements of initial and factorized matrix.

Routine	Description
<code>pardiso_handle_store</code>	Store internal structures from <code>pardiso</code> to a file.
<code>pardiso_handle_restore</code>	Restore <code>pardiso</code> internal structures from a file.
<code>pardiso_handle_delete</code>	Delete files with <code>pardiso</code> internal structure data.
<code>pardiso_handle_store_64</code>	Store internal structures from <code>pardiso_64</code> to a file.
<code>pardiso_handle_restore_64</code>	Restore <code>pardiso_64</code> internal structures from a file.
<code>pardiso_handle_delete_64</code>	Delete files with <code>pardiso_64</code> internal structure data.

The Intel MKL PARDISO solver supports a wide range of real and complex sparse matrix types (see [the figure below](#)).

Sparse Matrices That Can Be Solved with the Intel MKL PARDISO Solver

The Intel MKL PARDISO solver performs four tasks:

- analysis and symbolic factorization
- numerical factorization
- forward and backward substitution including iterative refinement
- termination to release all internal solver memory.

You can find code examples that use Intel MKL PARDISO routines to solve systems of linear equations in the `examples` folder of the Intel MKL installation directory:

- `examples/solverc/source`

Supported Matrix Types

The analysis steps performed by Intel MKL PARDISO depend on the structure of the input matrix A .

Symmetric Matrices

The solver first computes a symmetric fill-in reducing permutation P based on either the minimum degree algorithm [Liu85] or the nested dissection algorithm from the METIS package [Karypis98] (both included with Intel MKL), followed by the parallel left-right looking numerical Cholesky factorization [Schenk00-2] of $PAP^T = LL^T$ for symmetric positive-definite matrices, or $PAP^T = LDL^T$ for symmetric indefinite matrices. The solver uses diagonal pivoting, or 1x1 and 2x2 Bunch-Kaufman pivoting for symmetric indefinite matrices. An approximation of X is found by forward and backward substitution and optional iterative refinement.

Whenever numerically acceptable 1x1 and 2x2 pivots cannot be found within the diagonal supernode block, the coefficient matrix is perturbed. One or two passes of iterative refinement may be required to correct the effect of the perturbations. This restricting notion of pivoting with iterative refinement is effective for highly indefinite symmetric systems. Furthermore, for a large set of matrices from different applications areas, this method is as accurate as a direct factorization method that uses complete sparse pivoting techniques [Schenk04].

Another method of improving the pivoting accuracy is to use symmetric weighted matching algorithms. These algorithms identify large entries in the coefficient matrix A that, if permuted close to the diagonal, permit the factorization process to identify more acceptable pivots and proceed with fewer pivot perturbations. These algorithms are based on maximum weighted matchings and improve the quality of the factor in a complementary way to the alternative of using more complete pivoting techniques.

The inertia is also computed for real symmetric indefinite matrices.

Structurally Symmetric Matrices

The solver first computes a symmetric fill-in reducing permutation P followed by the parallel numerical factorization of $PAP^T = QLU^T$. The solver uses partial pivoting in the supernodes and an approximation of X is found by forward and backward substitution and optional iterative refinement.

Nonsymmetric Matrices

The solver first computes a nonsymmetric permutation P_{MPS} and scaling matrices D_r and D_c with the aim of placing large entries on the diagonal to enhance reliability of the numerical factorization process [Duff99]. In the next step the solver computes a fill-in reducing permutation P based on the matrix $P_{MPS}A + (P_{MPS}A)^T$ followed by the parallel numerical factorization

$$QLUR = PP_{MPS}D_rAD_cP$$

with supernode pivoting matrices Q and R . When the factorization algorithm reaches a point where it cannot factor the supernodes with this pivoting strategy, it uses a pivoting perturbation strategy similar to [Li99]. The magnitude of the potential pivot is tested against a constant threshold of

$$\alpha = \epsilon \cdot ||A2||_{\text{inf}},$$

where ϵ is the machine precision, $A2 = P \cdot P_{MPS} \cdot D_r \cdot A \cdot D_c \cdot P$, and $||A2||_{\text{inf}}$ is the infinity norm of A . Any tiny pivots encountered during elimination are set to the sign $(1_{IT}) \cdot \epsilon \cdot ||A2||_{\text{inf}}$, which trades off some numerical stability for the ability to keep pivots from getting too small. Although many failures could render the factorization well-defined but essentially useless, in practice the diagonal elements are rarely modified for a large class of matrices. The result of this pivoting approach is that the factorization is, in general, not exact and iterative refinement may be needed.

Sparse Data Storage

Sparse data storage in Intel MKL PARDISO follows the 3-array variation of the compressed sparse row (CSR3) format described in [Three Array Variation of CSR Format](#) or the three-array variation of the block compressed sparse row (BSR3) format described in [Three Array Variation of BSR Format](#). The Intel MKL PARDISO parameter ja is used for the *columns* array, ia is used for *rowIndex*, and a is used for *values*. The algorithms in Intel MKL PARDISO require column indices ja to be in increasing order per row and that the diagonal element in each row be present for any structurally symmetric matrix. For symmetric or nonsymmetric matrices the diagonal elements which are equal to zero are not necessary. For BSR3 format, use [iparm\[36\]](#) to specify the block size.

CAUTION

Intel MKL PARDISO column indices *ja* must be in increasing order per row. You can validate the sparse matrix structure with the matrix checker ([iparm\[26\]](#))

NOTE

While the presence of zero diagonal elements for symmetric matrices is not required, you should explicitly set zero diagonal elements for symmetric matrices. Otherwise, Intel MKL PARDISO creates internal copies of arrays *ia*, *ja*, and *a* full of diagonal elements, which require additional memory and computational time. However, the memory and time required the diagonal elements in internal arrays is usually not significant compared to the memory and the time required to factor and solve the matrix.

Storage of Matrices

By default, Intel MKL PARDISO stores matrices in RAM. However, you can specify that Intel MKL PARDISO store matrices on disk by setting [iparm\[59\]](#). This is referred to as in-core (IC) and out-of-core (OOC), respectively.

OOC parameters can be set in a configuration file. You can set the path to this file and its name using environmental variables `MKL_PARDISO_OOC_CFG_PATH` and `MKL_PARDISO_OOC_CFG_FILE_NAME`.

These variables specify the path and filename as follows:

`<MKL_PARDISO_OOC_CFG_PATH>/<MKL_PARDISO_OOC_CFG_FILE_NAME>` for Linux* OS and OS X*, and
`<MKL_PARDISO_OOC_CFG_PATH>\<MKL_PARDISO_OOC_CFG_FILE_NAME>` for Windows* OS.

By default, the name of the file is `pardiso_ooc.cfg` and it is placed in the current directory.

All temporary data files can be deleted or stored when the calculations are completed in accordance with the value of the environmental variable `MKL_PARDISO_OOC_KEEP_FILE`. If it is not set or if it is set to 1, then all files are deleted. If it is set to 0, then all files are stored.

By default, the OOC version of Intel MKL PARDISO uses the current directory for storing data, and all work arrays associated with the matrix factors are stored in files named `ooc_temp` with different extensions. These default values can be changed by using the environmental variable `MKL_PARDISO_OOC_PATH`.

To set the environmental variables `MKL_PARDISO_OOC_MAX_CORE_SIZE`, `MKL_PARDISO_OOC_MAX_SWAP_SIZE`, `MKL_PARDISO_OOC_KEEP_FILE`, and `MKL_PARDISO_OOC_PATH`, create the configuration file with the following lines:

```
MKL_PARDISO_OOC_PATH = <path>\ooc_file
MKL_PARDISO_OOC_MAX_CORE_SIZE = N
MKL_PARDISO_OOC_MAX_SWAP_SIZE = K
MKL_PARDISO_OOC_KEEP_FILE = 0 (or 1)
```

where `<path>` is the directory for storing data, `ooc_file` is the file name without any extension, *N* is the maximum size of RAM in megabytes available for Intel MKL PARDISO (default value is 2000 MB), *K* is the maximum swap size in megabytes available for Intel MKL PARDISO (default value is 0 MB). Do not set *N+K* greater than the size of the RAM plus the size of the swap. Be sure to allow enough free memory for the operating system and any other processes which are necessary.

CAUTION

The maximum length of the path lines in the configuration files is 1000 characters.

Alternatively the environment variables can be set via command line.

For Linux* OS and OS X*:

```
export MKL_PARDISO_OOC_PATH = <path>/ooc_file
export MKL_PARDISO_OOC_MAX_CORE_SIZE = N
export MKL_PARDISO_OOC_MAX_SWAP_SIZE = K
export MKL_PARDISO_OOC_KEEP_FILE = 0 (or 1)
```

For Windows* OS:

```
set MKL_PARDISO_OOC_PATH = <path>\ooc_file
set MKL_PARDISO_OOC_MAX_CORE_SIZE = N
set MKL_PARDISO_OOC_MAX_SWAP_SIZE = K
set MKL_PARDISO_OOC_KEEP_FILE = 0 (or 1)
```

NOTE

The values specified in a command line have higher priorities: if a variable is changed in the configuration file and in the command line, OOC version of Intel MKL PARDISO uses only the value defined in the command line.

Direct-Iterative Preconditioning for Nonsymmetric Linear Systems

The solver uses a combination of direct and iterative methods [Sonn89] to accelerate the linear solution process for transient simulation. Most applications of sparse solvers require solutions of systems with gradually changing values of the nonzero coefficient matrix, but with an identical sparsity pattern. In these applications, the analysis phase of the solvers has to be performed only once and the numerical factorizations are the important time-consuming steps during the simulation. Intel MKL PARDISO uses a numerical factorization and applies the factors in a preconditioned Krylow-Subspace iteration. If the iteration does not converge, the solver automatically switches back to the numerical factorization. This method can be applied to nonsymmetric matrices in Intel MKL PARDISO. You can select the method using the *iparm*[3] input parameter. The *iparm*[19] parameter returns the error status after running Intel MKL PARDISO.

Single and Double Precision Computations

Intel MKL PARDISO solves tasks using single or double precision. Each precision has its benefits and drawbacks. Double precision variables have more digits to store value, so the solver uses more memory for keeping data. But this mode solves matrices with better accuracy, which is especially important for input matrices with large condition numbers.

Single precision variables have fewer digits to store values, so the solver uses less memory than in the double precision mode. Additionally this mode usually takes less time. But as computations are made less precisely, only some systems of equations can be solved accurately enough using single precision.

Separate Forward and Backward Substitution

The solver execution step (see *parameter**phase* = 33 below) can be divided into two or three separate substitutions: forward, backward, and possible diagonal. This separation can be explained by the examples of solving systems with different matrix types.

A real symmetric positive definite matrix A (*mtype* = 2) is factored by Intel MKL PARDISO as $A = L^*L^T$. In this case the solution of the system $A^*x=b$ can be found as sequence of substitutions: $L^*y=b$ (forward substitution, *phase* = 331) and $L^T*x=y$ (backward substitution, *phase* = 333).

A real nonsymmetric matrix A (*mtype* = 11) is factored by Intel MKL PARDISO as $A = L^*U$. In this case the solution of the system $A^*x=b$ can be found by the following sequence: $L^*y=b$ (forward substitution, *phase* = 331) and $U^*x=y$ (backward substitution, *phase* = 333).

Solving a system with a real symmetric indefinite matrix A (*mtype* = -2) is slightly different from the cases above. Intel MKL PARDISO factors this matrix as $A=LDL^T$, and the solution of the system $A^*x=b$ can be calculated as the following sequence of substitutions: $L^*y=b$ (forward substitution, *phase* = 331), $D^*v=y$

(diagonal substitution, *phase* = 332), and finally $L^T * x = v$ (backward substitution, *phase* = 333). Diagonal substitution makes sense only for symmetric indefinite matrices (*mtype* = -2, -4, 6). For matrices of other types a solution can be found as described in the first two examples.

CAUTION

The number of refinement steps (*iparm*[7]) must be set to zero if a solution is calculated with separate substitutions (*phase* = 331, 332, 333), otherwise Intel MKL PARDISO produces the wrong result.

NOTE

Different pivoting (*iparm*[20]) produces different LDL^T factorization. Therefore results of forward, diagonal and backward substitutions with diagonal pivoting can differ from results of the same steps with Bunch-Kaufman pivoting. Of course, the final results of sequential execution of forward, diagonal and backward substitution are equal to the results of the full solving step (*phase*=33) regardless of the pivoting used.

Callback Function for Pivoting Control

In-core Intel MKL PARDISO allows you to control pivoting with a callback routine, [mkl_pardiso_pivot](#). You can then use the [pardiso_getdiag](#) routine to access the diagonal elements. Set *iparm*[55] to 1 in order to use the callback functionality.

pardiso

Calculates the solution of a set of sparse linear equations with single or multiple right-hand sides.

Syntax

```
void pardiso (_MKL_DSS_HANDLE_t pt, const MKL_INT *maxfct, const MKL_INT *mnum, const
MKL_INT *mtype, const MKL_INT *phase, const MKL_INT *n, const void *a, const MKL_INT
*ia, const MKL_INT *ja, MKL_INT *perm, const MKL_INT *nrhs, MKL_INT *iparm, const
MKL_INT *msglvl, void *b, void *x, MKL_INT *error);
```

Include Files

- mkl.h

Description

The routine `pardiso` calculates the solution of a set of sparse linear equations

$$A * X = B$$

with single or multiple right-hand sides, using a parallel LU , LDL , or LL^T factorization, where A is an n -by- n matrix, and X and B are n -by-*nrhs* vectors or matrices.

NOTE

This routine supports the Progress Routine feature. See [Progress Function](#) section for details.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

pt Array with size of 64.
Handle to internal data structure. The entries must be set to zero prior to the first call to `pardiso`. Unique for factorization.

CAUTION

After the first call to `pardiso` do not directly modify *pt*, as that could cause a serious memory leak.

Use the `pardiso_handle_store` or `pardiso_handle_store_64` routine to store the content of *pt* to a file. Restore the contents of *pt* from the file using `pardiso_handle_restore` or `pardiso_handle_restore_64`. Use `pardiso_handle_store` and `pardiso_handle_restore` with `pardiso`, and `pardiso_handle_store_64` and `pardiso_handle_restore_64` with `pardiso_64`.

maxfct Maximum number of factors with identical sparsity structure that must be kept in memory at the same time. In most applications this value is equal to 1. It is possible to store several different factorizations with the same nonzero structure at the same time in the internal data structure management of the solver.

`pardiso` can process several matrices with an identical matrix sparsity pattern and it can store the factors of these matrices at the same time. Matrices with a different sparsity structure can be kept in memory with different memory address pointers *pt*.

mnum Indicates the actual matrix for the solution phase. With this scalar you can define which matrix to factorize. The value must be: $1 \leq mnum \leq maxfct$.

In most applications this value is 1.

mtype Defines the matrix type, which influences the pivoting method. The Intel MKL PARDISO solver supports the following matrices:

1	real and structurally symmetric
2	real and symmetric positive definite
-2	real and symmetric indefinite

3	complex and structurally symmetric
4	complex and Hermitian positive definite
-4	complex and Hermitian indefinite
6	complex and symmetric
11	real and nonsymmetric
13	complex and nonsymmetric

phase

Controls the execution of the solver. Usually it is a two- or three-digit integer. The first digit indicates the starting phase of execution and the second digit indicates the ending phase. Intel MKL PARDISO has the following phases of execution:

- Phase 1: Fill-reduction analysis and symbolic factorization
- Phase 2: Numerical factorization
- Phase 3: Forward and Backward solve including optional iterative refinement

This phase can be divided into two or three separate substitutions: forward, backward, and diagonal (see [Separate Forward and Backward Substitution](#)).

- Memory release phase (*phase*= 0 or *phase*= -1)

If a previous call to the routine has computed information from previous phases, execution may start at any phase. The *phase* parameter can have the following values:

<i>phase</i>	Solver Execution Steps
11	Analysis
12	Analysis, numerical factorization
13	Analysis, numerical factorization, solve, iterative refinement
22	Numerical factorization
23	Numerical factorization, solve, iterative refinement
33	Solve, iterative refinement
331	like <i>phase</i> =33, but only forward substitution
332	like <i>phase</i> =33, but only diagonal substitution (if available)
333	like <i>phase</i> =33, but only backward substitution
0	Release internal memory for <i>L</i> and <i>U</i> matrix number <i>mnum</i>
-1	Release all internal memory for all matrices

If $iparm[35] = 0$, phases 331, 332, and 333 perform this decomposition:

$$A = \begin{bmatrix} L_{11} & 0 \\ L_{12} & L_{22} \end{bmatrix} \begin{bmatrix} D_{11} & 0 \\ 0 & D_{22} \end{bmatrix} \begin{bmatrix} U_{11} & U_{21} \\ 0 & U_{22} \end{bmatrix}$$

If $iparm[35] = 2$, phases 331, 332, and 333 perform a different decomposition:

$$A = \begin{bmatrix} L_{11} & 0 \\ L_{12} & I \end{bmatrix} \begin{bmatrix} I & 0 \\ 0 & S \end{bmatrix} \begin{bmatrix} U_{11} & U_{21} \\ 0 & I \end{bmatrix}$$

You can supply a custom implementation for phase 332 instead of calling `pardiso`. For example, it can be implemented with dense LAPACK functionality. Custom implementation also allows you to substitute the matrix S with your own.

NOTE

For very large Schur complement matrices use LAPACK functionality to compute the Schur complement vector instead of the Intel MKL PARDISO phase 332 implementation.

n

Number of equations in the sparse linear systems of equations $A^*X = B$.
Constraint: $n > 0$.

a

Array. Contains the non-zero elements of the coefficient matrix A corresponding to the indices in ja . The coefficient matrix can be either real or complex. The matrix must be stored in the three-array variant of the compressed sparse row (CSR3) or in the three-array variant of the block compressed sparse row (BSR3) format, and the matrix must be stored with increasing values of ja for each row.

For CSR3 format, the size of a is the same as that of ja . Refer to the *values* array description in [Three Array Variation of CSR Format](#) for more details.

For BSR3 format the size of a is the size of ja multiplied by the square of the block size. Refer to the *values* array description in [Three Array Variation of BSR Format](#) for more details.

ia

Array, size $(n+1)$.

For CSR3 format, $ia[i]$ ($i < n$) points to the first column index of row i in the array ja . That is, $ia[i]$ gives the index of the element in array a that contains the first non-zero element from row i of A . The last element $ia[n]$ is taken to be equal to the number of non-zero elements in A , plus one. Refer to *rowIndex* array description in [Three Array Variation of CSR Format](#) for more details.

For BSR3 format, $ia[i]$ ($i < n$) points to the first column index of row i in the array ja . That is, $ia[i]$ gives the index of the element in array a that contains the first non-zero block from row i of A . The last element $ia[n]$ is taken to be equal to the number of non-zero blocks in A , plus one. Refer to *rowIndex* array description in [Three Array Variation of BSR Format](#) for more details.

The array *ia* is accessed in all phases of the solution process.

Indexing of *ia* is one-based by default, but it can be changed to zero-based by setting the appropriate value to the parameter [iparm\[34\]](#).

ja

For CSR3 format, array *ja* contains column indices of the sparse matrix *A*. It is important that the indices are in increasing order per row. For structurally symmetric matrices it is assumed that all diagonal elements are stored (even if they are zeros) in the list of non-zero elements in *a* and *ja*. For symmetric matrices, the solver needs only the upper triangular part of the system as is shown for *columns* array in [Three Array Variation of CSR Format](#).

For BSR3 format, array *ja* contains column indices of the sparse matrix *A*. It is important that the indices are in increasing order per row. For structurally symmetric matrices it is assumed that all diagonal blocks are stored (even if they are zeros) in the list of non-zero blocks in *a* and *ja*. For symmetric matrices, the solver needs only the upper triangular part of the system as is shown for *columns* array in [Three Array Variation of BSR Format](#).

The array *ja* is accessed in all phases of the solution process.

Indexing of *ja* is one-based by default, but it can be changed to zero-based by setting the appropriate value to the parameter [iparm\[34\]](#).

perm

Array, size (*n*). Depending on the value of [iparm\[4\]](#) and [iparm\[30\]](#), either holds the permutation vector of size *n* or specifies elements used for computing a partial solution.

- If [iparm\[4\]](#) = 1, [iparm\[30\]](#) = 0, and [iparm\[35\]](#) = 0, *perm* specifies the fill-in reducing ordering to the solver. Let *A* be the original matrix and $C = P^* A^* P^T$ be the permuted matrix. Row (column) *i* of *C* is the *perm[i]* row (column) of *A*. The array *perm* is also used to return the permutation vector calculated during fill-in reducing ordering stage.

NOTE

Be aware that setting [iparm\[4\]](#) = 1 prevents use of a parallel algorithm for the solve step.

- If [iparm\[4\]](#) = 2, [iparm\[30\]](#) = 0, and [iparm\[35\]](#) = 0, the permutation vector computed in phase 11 is returned in the *perm* array.
- If [iparm\[4\]](#) = 0, [iparm\[30\]](#) > 0, and [iparm\[35\]](#) = 0, *perm* specifies elements of the right-hand side to use or of the solution to compute for a partial solution.
- If [iparm\[4\]](#) = 0, [iparm\[30\]](#) = 0, and [iparm\[35\]](#) > 0, *perm* specifies elements for a Schur complement.

See [iparm\[4\]](#) and [iparm\[30\]](#) for more details.

Indexing of *perm* is one-based by default, but it can be changed to zero-based by setting the appropriate value to the parameter [iparm\[34\]](#).

nrhs

Number of right-hand sides that need to be solved for.

<i>iparm</i>	Array, size (64). This array is used to pass various parameters to Intel MKL PARDISO and to return some useful information after execution of the solver. See pardiso iparm Parameter for more details about the <i>iparm</i> parameters.
<i>msglvl</i>	Message level information. If <i>msglvl</i> = 0 then <i>pardiso</i> generates no output, if <i>msglvl</i> = 1 the solver prints statistical information to the screen.
<i>b</i>	Array, size ($n \times nrhs$). On entry, contains the right-hand side vector/matrix <i>B</i> , which is placed in memory contiguously. The <i>b</i> [$+k \times nrhs$] element must hold the <i>i</i> -th component of <i>k</i> -th right-hand side vector. Note that <i>b</i> is only accessed in the solution phase.

Output Parameters

(See also [Intel MKL PARDISO Parameters in Tabular Form.](#))

<i>pt</i>	Handle to internal data structure.
<i>perm</i>	See the Input Parameter description of the <i>perm</i> array.
<i>iparm</i>	On output, some <i>iparm</i> values report information such as the numbers of non-zero elements in the factors. See pardiso iparm Parameter for more details about the <i>iparm</i> parameters.
<i>b</i>	On output, the array is replaced with the solution if <i>iparm</i> [5] = 1.
<i>x</i>	Array, size ($n \times nrhs$). If <i>iparm</i> [5]=0 it contains solution vector/matrix <i>X</i> , which is placed contiguously in memory. The <i>x</i> [$i + k \times n$] element must hold the <i>i</i> -th component of the <i>k</i> -th solution vector. Note that <i>x</i> is only accessed in the solution phase.
<i>error</i>	The error indicator according to the below table:

error	Information
0	no error
-1	input inconsistent
-2	not enough memory
-3	reordering problem
-4	zero pivot, numerical factorization or iterative refinement problem
-5	unclassified (internal) error
-6	reordering failed (matrix types 11 and 13 only)
-7	diagonal matrix is singular
-8	32-bit integer overflow problem

error	Information
-9	not enough memory for OOC
-10	error opening OOC files
-11	read/write error with OOC files
-12	(pardiso_64 only) pardiso_64 called from 32-bit library

pardisoinit

Initialize Intel MKL PARDISO with default parameters in accordance with the matrix type.

Syntax

```
void pardisoinit (_MKL_DSS_HANDLE_t pt, const MKL_INT *mtype, MKL_INT *iparm );
```

Include Files

- mkl.h

Description

This function initializes Intel MKL PARDISO internal address pointer *pt* with zero values (as needed for the very first call of *pardiso*) and sets default *iparm* values in accordance with the matrix type. Intel MKL supplies the *pardisoinit* routine to be compatible with PARDISO 3.2 or lower.

NOTE

An alternative way to set default *iparm* values is to call *pardiso* in the analysis phase with *iparm*(1)=0. In this case you must initialize the internal address pointer *pt* with zero values manually.

NOTE

The *pardisoinit* routine initializes only the in-core version of Intel MKL PARDISO. Switching on the out-of core version of Intel MKL PARDISO as well as changing default *iparm* values can be done after the call to *pardisoinit* but before the first call to *pardiso*.

Input Parameters

<i>perm</i>	Ignored.
<i>mtype</i>	This scalar value defines the matrix type. Based on this value <i>pardisoinit</i> sets default values for the <i>iparm</i> array. Refer to the section Intel MKL PARDISO Parameters in Tabular Form for more details about the default values of Intel MKL PARDISO

Output Parameters

pt Array with a dimension of 64. Solver internal data address pointer. These addresses are passed to the solver, and all related internal memory management is organized through this array. The `pardisoinit` routine nullifies the array *pt*.

NOTE

It is very important that the pointer *pt* is initialized with zero before the first call of Intel MKL PARDISO. After that first call you should never modify the pointer, because it could cause a serious memory leak or a crash.

iparm Array with a dimension of 64. This array is used to pass various parameters to Intel MKL PARDISO and to return some useful information after execution of the solver. The `pardisoinit` routine fills-in the *iparm* array with the default values. Refer to the section [Intel MKL PARDISO Parameters in Tabular Form](#) for more details about the default values of Intel MKL PARDISO.

pardiso_64

Calculates the solution of a set of sparse linear equations with single or multiple right-hand sides, 64-bit integer version.

Syntax

```
void pardiso_64 (_MKL_DSS_HANDLE_t pt, const long long int *maxfct, const long long int *mnum, const long long int *mtype, const long long int *phase, const long long int *n, const void *a, const long long int *ia, const long long int *ja, long long int *perm, const long long int *nrhs, long long int *iparm, const long long int *msglvl, void *b, void *x, long long int *error);
```

Include Files

- `mkl.h`

Description

`pardiso_64` is an alternative ILP64 (64-bit integer) version of the `pardiso` routine (see [Description](#) section for more details). The interface of `pardiso_64` is the same as the interface of `pardiso`, but it accepts and returns all integer data as `long long int`.

Use `pardiso_64` when `pardiso` for solving large matrices (with the number of non-zero elements on the order of 500 million or more). You can use it together with the usual LP64 interfaces for the rest of Intel MKL functionality. In other words, if you use 64-bit integer version (`pardiso_64`), you do not need to re-link your applications with ILP64 libraries. Take into account that `pardiso_64` may perform slower than regular `pardiso` on the reordering and symbolic factorization phase.

NOTE

`pardiso_64` is supported only in the 64-bit libraries. If `pardiso_64` is called from the 32-bit libraries, it returns `error == -12`.

NOTE

This routine supports the Progress Routine feature. See [Progress Function](#) section for details.

Input Parameters

The input parameters of `pardiso_64` are the same as the input parameters of `pardiso`, but `pardiso_64` accepts all integer data as `long long int`.

Output Parameters

The output parameters of `pardiso_64` are the same as the [output parameters of `pardiso`](#), but `pardiso_64` returns all integer data as `long long int`.

`pardiso_getenv, pardiso_setenv`

Retrieves additional values from or sets additional values in the Intel MKL PARDISO handle.

Syntax

```
MKL_INT pardiso_getenv (const _MKL_DSS_HANDLE_t handle, const enum PARDISO_ENV_PARAM
*param, char *value);
```

```
MKL_INT pardiso_setenv (_MKL_DSS_HANDLE_t handle , const enum PARDISO_ENV_PARAM *param,
const char *value);
```

Include Files

- `mkh.h`

Description

These functions operate with the Intel MKL PARDISO handle. The `pardiso_getenv` routine retrieves additional values from the Intel MKL PARDISO handle, and `pardiso_setenv` sets specified values in the Intel MKL PARDISO handle.

These functions enable retrieving and setting the name of the Intel MKL PARDISO OOC file.

To retrieve the Intel MKL PARDISO OOC file name, you can apply this function to any properly-created handle.

To set the Intel MKL PARDISO OOC file name in the handle you must call the function before the reordering stage. This is because the OOC file name is stored in the handle after the reordering stage and it is not changed during further computations.

NOTE

A 1024-byte internal buffer is used inside Intel MKL PARDISO for storing the OOC file name. Allocate a 1024-byte buffer for passing to the `pardiso_getenv` function as the `value` parameter.

Input Parameters

handle Intel MKL PARDISO handle for which to set and from which to retrieve information. (See [DSS Interface Description](#) for structure description)

param Specifies the required parameter. The only value is `PARDISO_OCC_FILE_NAME`, defined in the corresponding include file.

value Input parameter for `pardiso_setenv`. Contains the name of the OOC file that must be used in the handle.

Output Parameters

handle Output parameter for `pardiso_setenv`. Data object of the MKL_DSS_HANDLE type (see [DSS Interface Description](#)).

value Output parameter for `pardiso_getenv`. Contains the name of the OOC file that must be used in the handle.

mkl_pardiso_pivot

Replaces routine which handles Intel MKL PARDISO pivots with user-defined routine.

Syntax

```
void mkl_pardiso_pivot (const void *ai, void *bi, const void *eps);
```

Include Files

- `mkl.h`

Description

The `mkl_pardiso_pivot` routine allows you to handle diagonal elements which arise during numerical factorization that are zero or near zero. By default, Intel MKL PARDISO determines that a diagonal element *bi* is a pivot if $bi < eps$, and if so, replaces it with *eps*. But you can provide your own routine to modify the resulting factorized matrix in case there are small elements on the diagonal during the factorization step.

NOTE

To use this routine, you must set `iparm[55]` to 1 before the main `pardiso` loop.

Input Parameters

ai Diagonal element of initial matrix corresponding to pivot element.

bi Diagonal element of factorized matrix that could be chosen as a pivot element.

eps Scalar to compare with diagonal of factorized matrix. On input equal to parameter described by `iparm[9]`.

Output Parameters

bi In case element is chosen as a pivot, value with which to replace the pivot.

pardiso_getdiag

Returns diagonal elements of initial and factorized matrix.

Syntax

```
void pardiso_getdiag (const _MKL_DSS_HANDLE_t pt, void *df, void *da, const MKL_INT
*mnum, MKL_INT *error);
```

Include Files

- mkl.h

Description

This routine returns the diagonal elements of the initial and factorized matrix for a real or Hermitian matrix.

NOTE

In order to use this routine, you must set `iparm[55]` to 1 before the main `pardiso` loop.

Input Parameters

<i>pt</i>	Array with a size of 64. Handle to internal data structure for the Intel MKL PARDISO solver. The entries must be set to zero prior to the first call to <code>pardiso</code> . Unique for factorization.
<i>mnum</i>	Indicates the actual matrix for the solution phase of the Intel MKL PARDISO solver. With this scalar you can define the diagonal elements of the factorized matrix that you want to obtain. The value must be: 1 $\leq mnum \leq maxfct$. In most applications this value is 1.

Output Parameters

<i>df</i>	Array with a dimension of <i>n</i> . Contains diagonal elements of the factorized matrix after factorization.

NOTE

Elements of *df* correspond to diagonal elements of matrix *L* computed during phase 22. Because during phase 22 Intel MKL PARDISO makes additional permutations to improve stability, it is possible that array *df* is not in line with the *perm* array computed during phase 11.

<i>da</i>	Array with a dimension of <i>n</i> . Contains diagonal elements of the initial matrix.

NOTE

Elements of *da* correspond to diagonal elements of matrix *L* computed during phase 22. Because during phase 22 Intel MKL PARDISO makes additional permutations to improve stability, it is possible that array *da* is not in line with the *perm* array computed during phase 11.

<i>error</i>	The error indicator.

error	Information
0	no error

error

-1

Information

Diagonal information not turned on before `pardiso` main loop (`iparm[55]=0`).

`pardiso_handle_store`

Store internal structures from `pardiso` to a file.

Syntax

```
void pardiso_handle_store (_MKL_DSS_HANDLE_t pt, const char *dirname, MKL_INT *error);
```

Include Files

- `mkl.h`

Description

This function stores Intel MKL PARDISO structures to a file, allowing you to store Intel MKL PARDISO internal structures between the stages of the `pardiso` routine. The `pardiso_handle_restore` routine can restore the Intel MKL PARDISO internal structures from the file.

Input Parameters

<code>pt</code>	Array with a size of 64. Handle to internal data structure.
<code>dirname</code>	String containing the name of the directory to which to write the files with the content of the internal structures. Use an empty string ("") to specify the current directory. The routine creates a file named <code>handle.pds</code> in the directory.

Output Parameters

<code>pt</code>	Handle to internal data structure.
<code>error</code>	The error indicator.

error

0

Information

No error.

-2

Not enough memory.

-10

Cannot open file for writing.

-11

Error while writing to file.

-13

Wrong file format.

`pardiso_handle_restore`

Restore `pardiso` internal structures from a file.

Syntax

```
void pardiso_handle_restore (_MKL_DSS_HANDLE_t pt, const char *dirname, MKL_INT *error);
```

Include Files

- `mk1.h`

Description

This function restores Intel MKL PARDISO structures from a file. This allows you to restore Intel MKL PARDISO internal structures stored by `pardiso_handle_store` after a phase of the `pardiso` routine and continue execution of the next phase.

Input Parameters

<i>dirname</i>	String containing the name of the directory in which the file with the content of the internal structures are located. Use an empty string ("") to specify the current directory.

Output Parameters

<i>pt</i>	Array with a dimension of 64. Handle to internal data structure.

<i>error</i>	The error indicator.

error	Information
0	No error.
-2	Not enough memory.
-10	Cannot open file for reading.
-11	Error while reading from file.
-13	Wrong file format.

`pardiso_handle_delete`

Delete files with `pardiso` internal structure data.

Syntax

```
void pardiso_handle_delete (const char *dirname, MKL_INT *error);
```

Include Files

- `mk1.h`

Description

This function deletes files generated with `pardiso_handle_store` that contain Intel MKL PARDISO internal structures.

Input Parameters

<i>dirname</i>	String containing the name of the directory in which the file with the content of the internal structures are located. Use an empty string ("") to specify the current directory.

Output Parameters

<i>error</i>	The error indicator.	
error	Information	
0	No error.	
-10	Cannot delete files.	

pardiso_handle_store_64

Store internal structures from `pardiso_64` to a file.

Syntax

```
void pardiso_handle_store_64 (_MKL_DSS_HANDLE_t pt, const char *dirname, MKL_INT
*error);
```

Include Files

- `mkl.h`

Description

This function stores Intel MKL PARDISO structures to a file, allowing you to store Intel MKL PARDISO internal structures between the stages of the [pardiso_64](#) routine. The [pardiso_handle_restore_64](#) routine can restore the Intel MKL PARDISO internal structures from the file.

Input Parameters

<i>pt</i>	Array with a dimension of 64. Handle to internal data structure.
<i>dirname</i>	String containing the name of the directory to which to write the files with the content of the internal structures. Use an empty string ("") to specify the current directory. The routine creates a file named <code>handle.pds</code> in the directory.

Output Parameters

<i>pt</i>	Handle to internal data structure.
<i>error</i>	The error indicator.
error	Information
0	No error.
-2	Not enough memory.
-10	Cannot open file for writing.
-11	Error while writing to file.
-12	Not supported in 32-bit library - routine is only supported in 64-bit libraries.
-13	Wrong file format.

pardiso_handle_restore_64

Restore pardiso_64 internal structures from a file.

Syntax

```
void pardiso_handle_restore_64 (_MKL_DSS_HANDLE_t pt, const char *dirname, MKL_INT *error);
```

Include Files

- mkl.h

Description

This function restores Intel MKL PARDISO structures from a file. This allows you to restore Intel MKL PARDISO internal structures stored by `pardiso_handle_store_64` after a phase of the `pardiso_64` routine and continue execution of the next phase.

Input Parameters

<i>dirname</i>	String containing the name of the directory in which the file with the content of the internal structures are located. Use an empty string ("") to specify the current directory.

Input Parameters

<i>pt</i>	Array with a dimension of 64. Handle to internal data structure.

<i>error</i>	The error indicator.

error	Information
0	No error.
-2	Not enough memory.
-10	Cannot open file for reading.
-11	Error while reading from file.
-13	Wrong file format.

pardiso_handle_delete_64

Syntax

Delete files with `pardiso_64` internal structure data.

```
void pardiso_handle_delete_64 (const char *dirname, MKL_INT *error);
```

Include Files

- mkl.h

Description

This function deletes files generated with `pardiso_handle_store_64` that contain Intel MKL PARDISO internal structures.

Input Parameters

dirname String containing the name of the directory in which the file with the content of the internal structures are located. Use an empty string ("") to specify the current directory.

Output Parameters

error The error indicator.

error	Information
0	No error.
-10	Cannot delete files.
-12	Not supported in 32-bit library - routine is only supported in 64-bit libraries.

Intel MKL PARDISO Parameters in Tabular Form

The following table lists all parameters of Intel MKL PARDISO and gives their brief descriptions.

Parameter	Type	Description	Values	Comments	In/Out
<i>pt</i>	void*	Solver internal data address pointer	0	Must be initialized with zeros and never be modified later	in/out
<i>maxfct</i>	MKL_INT*	Maximal number of factors in memory	>0	Generally used value is 1	in
<i>mnum</i>	MKL_INT*	The number of matrix (from 1 to <i>maxfct</i>) to solve	[1: <i>maxfct</i>]	Generally used value is 1	in
<i>mtype</i>	MKL_INT*	Matrix type	1 2 -2 3 4 -4 6 11	Real and structurally symmetric Real and symmetric positive definite Real and symmetric indefinite Complex and structurally symmetric Complex and Hermitian positive definite Complex and Hermitian indefinite Complex and symmetric matrix Real and nonsymmetric matrix	in

Parameter	Type	Description	Values	Comments	In/Out
<i>phase</i>	MKL_INT*	Controls the execution of the solver For <i>iparm</i> [35] > 0, phases 331, 332, and 333 perform a different decomposition. See the <i>phase</i> parameter of pardiso for details.	13	Complex and nonsymmetric matrix	in
			11	Analysis	
			12	Analysis, numerical factorization	
			13	Analysis, numerical factorization, solve	
			22	Numerical factorization	
			23	Numerical factorization, solve	
			33	Solve, iterative refinement	
			331	<i>phase</i> =33, but only forward substitution	
			332	<i>phase</i> =33, but only diagonal substitution	
			333	<i>phase</i> =33, but only backward substitution	
			0	Release internal memory for L and U of the matrix number <i>mnum</i>	
			-1	Release all internal memory for all matrices	
<i>n</i>	MKL_INT*	Number of equations in the sparse linear system $A \cdot X = B$	>0		in
<i>a</i>	void*	Contains the non-zero elements of the coefficient matrix <i>A</i>	*	The size of <i>a</i> is the same as that of <i>ja</i> , and the coefficient matrix can be either real or complex. The matrix must be stored in the 3-array variation of compressed sparse row (CSR3) format with increasing values of <i>ja</i> for each row	in
<i>ia</i> [<i>n</i>]	MKL_INT*	<i>rowIndex</i> array in CSR3 format	>=0	<i>ia</i> [<i>i</i>] gives the index of the element in array <i>a</i> that contains the first non-zero element from row <i>i</i> of <i>A</i> . The last element <i>ia</i> (<i>n</i>) is taken to be equal to the number of non-zero elements in <i>A</i> .	in

Parameter	Type	Description	Values	Comments	In/ Out
<i>ja</i>	MKL_INT*	<i>columns</i> array in CSR3 format	>=0	Note: <i>iparm</i>[34] indicates whether row/column indexing starts from 1 or 0. The column indices for each row of <i>A</i> must be sorted in increasing order. For structurally symmetric matrices zero diagonal elements must be stored in <i>a</i> and <i>ja</i>. Zero diagonal elements should be stored for symmetric matrices, although they are not required. For symmetric matrices, the solver needs only the upper triangular part of the system. Note: <i>iparm</i>[34] indicates whether row/column indexing starts from 1 or 0.	in
<i>perm</i> [<i>n</i>]	MKL_INT*	Holds the permutation vector of size <i>n</i> or specifies elements used for computing a partial solution	>=0	You can apply your own fill-in reducing ordering (<i>iparm</i>[4] = 1) or return the permutation from the solver (<i>iparm</i>[4] = 2). Let $C = P^*A^*P^T$ be the permuted matrix. Row (column) <i>i</i> of <i>C</i> is the <i>perm</i>(<i>i</i>) row (column) of <i>A</i>. The numbering of the array must describe a permutation. To specify elements for a partial solution, set <i>iparm</i>[4] = 0, <i>iparm</i>[30] > 0, and <i>iparm</i>[35] = 0. To specify elements for a Schur complement, set <i>iparm</i>[4] = 0, <i>iparm</i>[30] = 0, and <i>iparm</i>[35] > 0. Note: <i>iparm</i>[34] indicates whether row/column indexing starts from 1 or 0.	in/ out
<i>nrhs</i>	MKL_INT*	Number of right-hand sides that need to be solved for	>=0	Generally used value is 1 To obtain better Intel MKL PARDISO performance, during the numerical factorization phase you	in

Parameter	Type	Description	Values	Comments	In/Out
<i>iparm</i> [64]	MKL_INT*	This array is used to pass various parameters to Intel MKL PARDISO and to return some useful information after execution of the solver (see pardiso iparm Parameter for more details)	*	can provide the maximum number of right-hand sides, which can be used further during the solving phase. If <i>iparm</i> [0]=0 , Intel MKL PARDISO fills <i>iparm</i> [1] through <i>iparm</i> [63] with default values and uses them.	in/ out
<i>msglvl</i>	MKL_INT*	Message level information	0 1	Intel MKL PARDISO generates no output Intel MKL PARDISO prints statistical information	in
<i>b</i> [<i>n*nrhs</i>]	void*	Right-hand side vectors	*	On entry, contains the right-hand side vector/ matrix <i>B</i> , which is placed contiguously in memory. The <i>b</i> [<i>i+k*n</i>] element must hold the <i>i</i> -th component of <i>k</i> -th right-hand side vector. Note that <i>b</i> is only accessed in the solution phase. On output, the array is replaced with the solution if iparm [5]=1.	in/ out
<i>x</i> [<i>n*nrhs</i>]	void*	Solution vectors	*	On output, if iparm [5]=0, contains solution vector/ matrix <i>X</i> which is placed contiguously in memory. The <i>x</i> [<i>i+k*n</i>] element must hold the <i>i</i> -th component of <i>k</i> -th solution vector. Note that <i>x</i> is only accessed in the solution phase.	out
<i>error</i>	MKL_INT*	Error indicator	0 -1 -2 -3 -4	No error Input inconsistent Not enough memory Reordering problem Zero pivot, numerical factorization or iterative refinement problem	out

Parameter	Type	Description	Values	Comments	In/ Out
			-5	Unclassified (internal) error	
			-6	Reordering failed (matrix types 11 and 13 only)	
			-7	Diagonal matrix is singular	
			-8	32-bit integer overflow problem	
			-9	Not enough memory for OOC	
			-10	Problems with opening OOC temporary files	
			-11	Read/write problems with the OOC data file	

¹⁾ See description of `PARDISO_DATA_TYPE` in [PARDISO_DATA_TYPE](#).

pardiso iparm Parameter

The following table describes all individual components of the Intel MKL PARDISO *iparm* parameter. Components which are not used must be initialized with 0. Default values are denoted with an asterisk (*).

Component	Description
<i>iparm</i> [0]	Use default values.
input	0 <i>iparm</i> [1] - <i>iparm</i> [63] are filled with default values.
	!=0 You must supply all values in components <i>iparm</i> [1] - <i>iparm</i> [63].
<i>iparm</i> [1]	Fill-in reducing ordering for the input matrix.
input	CAUTION You can control the parallel execution of the solver by explicitly setting the <code>MKL_NUM_THREADS</code> environment variable. If fewer OpenMP threads are available than specified, the execution may slow down instead of speeding up. If <code>MKL_NUM_THREADS</code> is not defined, then the solver uses all available processors.
	0 The minimum degree algorithm [Li99] .
	2* The nested dissection algorithm from the METIS package [Karypis98] .
	3 The parallel (OpenMP) version of the nested dissection algorithm. It can decrease the time of computations on multi-core computers, especially when Intel MKL PARDISO Phase 1 takes significant time.
	NOTE Setting <i>iparm</i>[1] = 3 prevents the use of CNR mode (<i>iparm</i>[33] > 0) because Intel MKL PARDISO uses dynamic parallelism.
<i>iparm</i> [2]	Reserved. Set to zero.
<i>iparm</i> [3]	Preconditioned CGS/CG.
input	

Component	Description								
	This parameter controls preconditioned CGS [Sonn89] for nonsymmetric or structurally symmetric matrices and Conjugate-Gradients for symmetric matrices. <i>iparm</i> [3] has the form <i>iparm</i> [3] = 10*L+K.								
K=0	The factorization is always computed as required by <i>phase</i> .								
K=1	CGS iteration replaces the computation of <i>LU</i> . The preconditioner is <i>LU</i> that was computed at a previous step (the first step or last step with a failure) in a sequence of solutions needed for identical sparsity patterns.								
K=2	CGS iteration for symmetric positive definite matrices replaces the computation of <i>LL^T</i> . The preconditioner is <i>LL^T</i> that was computed at a previous step (the first step or last step with a failure) in a sequence of solutions needed for identical sparsity patterns.								
The value <i>L</i> controls the stopping criterion of the Krylow-Subspace iteration: $\text{eps}_{\text{CGS}} = 10^{-L}$ is used in the stopping criterion $ dx_i / dx_0 < \text{eps}_{\text{CGS}}$ where $dx_i = \text{inv}(L*U)*r_i$ for <i>K</i> = 1 or $dx_i = \text{inv}(L*L^T)*r_i$ for <i>K</i> = 2 and <i>r_i</i> is the residue at iteration <i>i</i> of the preconditioned Krylow-Subspace iteration. A maximum number of 150 iterations is fixed with the assumption that the iteration will converge before consuming half the factorization time. Intermediate convergence rates and residue excursions are checked and can terminate the iteration process. If <i>phase</i> =23, then the factorization for a given <i>A</i> is automatically recomputed in cases where the Krylow-Subspace iteration failed, and the corresponding direct solution is returned. Otherwise the solution from the preconditioned Krylow-Subspace iteration is returned. Using <i>phase</i> =33 results in an error message (<i>error</i>=-4) if the stopping criteria for the Krylow-Subspace iteration can not be reached. More information on the failure can be obtained from iparm[19]. The default is <i>iparm</i>[3]=0, and other values are only recommended for an advanced user. <i>iparm</i>[3] must be greater than or equal to zero. Examples: <table> <tr> <th><i>iparm</i>[3]</th><th>Description</th></tr> <tr> <td>31</td><td><i>LU</i>-preconditioned CGS iteration with a stopping criterion of 1.0E-3 for nonsymmetric matrices</td></tr> <tr> <td>61</td><td><i>LU</i>-preconditioned CGS iteration with a stopping criterion of 1.0E-6 for nonsymmetric matrices</td></tr> <tr> <td>62</td><td><i>LL^T</i>-preconditioned CGS iteration with a stopping criterion of 1.0E-6 for symmetric positive definite matrices</td></tr> </table>		<i>iparm</i> [3]	Description	31	<i>LU</i> -preconditioned CGS iteration with a stopping criterion of 1.0E-3 for nonsymmetric matrices	61	<i>LU</i> -preconditioned CGS iteration with a stopping criterion of 1.0E-6 for nonsymmetric matrices	62	<i>LL^T</i> -preconditioned CGS iteration with a stopping criterion of 1.0E-6 for symmetric positive definite matrices
<i>iparm</i> [3]	Description								
31	<i>LU</i> -preconditioned CGS iteration with a stopping criterion of 1.0E-3 for nonsymmetric matrices								
61	<i>LU</i> -preconditioned CGS iteration with a stopping criterion of 1.0E-6 for nonsymmetric matrices								
62	<i>LL^T</i> -preconditioned CGS iteration with a stopping criterion of 1.0E-6 for symmetric positive definite matrices								
<i>iparm</i> [4] input	User permutation. This parameter controls whether user supplied fill-in reducing permutation is used instead of the integrated multiple-minimum degree or nested dissection algorithms. Another use of this parameter is to control obtaining the fill-in reducing permutation vector calculated during the reordering stage of Intel MKL PARDISO. This option is useful for testing reordering algorithms, adapting the code to special applications problems (for instance, to move zero diagonal elements to the end of P^*A*P^T), or for using the permutation vector more than once for matrices with identical sparsity structures. For definition of the permutation, see the description of the <i>perm</i> parameter.								

Component	Description
CAUTION You can only set one of <i>iparm</i> [4], <i>iparm</i> [30], and <i>iparm</i> [35], so be sure that the <i>iparm</i> [30] (partial solution) and the <i>iparm</i> [35] (Schur complement) parameters are 0 if you set <i>iparm</i> [4].	
0*	User permutation in the <i>perm</i> array is ignored.
1	Intel MKL PARDISO uses the user supplied fill-in reducing permutation from the <i>perm</i> array. <i>iparm</i> [1] is ignored.
NOTE Setting <i>iparm</i> [4] = 1 prevents use of a parallel algorithm for the solve step.	
2	Intel MKL PARDISO returns the permutation vector computed at phase 1 in the <i>perm</i> array.
<i>iparm</i> [5] input	Write solution on <i>x</i> .
NOTE The array <i>x</i> is always used.	
0*	The array <i>x</i> contains the solution; right-hand side vector <i>b</i> is kept unchanged.
1	The solver stores the solution on the right-hand side <i>b</i> .
<i>iparm</i> [6] output	Number of iterative refinement steps performed. Reports the number of iterative refinement steps that were actually performed during the solve step.
<i>iparm</i> [7] input	Iterative refinement step. On entry to the solve and iterative refinement step, <i>iparm</i> [7] must be set to the maximum number of iterative refinement steps that the solver performs.
0*	The solver automatically performs two steps of iterative refinement when perturbed pivots are obtained during the numerical factorization.
>0	Maximum number of iterative refinement steps that the solver performs. The solver performs not more than the absolute value of <i>iparm</i> [7] steps of iterative refinement. The solver might stop the process before the maximum number of steps if - a satisfactory level of accuracy of the solution in terms of backward error is achieved, - or if it determines that the required accuracy cannot be reached. In this case Intel MKL PARDISO returns -4 in the <i>error</i> parameter. The number of executed iterations is reported in <i>iparm</i> [6].
<0	Same as above, but the accumulation of the residuum uses extended precision real and complex data types. Perturbed pivots result in iterative refinement (independent of <i>iparm</i> [7]=0) and the number of executed iterations is reported in <i>iparm</i> [6].

Component	Description
<i>iparm</i> [8]	Reserved. Set to zero.
<i>iparm</i> [9]	Pivoting perturbation.
input	This parameter instructs Intel MKL PARDISO how to handle small pivots or zero pivots for nonsymmetric matrices (<i>mtype</i> =11 or <i>mtype</i> =13) and symmetric matrices (<i>mtype</i> =-2, <i>mtype</i> =-4, or <i>mtype</i> =6). For these matrices the solver uses a complete supernode pivoting approach. When the factorization algorithm reaches a point where it cannot factor the supernodes with this pivoting strategy, it uses a pivoting perturbation strategy similar to [Li99], [Schenk04]. Small pivots are perturbed with $\text{eps} = 10^{-iparm[9]}$. The magnitude of the potential pivot is tested against a constant threshold of $\alpha = \text{eps} * A2 _{inf},$ where $\text{eps} = 10^{(-iparm[9])}$, $A2 = P * P_{MPS} * D_r * A * D_c * P$, and $A2 _{inf}$ is the infinity norm of the scaled and permuted matrix <i>A</i>. Any tiny pivots encountered during elimination are set to the sign (<i>l_II</i>) * $\text{eps} * A2 _{inf}$, which trades off some numerical stability for the ability to keep pivots from getting too small. Small pivots are therefore perturbed with $\text{eps} = 10^{(-iparm[9])}$.
13*	The default value for nonsymmetric matrices(<i>mtype</i> =11, <i>mtype</i> =13), $\text{eps} = 10^{-13}$.
8*	The default value for symmetric indefinite matrices (<i>mtype</i> =-2, <i>mtype</i> =-4, <i>mtype</i> =6), $\text{eps} = 10^{-8}$.
<i>iparm</i> [10]	Scaling vectors.
input	Intel MKL PARDISO uses a maximum weight matching algorithm to permute large elements on the diagonal and to scale so that the diagonal elements are equal to 1 and the absolute values of the off-diagonal entries are less than or equal to 1. This scaling method is applied only to nonsymmetric matrices (<i>mtype</i> = 11 or <i>mtype</i> = 13). The scaling can also be used for symmetric indefinite matrices (<i>mtype</i> = -2, <i>mtype</i> =-4, or <i>mtype</i> = 6) when the symmetric weighted matchings are applied (<i>iparm</i>[12] = 1). Use <i>iparm</i>[10] = 1 (scaling) and <i>iparm</i>[12] = 1 (matching) for highly indefinite symmetric matrices, for example, from interior point optimizations or saddle point problems. Note that in the analysis phase (<i>phase</i>=11) you must provide the numerical values of the matrix <i>A</i> in array <i>a</i> in case of scaling and symmetric weighted matching.
0*	Disable scaling. Default for symmetric indefinite matrices.
1*	Enable scaling. Default for nonsymmetric matrices. Scale the matrix so that the diagonal elements are equal to 1 and the absolute values of the off-diagonal entries are less or equal to 1. This scaling method is applied to nonsymmetric matrices (<i>mtype</i> = 11, <i>mtype</i> = 13). The scaling can also be used for symmetric indefinite matrices (<i>mtype</i> = -2, <i>mtype</i> = -4, <i>mtype</i> = 6) when the symmetric weighted matchings are applied (<i>iparm</i>[12] = 1). Note that in the analysis phase (<i>phase</i>=11) you must provide the numerical values of the matrix <i>A</i> in case of scaling.
<i>iparm</i> [11]	Solve with transposed or conjugate transposed matrix <i>A</i> .
input	NOTE For real matrices the terms <i>transposed</i> and <i>conjugate transposed</i> are equivalent.
0*	Solve a linear system $AX = B$.

Component	Description
	1 Solve a conjugate transposed system $A^H X = B$ based on the factorization of the matrix A .
	2 Solve a transposed system $A^T X = B$ based on the factorization of the matrix A .
<i>iparm</i> [12] input	Improved accuracy using (non-) symmetric weighted matching. Intel MKL PARDISO can use a maximum weighted matching algorithm to permute large elements close the diagonal. This strategy adds an additional level of reliability to the factorization methods and complements the alternative of using more complete pivoting techniques during the numerical factorization.
	0* Disable matching. Default for symmetric indefinite matrices.
	1* Enable matching. Default for nonsymmetric matrices. Maximum weighted matching algorithm to permute large elements close to the diagonal. It is recommended to use <i>iparm</i> [10] = 1 (scaling) and <i>iparm</i> [12] = 1 (matching) for highly indefinite symmetric matrices, for example from interior point optimizations or saddle point problems. Note that in the analysis phase (<i>phase</i> =11) you must provide the numerical values of the matrix A in case of symmetric weighted matching.
<i>iparm</i> [13] output	Number of perturbed pivots. After factorization, contains the number of perturbed pivots for the matrix types: 11, 13, -2, -4 and -6.
<i>iparm</i> [14] output	Peak memory on symbolic factorization. The total peak memory in kilobytes that the solver needs during the analysis and symbolic factorization phase. This value is only computed in phase 1.
<i>iparm</i> [15] output	Permanent memory on symbolic factorization. Permanent memory from the analysis and symbolic factorization phase in kilobytes that the solver needs in the factorization and solve phases. This value is only computed in phase 1.
<i>iparm</i> [16] output	Size of factors/Peak memory on numerical factorization and solution. This parameter provides the size in kilobytes of the total memory consumed by in-core Intel MKL PARDISO for internal floating point arrays. This parameter is computed in phase 1. See <i>iparm</i> [62] for the OOC mode. The total peak memory consumed by Intel MKL PARDISO is $\max(\textit{iparm}[14], \textit{iparm}[15] + \textit{iparm}[16])$
<i>iparm</i> [17] input/output	Report the number of non-zero elements in the factors. <0 Enable reporting if <i>iparm</i> [17] < 0 on entry. The default value is -1. ≥0 Disable reporting.
<i>iparm</i> [18] input/output	Report number of floating point operations (in 10^6 floating point operations) that are necessary to factor the matrix A . <0 Enable report if <i>iparm</i> [18] < 0 on entry. This increases the reordering time.

Component	Description
	≥ 0 * Disable report.
<i>iparm</i> [19] output	Report CG/CGS diagnostics. > 0 CGS succeeded, reports the number of completed iterations. < 0 CG/CGS failed (<i>error</i> = -4 after the solution phase). If <i>phase</i> = 23, then the factors <i>L</i> and <i>U</i> are recomputed for the matrix <i>A</i> and the error flag <i>error</i> = 0 in case of a successful factorization. If <i>phase</i> = 33, then <i>error</i> = -4 signals failure. <i>iparm</i>[19] = - <i>it_cgs</i>*10 - <i>cgs_error</i>. Possible values of <i>cgs_error</i>: 1 - fluctuations of the residuum are too large 2 - $\ dx_{\max_it_cgs/2}\$ is too large (slow convergence) 3 - stopping criterion is not reached at <i>max_it_cgs</i> 4 - perturbed pivots caused iterative refinement 5 - factorization is too fast for this matrix. It is better to use the factorization method with <i>iparm</i>[3] = 0
<i>iparm</i> [20] input	Pivoting for symmetric indefinite matrices. NOTE Use <i>iparm</i>[10] = 1 (scaling) and <i>iparm</i>[12] = 1 (matchings) for highly indefinite symmetric matrices, for example from interior point optimizations or saddle point problems. 0 Apply 1x1 diagonal pivoting during the factorization process. 1* Apply 1x1 and 2x2 Bunch-Kaufman pivoting during the factorization process. Bunch-Kaufman pivoting is available for matrices of <i>mtype</i> = -2, <i>mtype</i> = -4, or <i>mtype</i> = 6. 2 Apply 1x1 diagonal pivoting during the factorization process. Using this value is the same as using <i>iparm</i>[20] = 0 except that the solve step does not automatically make iterative refinements when perturbed pivots are obtained during numerical factorization. The number of iterations is limited to the number of iterative refinements specified by <i>iparm</i>[7] (0 by default). 3 Apply 1x1 and 2x2 Bunch-Kaufman pivoting during the factorization process. Bunch-Kaufman pivoting is available for matrices of <i>mtype</i> = -2, <i>mtype</i> = -4, or <i>mtype</i> = 6. Using this value is the same as using <i>iparm</i>[20] = 1 except that the solve step does not automatically make iterative refinements when perturbed pivots are obtained during numerical factorization. The number of iterations is limited to the number of iterative refinements specified by <i>iparm</i>[7] (0 by default).
<i>iparm</i> [21] output	Inertia: number of positive eigenvalues. Intel MKL PARDISO reports the number of positive eigenvalues for symmetric indefinite matrices.
<i>iparm</i> [22] output	Inertia: number of negative eigenvalues. Intel MKL PARDISO reports the number of negative eigenvalues for symmetric indefinite matrices.

Component	Description
<i>iparm</i> [23] input	Parallel factorization control.
NOTE The two-level factorization algorithm does not improve performance in OOC mode.	
	0* Intel MKL PARDISO uses the classic algorithm for factorization.
	1 Intel MKL PARDISO uses a two-level factorization algorithm. This algorithm generally improves scalability in case of parallel factorization on many OpenMP threads (more than eight).
<i>iparm</i> [24] input	Parallel forward/backward solve control.
	0* Intel MKL PARDISO uses a parallel algorithm for the solve step.
	1 Intel MKL PARDISO uses the sequential forward and backward solve. This feature is available only for in-core Intel MKL PARDISO (see iparm[59]).
<i>iparm</i> [25]	Reserved. Set to zero.
<i>iparm</i> [26] input	Matrix checker.
	0* Intel MKL PARDISO does not check the sparse matrix representation for errors.
	1 Intel MKL PARDISO checks integer arrays <i>ia</i> and <i>ja</i> . In particular, Intel MKL PARDISO checks whether column indices are sorted in increasing order within each row.
<i>iparm</i> [27] input	Single or double precision Intel MKL PARDISO. See iparm[7] for information on controlling the precision of the refinement steps.
Important The <i>iparm</i> [27] value is stored in the Intel MKL PARDISO handle between Intel MKL PARDISO calls, so the precision mode can be changed only during phase 1.	
	0* Input arrays (<i>a</i> , <i>x</i> and <i>b</i>) and all internal arrays must be presented in double precision.
	1 Input arrays (<i>a</i> , <i>x</i> and <i>b</i>) must be presented in single precision. In this case all internal computations are performed in single precision.
<i>iparm</i> [28]	Reserved. Set to zero.
<i>iparm</i> [29] output	Number of zero or negative pivots. If Intel MKL PARDISO detects zero or negative pivot for <i>mtype</i> =2 or <i>mtype</i> =4 matrix types, the factorization is stopped, Intel MKL PARDISO returns immediately with an <i>error</i> = -4, and <i>iparm</i> [29] reports the number of the equation where the first zero or negative pivot is detected.
<i>iparm</i> [30] input	Partial solve and computing selected components of the solution vectors. This parameter controls the solve step of Intel MKL PARDISO. It can be used if only a few components of the solution vectors are needed or if you want to reduce the computation cost at the solve step by utilizing the sparsity of the right-hand sides. To use this option

Component	Description
	the input permutation vector define $perm$ so that when $perm(i) = 1$ it means that either the i-th component in the right-hand sides is nonzero, or the i-th component in the solution vectors is computed, or both, depending on the value of $iparm[30]$. The permutation vector $perm$ must be present in all phases of Intel MKL PARDISO software. At the reordering step, the software overwrites the input vector $perm$ by a permutation vector used by the software at the factorization and solver step. If m is the number of components such that $perm(i) = 1$, then the last m components of the output vector $perm$ are a set of the indices i satisfying the condition $perm(i) = 1$ on input.
	NOTE Turning on this option often increases the time used by Intel MKL PARDISO for factorization and reordering steps, but it can reduce the time required for the solver step.
	Important This feature is only available for in-core Intel MKL PARDISO, so to use it you must set $iparm[59] = 0$. Set the parameters $iparm[7]$ (iterative refinement steps), $iparm[3]$ (preconditioned CGS), $iparm[4]$ (user permutation), and $iparm[35]$ (Schur complement) to 0 as well.
0*	Disables this option.
1	it is assumed that the right-hand sides have only a few non-zero components* and the input permutation vector $perm$ is defined so that $perm(i) = 1$ means that the (i)-th component in the right-hand sides is nonzero. In this case Intel MKL PARDISO only uses the non-zero components of the right-hand side vectors and computes only corresponding components in the solution vectors. That means the i-th component in the solution vectors is only computed if $perm(i) = 1$.
2	It is assumed that the right-hand sides have only a few non-zero components* and the input permutation vector $perm$ is defined so that $perm(i) = 1$ means that the i-th component in the right-hand sides is nonzero. Unlike for $iparm[30]=1$, all components of the solution vector are computed for this setting and all components of the right-hand sides are used. Because all components are used, for $iparm[30]=2$ you must set the i-th component of the right-hand sides to zero explicitly if $perm(i)$ is not equal to 1.
3	Selected components of the solution vectors are computed. The $perm$ array is not related to the right-hand sides and it only indicates which components of the solution vectors should be computed. In this case $perm(i) = 1$ means that the i-th component in the solution vectors is computed.
$iparm[31]$	Reserved. Set to zero.
$iparm[32]$	
$iparm[33]$	Optimal number of OpenMP threads for conditional numerical reproducibility (CNR) mode.
input	Intel MKL PARDISO reads the value of $iparm[33]$ during the analysis phase (phase 1), so you cannot change it later. Because Intel MKL PARDISO uses C random number generator facilities during the analysis phase (phase 1) you must take these precautions to get numerically reproducible results: Do not alter the states of the random number generators.

Component	Description
	Do not run multiple instances of Intel MKL PARDISO in parallel in the analysis phase (phase 1).
	NOTE CNR is only available for the in-core version of Intel MKL PARDISO and the non-parallel version of the nested dissection algorithm. You must also: - set <code>iparm[59]</code> to 0 in order to use the in-core version, - not set <code>iparm[1]</code> to 3 in order to not use the parallel version of the nested dissection algorithm. Otherwise Intel MKL PARDISO does not produce numerically repeatable results even if CNR is enabled for Intel MKL using the functionality described in Support Functions for CNR.
	0* CNR mode for Intel MKL PARDISO is enabled only if it is enabled for Intel MKL using the functionality described in Support Functions for CNR and the in-core version is used. Intel MKL PARDISO determines the optimal number of OpenMP threads automatically, and produces numerically reproducible results regardless of the number of threads.
	>0 CNR mode is enabled for Intel MKL PARDISO if in-core version is used and the optimal number of OpenMP threads for Intel MKL PARDISO to rely on is defined by the value of <code>iparm[33]</code>. You can use <code>iparm[33]</code> to enable CNR mode independent from other Intel MKL domains. To get the best performance, set <code>iparm[33]</code> to the actual number of hardware threads dedicated for Intel MKL PARDISO. Setting <code>iparm[33]</code> to fewer OpenMP threads than the maximum number of them in use reduces the scalability of the problem being solved. Setting <code>iparm[33]</code> to more threads than are available can reduce the performance of Intel MKL PARDISO.
<code>iparm[34]</code>	One- or zero-based indexing of columns and rows.
input	0* One-based indexing: columns and rows indexing in arrays <code>ia</code>, <code>ja</code>, and <code>perm</code> starts from 1 (Fortran-style indexing).
	1 Zero-based indexing: columns and rows indexing in arrays <code>ia</code>, <code>ja</code>, and <code>perm</code> starts from 0 (C-style indexing).
<code>iparm[35]</code>	Schur complement matrix computation control. To calculate this matrix, you must set the input permutation vector <code>perm</code> to a set of indexes such that when $perm(i) = 1$, the i -th element of the initial matrix is an element of the Schur matrix.
input	
	CAUTION You can only set one of <code>iparm[4]</code>, <code>iparm[30]</code>, and <code>iparm[35]</code>, so be sure that the <code>iparm[4]</code> (user permutation) and the <code>iparm[30]</code> (partial solution) parameters are 0 if you set <code>iparm[35]</code>.
	0* Do not compute Schur complement.
	1 Compute Schur complement matrix as part of Intel MKL PARDISO factorization step and return it in the solution vector.
	NOTE This option only computes the Schur complement matrix, and does not calculate factorization arrays.

Component	Description												
	2 Compute Schur complement matrix as part of Intel MKL PARDISO factorization step and return it in the solution vector. Since this option calculates factorization arrays you can use it to launch partial or full solution of the entire problem after the factorization step.												
<i>iparm</i> [36]	Format for matrix storage.												
input	0* Use CSR format (see Three Array Variation of BSR Format) for matrix storage.												
	> 0 Use BSR format (see Three Array Variation of BSR Format) for matrix storage with blocks of size <i>iparm</i> [36].												
NOTE Intel MKL does not support BSR format in these cases: <table> <tr> <td><i>iparm</i>[10] > 0</td><td>Scaling vectors</td></tr> <tr> <td><i>iparm</i>[12] > 0</td><td>Weighted matching</td></tr> <tr> <td><i>iparm</i>[30] > 0</td><td>Partial solution</td></tr> <tr> <td><i>iparm</i>[35] > 0</td><td>Schur complement</td></tr> <tr> <td><i>iparm</i>[55] > 0</td><td>Pivoting control</td></tr> <tr> <td><i>iparm</i>[59] > 0</td><td>OOO Intel MKL PARDISO</td></tr> </table>		<i>iparm</i> [10] > 0	Scaling vectors	<i>iparm</i> [12] > 0	Weighted matching	<i>iparm</i> [30] > 0	Partial solution	<i>iparm</i> [35] > 0	Schur complement	<i>iparm</i> [55] > 0	Pivoting control	<i>iparm</i> [59] > 0	OOO Intel MKL PARDISO
<i>iparm</i> [10] > 0	Scaling vectors												
<i>iparm</i> [12] > 0	Weighted matching												
<i>iparm</i> [30] > 0	Partial solution												
<i>iparm</i> [35] > 0	Schur complement												
<i>iparm</i> [55] > 0	Pivoting control												
<i>iparm</i> [59] > 0	OOO Intel MKL PARDISO												
<i>iparm</i> [37]	Reserved. Set to zero.												
-													
<i>iparm</i> [54]													
<i>iparm</i> [55]	Diagonal and pivoting control.												
	0* Internal function used to work with pivot and calculation of diagonal arrays turned off.												
	1 You can use the mkl_pardiso_pivot callback routine to control pivot elements which appear during numerical factorization. Additionally, you can obtain the elements of initial matrix and factorized matrices after the <code>pardiso</code> factorization step diagonal using the pardiso_getdiag routine. This parameter can be turned on only in the in-core version of Intel MKL PARDISO.												
<i>iparm</i> [56]	Reserved. Set to zero.												
-													
<i>iparm</i> [58]													
<i>iparm</i> [59]	Intel MKL PARDISO mode.												
input	<i>iparm</i>[59] switches between in-core (IC) and out-of-core (OOO) Intel MKL PARDISO. OOO can solve very large problems by holding the matrix factors in files on the disk, which requires a reduced amount of main memory compared to IC. Unless you are operating in sequential mode, you can switch between IC and OOO modes after the reordering phase. However, you can get better Intel MKL PARDISO performance by setting <i>iparm</i>[59] before the reordering phase.												
NOTE The amount of memory used in OOO mode depends on the number of OpenMP threads.													

Component	Description
WARNING Do not increase the number of OpenMP threads used for Intel MKL PARDISO between the first call to <code>pardiso</code> and the factorization or solution phase. Because the minimum amount of memory required for out-of-core execution depends on the number of OpenMP threads, increasing it after the initial call can cause incorrect results.	
0*	IC mode.
1	IC mode is used if the total amount of RAM (in megabytes) needed for storing the matrix factors is less than sum of two values of the environment variables: <code>MKL_PARDISO_OOC_MAX_CORE_SIZE</code> (default value 2000 MB) and <code>MKL_PARDISO_OOC_MAX_SWAP_SIZE</code> (default value 0 MB); otherwise OOC mode is used. In this case amount of RAM used by OOC mode cannot exceed the value of <code>MKL_PARDISO_OOC_MAX_CORE_SIZE</code>. If the total peak memory needed for storing the local arrays is more than <code>MKL_PARDISO_OOC_MAX_CORE_SIZE</code>, increase <code>MKL_PARDISO_OOC_MAX_CORE_SIZE</code> if possible. NOTE Conditional numerical reproducibility (CNR) is not supported for this mode.
2	OOC mode. The OOC mode can solve very large problems by holding the matrix factors in files on the disk. Hence the amount of RAM required by OOC mode is significantly reduced compared to IC mode. If the total peak memory needed for storing the local arrays is more than <code>MKL_PARDISO_OOC_MAX_CORE_SIZE</code>, increase <code>MKL_PARDISO_OOC_MAX_CORE_SIZE</code> if possible. To obtain better Intel MKL PARDISO performance, during the numerical factorization phase you can provide the maximum number of right-hand sides, which can be used further during the solving phase.
<code>iparm[60]</code> -	Reserved. Set to zero.
<code>iparm[61]</code>	
<code>iparm[62]</code> output	Size of the minimum OOC memory for numerical factorization and solution. This parameter provides the size in kilobytes of the minimum memory required by OOC Intel MKL PARDISO for internal floating point arrays. This parameter is computed in phase 1. Total peak memory consumption of OOC Intel MKL PARDISO can be estimated as $\max(iparm[14], iparm[15] + iparm[62])$.
<code>iparm[63]</code>	Reserved. Set to zero.

NOTE

Generally in sparse matrices, components which are equal to zero can be considered non-zero if necessary. For example, in order to make a matrix structurally symmetric, elements which are zero can be considered non-zero. See [Sparse Matrix Storage Formats](#) for an example.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. PARDISO_DATA_TYPE

The following table lists the values of `PARDISO_DATA_TYPE` depending on the matrix types and values of the parameter `iparm[27]`.

Data type value	Matrix type <i>mtype</i>	<i>iparm</i> [27]	comments
double	1, 2, -2, 11	0	Real matrices, double precision
float		1	Real matrices, single precision
MKL_Complex16	3, 6, 13, 4, -4	0	Complex matrices, double precision
MKL_Complex8		1	Complex matrices, single precision

Parallel Direct Sparse Solver for Clusters Interface

The Parallel Direct Sparse Solver for Clusters Interface solves large linear systems of equations with sparse matrices on clusters. It is

- high performing
- robust
- memory efficient
- easy to use

A hybrid implementation combines Message Passing Interface (MPI) technology for data exchange between parallel tasks (processes) running on different nodes, and OpenMP* technology for parallelism inside each node of the cluster. This approach effectively uses modern hardware resources such as clusters consisting of nodes with multi-core processors. The solver code is optimized for the latest Intel processors, but also performs well on clusters consisting of non-Intel processors.

Code examples are available in the Intel MKL installation `examples` directory.

Optimization Notice

Notice revision #20110804

Parallel Direct Sparse Solver for Clusters Interface Algorithm

Parallel Direct Sparse Solver for Clusters Interface solves a set of sparse linear equations

$$A * X = B$$

with multiple right-hand sides using a distributed LU , LL^T , LDL^T or LDL^* factorization, where A is an n -by- n matrix, and X and B are n -by- $nrhs$ matrices.

The solution comprises four tasks:

- analysis and symbolic factorization;
- numerical factorization;
- forward and backward substitution including iterative refinement;
- termination to release all internal solver memory.

The solver first computes a symmetric fill-in reducing permutation P based on the nested dissection algorithm from the METIS package [Karypis98] (included with Intel MKL), followed by the Cholesky or other type of factorization (depending on matrix type) [Schenk00-2] of PAP^T . The solver uses either diagonal pivoting, or 1x1 and 2x2 Bunch and Kaufman pivoting for symmetric indefinite or Hermitian matrices before finding an approximation of X by forward and backward substitution and iterative refinement.

The initial matrix A is perturbed whenever numerically acceptable 1x1 and 2x2 pivots cannot be found within the diagonal blocks. One or two passes of iterative refinement may be required to correct the effect of the perturbations. This restricted notion of pivoting with iterative refinement is effective for highly indefinite symmetric systems. For a large set of matrices from different application areas, the accuracy of this method is comparable to a direct factorization method that uses complete sparse pivoting techniques [Schenk04].

Parallel Direct Sparse Solver for Clusters additionally improves the pivoting accuracy by applying symmetric weighted matching algorithms. These methods identify large entries in the coefficient matrix A that, if permuted close to the diagonal, enable the factorization process to identify more acceptable pivots and proceed with fewer pivot perturbations. The methods are based on maximum weighted matching and improve the quality of the factor in a complementary way to the alternative idea of using more complete pivoting techniques.

Parallel Direct Sparse Solver for Clusters Interface Matrix Storage

The sparse data storage in the Parallel Direct Sparse Solver for Clusters Interface follows the scheme described in the [Sparse Matrix Storage Formats](#) section using the variable ja for *columns*, ia for *rowIndex*, and a for *values*. Column indices ja must be in increasing order per row and each diagonal element to be present in the matrix structure (even if it is zero).

When an input data structure is not accessed in a call, a NULL pointer or any valid address can be passed as a placeholder for that argument.

Algorithm Parallelization and Data Distribution

Intel® MKL Parallel Direct Sparse Solver for Clusters enables parallel execution of the solution algorithm with efficient data distribution.

The master MPI process performs the symbolic factorization phase to represent matrix A as computational tree. Then matrix A is divided among all MPI processes in a one-dimensional manner. The same distribution is used for L -factor (the lower triangular matrix in Cholesky decomposition). Matrix A and all required internal data are broadcast to slave MPI processes. Each MPI process fills in its own parts of L -factor with initial values of the matrix A .

Parallel Direct Sparse Solver for Clusters Interface computes all independent parts of L -factor completely in parallel. When a block of the factor must be updated by other blocks, these updates are independently passed to a temporary array on each updating MPI process. It further gathers the result into an updated

block using the `MPI_Reduce()` routine. The computations within an MPI process are dynamically divided among OpenMP threads using pipelining parallelism with a combination of left- and right-looking techniques similar to those of the PARDISO* software. Level 3 BLAS operations from Intel MKL ensure highly efficient performance of block-to-block update operations.

During forward/backward substitutions, respective Right Hand Side (RHS) parts are distributed among all MPI processes. All these processes participate in the computation of the solution. Finally, the solution is gathered on the master MPI process.

This approach demonstrates good scalability on clusters with Infiniband* technology. Another advantage of the approach is the effective distribution of *L-factor* among cluster nodes. This enables the solution of tasks with a much higher number of non-zero elements than it is possible with any Symmetric Multiprocessing (SMP) in-core direct solver.

The algorithm ensures that the memory required to keep internal data on each MPI process is decreased when the number of MPI processes in a run increases. However, the solver requires that matrix *A* and some other internal arrays completely fit into the memory of each MPI process.

To get the best performance, run one MPI process per physical node and set the number of OpenMP* threads per node equal to the number of physical cores on the node.

NOTE

Instead of calling `MPI_Init()`, initialize MPI with `MPI_Init_thread()` and set the MPI threading level to `MPI_THREAD_FUNNELED` or higher. For details, see the code examples in `<install_dir>/examples`.

cluster_sparse_solver

Calculates the solution of a set of sparse linear equations with single or multiple right-hand sides.

Syntax

```
void cluster_sparse_solver (_MKL_DSS_HANDLE_t pt, const MKL_INT *maxfct, const MKL_INT *mnum, const MKL_INT *mtype, const MKL_INT *phase, const MKL_INT *n, const void *a, const MKL_INT *ia, const MKL_INT *ja, MKL_INT *perm, const MKL_INT *nrhs, MKL_INT *iparm, const MKL_INT *msglvl, void *b, void *x, const int *comm, MKL_INT *error);
```

Include Files

- `mkl_cluster_sparse_solver.h`

Description

The routine `cluster_sparse_solver` calculates the solution of a set of sparse linear equations

$$A \cdot X = B$$

with single or multiple right-hand sides, using a parallel *LU*, *LDL*, or *LL^T* factorization, where *A* is an *n*-by-*n* matrix, and *X* and *B* are *n*-by-*nrhs* vectors or matrices.

Input Parameters

NOTE

Most of the input parameters (except for the *pt*, *phase*, and *comm* parameters and, for the distributed format, the *a*, *ia*, and *ja* arrays) must be set on the master MPI process only, and ignored on other processes. Other MPI processes get all required data from the master MPI process using the MPI communicator, *comm*.

pt Array of size 64.
Handle to internal data structure. The entries must be set to zero before the first call to `cluster_sparse_solver`.

CAUTION
After the first call to `cluster_sparse_solver` do not modify *pt*, as that could cause a serious memory leak.

maxfct Ignored; assumed equal to 1.

mnum Ignored; assumed equal to 1.

mtype Defines the matrix type, which influences the pivoting method. The Parallel Direct Sparse Solver for Clusters solver supports the following matrices:

1	real and structurally symmetric
2	real and symmetric positive definite
-2	real and symmetric indefinite
3	complex and structurally symmetric
4	complex and Hermitian positive definite
-4	complex and Hermitian indefinite
6	complex and symmetric
11	real and nonsymmetric
13	complex and nonsymmetric

phase Controls the execution of the solver. Usually it is a two- or three-digit integer. The first digit indicates the starting phase of execution and the second digit indicates the ending phase. Parallel Direct Sparse Solver for Clusters has the following phases of execution:

- Phase 1: Fill-reduction analysis and symbolic factorization
- Phase 2: Numerical factorization
- Phase 3: Forward and Backward solve including optional iterative refinement
- Memory release (*phase*= -1)

If a previous call to the routine has computed information from previous phases, execution may start at any phase. The *phase* parameter can have the following values:

<i>phase</i>	Solver Execution Steps
11	Analysis
12	Analysis, numerical factorization

<i>phase</i>	Solver Execution Steps
13	Analysis, numerical factorization, solve, iterative refinement
22	Numerical factorization
23	Numerical factorization, solve, iterative refinement
33	Solve, iterative refinement
-1	Release all internal memory for all matrices

n Number of equations in the sparse linear systems of equations $A^*X = B$.
Constraint: $n > 0$.

a Array. Contains the non-zero elements of the coefficient matrix A corresponding to the indices in *ja*. The coefficient matrix can be either real or complex. The matrix must be stored in the three-array variant of the compressed sparse row (CSR3) or in the three-array variant of the block compressed sparse row (BSR3) format, and the matrix must be stored with increasing values of *ja* for each row.

For CSR3 format, the size of *a* is the same as that of *ja*. Refer to the *values* array description in [Three Array Variation of CSR Format](#) for more details.

For BSR3 format the size of *a* is the size of *ja* multiplied by the square of the block size. Refer to the *values* array description in [Three Array Variation of BSR Format](#) for more details.

NOTE

For centralized input (*iparm*[39]=0), provide the *a* array for the master MPI process only. For distributed assembled input (*iparm*[39]=1 or *iparm*[39]=2), provide it for all MPI processes.

Important

The column indices of non-zero elements of each row of the matrix A must be stored in increasing order, and the diagonal elements must be available and stored in the array, even if they are zero.

ia For CSR3 format, *ia*[*i*] ($i < n$) points to the first column index of row *i* in the array *ja*. That is, *ia*[*i*] gives the index of the element in array *a* that contains the first non-zero element from row *i* of A . The last element *ia*[*n*] is taken to be equal to the number of non-zero elements in A , plus one. Refer to *rowIndex* array description in [Three Array Variation of CSR Format](#) for more details.

For BSR3 format, *ia*[*i*] ($i < n$) points to the first column index of row *i* in the array *ja*. That is, *ia*[*i*] gives the index of the element in array *a* that contains the first non-zero block from row *i* of A . The last element *ia*[*n*] is taken to be equal to the number of non-zero blocks in A , plus one. Refer to *rowIndex* array description in [Three Array Variation of BSR Format](#) for more details.

The array *ia* is accessed in all phases of the solution process.

Indexing of *ia* is one-based by default, but it can be changed to zero-based by setting the appropriate value to the parameter *iparm*[34]. For zero-based indexing, the last element *ia*[*n*] is assumed to be equal to the number of non-zero elements in matrix *A*.

NOTE

For centralized input (*iparm*[39]=0), provide the *ia* array at the master MPI process only. For distributed assembled input (*iparm*[39]=1 or *iparm*[39]=2), provide it at all MPI processes.

ja

For CSR3 format, array *ja* contains column indices of the sparse matrix *A*. It is important that the indices are in increasing order per row. For structurally symmetric matrices it is assumed that all diagonal elements are stored (even if they are zeros) in the list of non-zero elements in *a* and *ja*. For symmetric matrices, the solver needs only the upper triangular part of the system as is shown for *columns* array in [Three Array Variation of CSR Format](#).

For BSR3 format, array *ja* contains column indices of the sparse matrix *A*. It is important that the indices are in increasing order per row. For structurally symmetric matrices it is assumed that all diagonal blocks are stored (even if they are zeros) in the list of non-zero blocks in *a* and *ja*. For symmetric matrices, the solver needs only the upper triangular part of the system as is shown for *columns* array in [Three Array Variation of BSR Format](#).

The array *ja* is accessed in all phases of the solution process.

Indexing of *ja* is one-based by default, but it can be changed to zero-based by setting the appropriate value to the parameter *iparm*(35).

NOTE

For centralized input (*iparm*(40)=0), provide the *ja* array at the master MPI process only. For distributed assembled input (*iparm*(40)=1 or *iparm*(40)=2), provide it at all MPI processes.

perm

Ignored.

nrhs

Number of right-hand sides that need to be solved for.

iparm

Array, size 64. This array is used to pass various parameters to Parallel Direct Sparse Solver for Clusters Interface and to return some useful information after execution of the solver.

See [cluster_sparse_solver iparm Parameter](#) for more details about the *iparm* parameters.

msglvl

Message level information. If *msglvl* = 0 then *cluster_sparse_solver* generates no output, if *msglvl* = 1 the solver prints statistical information to the screen.

Statistics include information such as the number of non-zero elements in *L-factor* and the timing for each phase.

Set `msglvl = 1` if you report a problem with the solver, since the additional information provided can facilitate a solution.

b Array, size $n \times nrhs$. On entry, contains the right-hand side vector/matrix *B*, which is placed in memory contiguously. The `b[i+k*n]` must hold the *i*-th component of *k*-th right-hand side vector. Note that *b* is only accessed in the solution phase.

comm MPI communicator. The solver uses the Fortran MPI communicator internally. Convert the MPI communicator to Fortran using the `MPI_Comm_c2f()` function. See the examples in the `<install_dir>/examples` directory.

Output Parameters

pt Handle to internal data structure.

perm Ignored.

iparm On output, some *iparm* values report information such as the numbers of non-zero elements in the factors.

See [cluster_sparse_solver iparm Parameter](#) for more details about the *iparm* parameters.

b On output, the array is replaced with the solution if `iparm[5] = 1`.

x Array, size $(n \times nrhs)$. If `iparm[5]=0` it contains solution vector/matrix *X*, which is placed contiguously in memory. The `x[i+k*n]` element must hold the *i*-th component of the *k*-th solution vector. Note that *x* is only accessed in the solution phase.

error The error indicator according to the below table:

error	Information
0	no error
-1	input inconsistent
-2	not enough memory
-3	reordering problem
-5	unclassified (internal) error

cluster_sparse_solver iparm Parameter

The following table describes all individual components of the Parallel Direct Sparse Solver for Clusters Interface *iparm* parameter. Components which are not used must be initialized with 0. Default values are denoted with an asterisk (*).

Component	Description
<i>iparm</i> [0]	Use default values.
0	<i>iparm</i> [1] - <i>iparm</i> (64) are filled with default values.

Component	Description
input	$!=0$ You must supply all values in components $iparm[1] - iparm(64)$.
$iparm[1]$	Fill-in reducing ordering for the input matrix.
input	2* The nested dissection algorithm from the METIS package [Karypis98].
	3 The parallel version of the nested dissection algorithm. It can decrease the time of computations on multi-core computers, especially when Phase 1 takes significant time.
$iparm[2]$	Reserved. Set to zero.
$iparm[5]$	Write solution on x .
input	NOTE The array x is always used.
	0* The array x contains the solution; right-hand side vector b is kept unchanged.
	1 The solver stores the solution on the right-hand side b .
$iparm[6]$	Number of iterative refinement steps performed.
output	Reports the number of iterative refinement steps that were actually performed during the solve step.
$iparm[7]$	Iterative refinement step.
input	On entry to the solve and iterative refinement step, $iparm[7]$ must be set to the maximum number of iterative refinement steps that the solver performs.
	0* The solver automatically performs two steps of iterative refinement when perturbed pivots are obtained during the numerical factorization.
	>0 Maximum number of iterative refinement steps that the solver performs. The solver performs not more than the absolute value of $iparm[7]$ steps of iterative refinement. The solver might stop the process before the maximum number of steps if - a satisfactory level of accuracy of the solution in terms of backward error is achieved, - or if it determines that the required accuracy cannot be reached. In this case Parallel Direct Sparse Solver for Clusters Interface returns -4 in the <i>error</i> parameter. The number of executed iterations is reported in $iparm[6]$.
	<0 Same as above, but the accumulation of the residuum uses extended precision real and complex data types. Perturbed pivots result in iterative refinement (independent of $iparm[7]=0$) and the number of executed iterations is reported in $iparm[6]$.
$iparm[8]$	Reserved. Set to zero.
$iparm[9]$	Pivoting perturbation.
input	This parameter instructs Parallel Direct Sparse Solver for Clusters Interface how to handle small pivots or zero pivots for nonsymmetric matrices ($mtype = 11$ or $mtype = 13$) and symmetric matrices ($mtype = -2$, $mtype = -4$, or $mtype = 6$). For these matrices the solver uses a complete supernode pivoting approach. When the factorization algorithm reaches a point where it cannot factor the supernodes with this pivoting strategy, it uses a pivoting perturbation strategy similar to [Li99], [Schenk04]. Small pivots are perturbed with $eps = 10^{-iparm[9]}$.

Component	Description
	The magnitude of the potential pivot is tested against a constant threshold of $\alpha = \text{eps} * A2 _{\text{inf}},$ where $\text{eps} = 10^{(-\text{iparm}[9])}$, $A2 = P * P_{\text{MPS}} * D_r * A * D_c * P$, and $A2 _{\text{inf}}$ is the infinity norm of the scaled and permuted matrix A. Any tiny pivots encountered during elimination are set to the sign $(l_{\text{II}}) * \text{eps} * A2 _{\text{inf}}$, which trades off some numerical stability for the ability to keep pivots from getting too small. Small pivots are therefore perturbed with $\text{eps} = 10^{(-\text{iparm}[9])}$.
13*	The default value for nonsymmetric matrices ($\text{mtype}=11$, $\text{mtype}=13$), $\text{eps} = 10^{-13}$.
8*	The default value for symmetric indefinite matrices ($\text{mtype}=-2$, $\text{mtype}=-4$, $\text{mtype}=6$), $\text{eps} = 10^{-8}$.
<i>iparm</i> [10] input	Scaling vectors. Parallel Direct Sparse Solver for Clusters Interface uses a maximum weight matching algorithm to permute large elements on the diagonal and to scale. Use <i>iparm</i>[10] = 1 (scaling) and <i>iparm</i>[12] = 1 (matching) for highly indefinite symmetric matrices, for example, from interior point optimizations or saddle point problems. Note that in the analysis phase (<i>phase</i>=11) you must provide the numerical values of the matrix A in array a in case of scaling and symmetric weighted matching.
0*	Disable scaling. Default for symmetric indefinite matrices.
1*	Enable scaling. Default for nonsymmetric matrices. Scale the matrix so that the diagonal elements are equal to 1 and the absolute values of the off-diagonal entries are less or equal to 1. This scaling method is applied to nonsymmetric matrices ($\text{mtype} = 11$, $\text{mtype} = 13$). The scaling can also be used for symmetric indefinite matrices ($\text{mtype} = -2$, $\text{mtype} = -4$, $\text{mtype} = 6$) when the symmetric weighted matchings are applied (<i>iparm</i>[12] = 1). Note that in the analysis phase (<i>phase</i>=11) you must provide the numerical values of the matrix A in case of scaling.
<i>iparm</i> [11]	Reserved. Set to zero.
<i>iparm</i> [12] input	Improved accuracy using (non-) symmetric weighted matching. Parallel Direct Sparse Solver for Clusters Interface can use a maximum weighted matching algorithm to permute large elements close the diagonal. This strategy adds an additional level of reliability to the factorization methods and complements the alternative of using more complete pivoting techniques during the numerical factorization.
0*	Disable matching. Default for symmetric indefinite matrices.
1*	Enable matching. Default for nonsymmetric matrices. Maximum weighted matching algorithm to permute large elements close to the diagonal. It is recommended to use <i>iparm</i>[10] = 1 (scaling) and <i>iparm</i>[12] = 1 (matching) for highly indefinite symmetric matrices, for example from interior point optimizations or saddle point problems. Note that in the analysis phase (<i>phase</i>=11) you must provide the numerical values of the matrix A in case of symmetric weighted matching.

Component	Description
<i>iparm</i> [13] -	Reserved. Set to zero.
<i>iparm</i> [19]	
<i>iparm</i> [20]	Pivoting for symmetric indefinite matrices.
input	0 Apply 1x1 diagonal pivoting during the factorization process.
	1* Apply 1x1 and 2x2 Bunch-Kaufman pivoting during the factorization process. Bunch-Kaufman pivoting is available for matrices of <i>mt</i> <i>type</i> =-2, <i>mt</i> <i>type</i> =-4, or <i>mt</i> <i>type</i> =6.
<i>iparm</i> [21] -	Reserved. Set to zero.
<i>iparm</i> [25]	
<i>iparm</i> [26]	Matrix checker.
input	0* Do not check the sparse matrix representation for errors.
	1 Check integer arrays <i>ia</i> and <i>ja</i> . In particular, check whether the column indices are sorted in increasing order within each row.
<i>iparm</i> [27]	Single or double precision Parallel Direct Sparse Solver for Clusters Interface.
input	See iparm[7] for information on controlling the precision of the refinement steps.
	0* Input arrays (<i>a</i> , <i>x</i> and <i>b</i>) and all internal arrays must be presented in double precision.
	1 Input arrays (<i>a</i> , <i>x</i> and <i>b</i>) must be presented in single precision. In this case all internal computations are performed in single precision.
<i>iparm</i> [28] -	Reserved. Set to zero.
<i>iparm</i> [33]	
<i>iparm</i> [34]	One- or zero-based indexing of columns and rows.
input	0* One-based indexing: columns and rows indexing in arrays <i>ia</i> , <i>ja</i> , and <i>perm</i> starts from 1 (Fortran-style indexing).
	1 Zero-based indexing: columns and rows indexing in arrays <i>ia</i> , <i>ja</i> , and <i>perm</i> starts from 0 (C-style indexing).
<i>iparm</i> [36]	Format for matrix storage.
input	0* Use CSR format (see Three Array Variation of BSR Format) for matrix storage.
	> 0 Use BSR format (see Three Array Variation of BSR Format) for matrix storage with blocks of size <i>iparm</i> [36].

NOTE

Intel MKL does not support BSR format in these cases:

- iparm*[10] > 0 Scaling vectors
- iparm*[12] > 0 Weighted matching
- iparm*[30] > 0 Partial solution
- iparm*[35] > 0 Schur complement

<code>iparm[42]</code> -	Reserved. Set to zero.								
<code>iparm[63]</code> input									

NOTE

Generally in sparse matrices, components which are equal to zero can be considered non-zero if necessary. For example, in order to make a matrix structurally symmetric, elements which are zero can be considered non-zero. See [Sparse Matrix Storage Formats](#) for an example.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Direct Sparse Solver (DSS) Interface Routines

Intel MKL supports the DSS interface, an alternative to the Intel MKL PARDISO interface for the direct sparse solver. The DSS interface implements a group of user-callable routines that are used in the step-by-step solving process and utilizes the general scheme described in [Appendix A Linear Solvers Basics](#) for solving sparse systems of linear equations. This interface also includes one routine for gathering statistics related to the solving process.

The DSS interface also supports the out-of-core (OOC) mode.

Table "DSS Interface Routines" lists the names of the routines and describes their general use.

DSS Interface Routines

Routine	Description
<code>dss_create</code>	Initializes the solver and creates the basic data structures necessary for the solver. This routine must be called before any other DSS routine.
<code>dss_define_structure</code>	Informs the solver of the locations of the non-zero elements of the matrix.
<code>dss_reorder</code>	Based on the non-zero structure of the matrix, computes a permutation vector to reduce fill-in during the factoring process.
<code>dss_factor_real</code> , <code>dss_factor_complex</code>	Computes the LU , LDL^T or LL^T factorization of a real or complex matrix.
<code>dss_solve_real</code> , <code>dss_solve_complex</code>	Computes the solution vector for a system of equations based on the factorization computed in the previous phase.
<code>dss_delete</code>	Deletes all data structures created during the solving process.
<code>dss_statistics</code>	Returns statistics about various phases of the solving process.

To find a single solution vector for a single system of equations with a single right-hand side, invoke the Intel MKL DSS interface routines in this order:

1. `dss_create`
2. `dss_define_structure`

3. `dss_reorder`
4. `dss_factor_real`, `dss_factor_complex`
5. `dss_solve_real`, `dss_solve_complex`
6. `dss_delete`

However, in certain applications it is necessary to produce solution vectors for multiple right-hand sides for a given factorization and/or factor several matrices with the same non-zero structure. Consequently, it is sometimes necessary to invoke the Intel MKL sparse routines in an order other than that listed, which is possible using the DSS interface. The solving process is conceptually divided into six phases. [Figure "Typical order for invoking DSS interface routines"](#) indicates the typical order in which the DSS interface routines can be invoked.

Typical order for invoking DSS interface routines

See the code examples that use the DSS interface routines to solve systems of linear equations in the Intel MKL installation directory (`dss_*.c`).

- `examples/solverc/source`

DSS Interface Description

Each DSS routine reads from or writes to a data object called a *handle*. Refer to [Memory Allocation and Handles](#) to determine the correct method for declaring a handle argument for each language. For simplicity, the descriptions in DSS routines refer to the data type as `MKL_DSS_HANDLE`.

Routine Options

The DSS routines have an integer argument (referred below to as *opt*) for passing various options to the routines. The permissible values for *opt* should be specified using only the symbol constants defined in the language-specific header files (see [Implementation Details](#)). The routines accept options for setting the

message and termination levels as described in [Table "Symbolic Names for the Message and Termination Levels Options"](#). Additionally, each routine accepts the option `MKL_DSS_DEFAULTS` that sets the default values (as documented) for *opt* to the routine.

Symbolic Names for the Message and Termination Levels Options

Message Level	Termination Level
<code>MKL_DSS_MSG_LVL_SUCCESS</code>	<code>MKL_DSS_TERM_LVL_SUCCESS</code>
<code>MKL_DSS_MSG_LVL_INFO</code>	<code>MKL_DSS_TERM_LVL_INFO</code>
<code>MKL_DSS_MSG_LVL_WARNING</code>	<code>MKL_DSS_TERM_LVL_WARNING</code>
<code>MKL_DSS_MSG_LVL_ERROR</code>	<code>MKL_DSS_TERM_LVL_ERROR</code>
<code>MKL_DSS_MSG_LVL_FATAL</code>	<code>MKL_DSS_TERM_LVL_FATAL</code>

The settings for message and termination levels can be set on any call to a DSS routine. However, once set to a particular level, they remain at that level until they are changed in another call to a DSS routine.

You can specify both message and termination level for a DSS routine by adding the options together. For example, to set the message level to `debug` and the termination level to `error` for all the DSS routines, use the following call:

```
dss_create( handle, MKL_DSS_MSG_LVL_INFO + MKL_DSS_TERM_LVL_ERROR)
```

User Data Arrays

Many of the DSS routines take arrays of user data as input. For example, pointers to user arrays are passed to the routine `dss_define_structure` to describe the location of the non-zero entries in the matrix.

CAUTION

Do not modify the contents of these arrays after they are passed to one of the solver routines.

DSS Implementation Details

To promote portability across platforms and ease of use across different languages, use the appropriate Intel MKL DSS header file:

- `mkl_dss.h`

The header file defines symbolic constants for returned error values, function options, certain defined data types, and function prototypes.

NOTE

Constants for options, returned error values, and message severities must be referred only by the symbolic names that are defined in these header files. Use of the Intel MKL DSS software without including one of the above header files is not supported.

Memory Allocation and Handles

You do not need to allocate any temporary working storage in order to use the Intel MKL DSS routines, because the solver itself allocates any required storage. To enable multiple users to access the solver simultaneously, the solver keeps track of the storage allocated for a particular application by using a *handle* data object.

Each of the Intel MKL DSS routines creates, uses, or deletes a handle. Consequently, any program calling an Intel MKL DSS routine must be able to allocate storage for a handle. The exact syntax for allocating storage for a handle varies from language to language. To standardize the handle declarations, the language-specific header files declare constants and defined data types that must be used when declaring a handle object in your code.

```
#include "mkl_dss.h"
_MKL_DSS_HANDLE_t handle;
```

In addition to the definition for the correct declaration of a handle, the include file also defines the following:

- function prototypes for languages that support prototypes
- symbolic constants that are used for the returned error values
- user options for the solver routines
- constants indicating message severity.

DSS Routines

dss_create

Initializes the solver.

Syntax

```
MKL_INT dss_create(_MKL_DSS_HANDLE_t *handle, MKL_INT const *opt)
```

Include Files

- mkl.h

Description

The `dss_create` routine initializes the solver. After the call to `dss_create`, all subsequent invocations of the Intel MKL DSS routines must use the value of the handle returned by `dss_create`.

WARNING

Do not write the value of handle directly.

The default value of the parameter `opt` is

```
MKL_DSS_MSG_LVL_WARNING + MKL_DSS_TERM_LVL_ERROR.
```

By default, the DSS routines use double precision for solving systems of linear equations. The precision used by the DSS routines can be set to single mode by adding the following value to the `opt` parameter:

```
MKL_DSS_SINGLE_PRECISION.
```

Input data and internal arrays are required to have single precision.

By default, the DSS routines use Fortran style (one-based) indexing for input arrays of integer types (the first value is referenced as array element 1). To set indexing to C style (the first value is referenced as array element 0), add the following value to the `opt` parameter:

```
MKL_DSS_ZERO_BASED_INDEXING.
```

The `opt` parameter can also control number of refinement steps used on the solution stage by specifying the two following values:

`MKL_DSS_REFINEMENT_OFF` - maximum number of refinement steps is set to zero;

`MKL_DSS_REFINEMENT_ON` (default value) - maximum number of refinement steps is set to 2.

By default, DSS uses in-core computations. To launch the out-of-core version of DSS (OOC DSS) you can add to this parameter one of two possible values: `MKL_DSS_OOC_STRONG` and `MKL_DSS_OOC_VARIABLE`.

`MKL_DSS_OOC_STRONG` - OOC DSS is used.

`MKL_DSS_OOC_VARIABLE` - if the memory needed for the matrix factors is less than the value of the environment variable `MKL_PARDISO_OOC_MAX_CORE_SIZE`, then the OOC DSS uses the in-core kernels of Intel MKL PARDISO, otherwise it uses the OOC computations.

The variable `MKL_PARDISO_OOC_MAX_CORE_SIZE` defines the maximum size of RAM allowed for storing work arrays associated with the matrix factors. It is ignored if `MKL_DSS_OOC_STRONG` is set. The default value of `MKL_PARDISO_OOC_MAX_CORE_SIZE` is 2000 MB. This value and default path and file name for storing temporary data can be changed using the configuration file `pardiso_ooc.cfg` or command line (See more details in the description of the [pardiso](#) routine).

WARNING

Other than message and termination level options, do not change the OOC DSS settings after they are specified in the routine `dss_create`.

Input Parameters

opt

Parameter to pass the DSS options. The default value is `MKL_DSS_MSG_LVL_WARNING + MKL_DSS_TERM_LVL_ERROR`.

Output Parameters

handle

Pointer to the data structure storing internal DSS results (`MKL_DSS_HANDLE`).

Return Values

`MKL_DSS_SUCCESS`

`MKL_DSS_INVALID_OPTION`

`MKL_DSS_OUT_OF_MEMORY`

`MKL_DSS_MSG_LVL_ERR`

`MKL_DSS_TERM_LVL_ERR`

`dss_define_structure`

Communicates locations of non-zero elements in the matrix to the solver.

Syntax

```
MKL_INT dss_define_structure(_MKL_DSS_HANDLE_t *handle, MKL_INT const *opt, MKL_INT
const *rowIndex, MKL_INT const *nRows, MKL_INT const *nCols, MKL_INT const *columns,
MKL_INT const *nNonZeros);
```

Include Files

- `mkl.h`

Description

The routine `dss_define_structure` communicates the locations of the *nNonZeros* number of non-zero elements in a matrix of *nRows* * *nCols* size to the solver.

NOTE

The Intel MKL DSS software operates only on square matrices, so *nRows* must be equal to *nCols*.

To communicate the locations of non-zero elements in the matrix, do the following:

1. Define the general non-zero structure of the matrix by specifying the value for the options argument *opt*. You can set the following values for real matrices:

- MKL_DSS_SYMMETRIC_STRUCTURE
- MKL_DSS_SYMMETRIC
- MKL_DSS_NON_SYMMETRIC

and for complex matrices:

- MKL_DSS_SYMMETRIC_STRUCTURE_COMPLEX
- MKL_DSS_SYMMETRIC_COMPLEX
- MKL_DSS_NON_SYMMETRIC_COMPLEX

The information about the matrix type must be defined in `dss_define_structure`.

2. Provide the actual locations of the non-zeros by means of the arrays *rowIndex* and *columns* (see [Sparse Matrix Storage Format](#)).

Input Parameters

<i>opt</i>	Parameter to pass the DSS options. The default value for the matrix structure is MKL_DSS_SYMMETRIC.
<i>rowIndex</i>	Array of size <i>nRows</i> +1. Defines the location of non-zero entries in the matrix.
<i>nRows</i>	Number of rows in the matrix.
<i>nCols</i>	Number of columns in the matrix; must be equal to <i>nRows</i> .
<i>columns</i>	Array of size <i>nNonZeros</i> . Defines the column location of non-zero entries in the matrix.
<i>nNonZeros</i>	Number of non-zero elements in the matrix.

Output Parameters

<i>handle</i>	Pointer to the data structure storing internal DSS results (MKL_DSS_HANDLE).

Return Values

MKL_DSS_SUCCESS
 MKL_DSS_STATE_ERR
 MKL_DSS_INVALID_OPTION
 MKL_DSS_STRUCTURE_ERR
 MKL_DSS_ROW_ERR
 MKL_DSS_COL_ERR
 MKL_DSS_NOT_SQUARE
 MKL_DSS_TOO_FEW_VALUES

MKL_DSS_TOO_MANY_VALUES

MKL_DSS_OUT_OF_MEMORY

MKL_DSS_MSG_LVL_ERR

MKL_DSS_TERM_LVL_ERR

dss_reorder

Computes or sets a permutation vector that minimizes the fill-in during the factorization phase.

Syntax

```
MKL_INT dss_reorder(_MKL_DSS_HANDLE_t *handle, MKL_INT const *opt, MKL_INT const *perm)
```

Include Files

- mkl.h

Description

If *opt* contains the option MKL_DSS_AUTO_ORDER, then the routine `dss_reorder` computes a permutation vector that minimizes the fill-in during the factorization phase. For this option, the routine ignores the contents of the *perm* array.

If *opt* contains the option MKL_DSS_METIS_OPENMP_ORDER, then the routine `dss_reorder` computes permutation vector using the parallel nested dissections algorithm to minimize the fill-in during the factorization phase. This option can be used to decrease the time of `dss_reorder` call on multi-core computers. For this option, the routine ignores the contents of the *perm* array.

If *opt* contains the option MKL_DSS_MY_ORDER, then you must supply a permutation vector in the array *perm*. In this case, the array *perm* is of length *nRows*, where *nRows* is the number of rows in the matrix as defined by the previous call to `dss_define_structure`.

If *opt* contains the option MKL_DSS_GET_ORDER, then the permutation vector computed during the `dss_reorder` call is copied to the array *perm*. In this case you must allocate the array *perm* beforehand. The permutation vector is computed in the same way as if the option MKL_DSS_AUTO_ORDER is set.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Input Parameters

<i>opt</i>	Parameter to pass the DSS options. The default value for the permutation type is MKL_DSS_AUTO_ORDER.
<i>perm</i>	Array of length <i>nRows</i> . Contains a user-defined permutation vector (accessed only if <i>opt</i> contains MKL_DSS_MY_ORDER or MKL_DSS_GET_ORDER).

Output Parameters

handle Pointer to the data structure storing internal DSS results (MKL_DSS_HANDLE).

Return Values

MKL_DSS_SUCCESS
 MKL_DSS_STATE_ERR
 MKL_DSS_INVALID_OPTION
 MKL_DSS_REORDER_ERR
 MKL_DSS_REORDER1_ERR
 MKL_DSS_I32BIT_ERR
 MKL_DSS_FAILURE
 MKL_DSS_OUT_OF_MEMORY
 MKL_DSS_MSG_LVL_ERR
 MKL_DSS_TERM_LVL_ERR

dss_factor_real, dss_factor_complex

Compute factorization of the matrix with previously specified location of non-zero elements.

Syntax

```
MKL_INT dss_factor_real(_MKL_DSS_HANDLE_t *handle, MKL_INT const *opt, void const *rValues)
```

```
MKL_INT dss_factor_complex(_MKL_DSS_HANDLE_t *handle, MKL_INT const *opt, void const *cValues)
```

Include Files

- mkl.h

Description

These routines compute factorization of the matrix whose non-zero locations were previously specified by a call to [dss_define_structure](#) and whose non-zero values are given in the array *rValues*, *cValues* or *Values*. Data type These arrays must be of length *nNonZeros* as defined in a previous call to [dss_define_structure](#).

NOTE

The data type (single or double precision) of *rValues*, *cValues*, *Values* must be in correspondence with precision specified by the parameter *opt* in the routine [dss_create](#).

The *opt* argument can contain one of the following options:

- MKL_DSS_POSITIVE_DEFINITE
- MKL_DSS_INDEFINITE
- MKL_DSS_HERMITIAN_POSITIVE_DEFINITE
- MKL_DSS_HERMITIAN_INDEFINITE

depending on your matrix's type.

NOTE

This routine supports the Progress Routine feature. See [Progress Function](#) section for details.

Input Parameters

<i>handle</i>	Pointer to the data structure storing internal DSS results (MKL_DSS_HANDLE).
<i>opt</i>	Parameter to pass the DSS options. The default value is MKL_DSS_POSITIVE_DEFINITE.
<i>rValues</i>	Array of elements of the matrix <i>A</i> . Real data, single or double precision as it is specified by the parameter <i>opt</i> in the routine <code>dss_create</code> .
<i>cValues</i>	Array of elements of the matrix <i>A</i> . Complex data, single or double precision as it is specified by the parameter <i>opt</i> in the routine <code>dss_create</code> .

Return Values

MKL_DSS_SUCCESS
 MKL_DSS_STATE_ERR
 MKL_DSS_INVALID_OPTION
 MKL_DSS_OPTION_CONFLICT
 MKL_DSS_VALUES_ERR
 MKL_DSS_OUT_OF_MEMORY
 MKL_DSS_ZERO_PIVOT
 MKL_DSS_FAILURE
 MKL_DSS_MSG_LVL_ERR
 MKL_DSS_TERM_LVL_ERR
 MKL_DSS_OOC_MEM_ERR
 MKL_DSS_OOC_OC_ERR
 MKL_DSS_OOC_RW_ERR

dss_solve_real, dss_solve_complex

Compute the corresponding solution vector and place it in the output array.

Syntax

```

MKL_INT dss_solve_real(_MKL_DSS_HANDLE_t *handle, MKL_INT const *opt, void const
*rRhsValues, MKL_INT const *nRhs, void *rSolValues)

MKL_INT dss_solve_complex(_MKL_DSS_HANDLE_t *handle, MKL_INT const *opt, void const
*cRhsValues, MKL_INT const *nRhs, void *cSolValues)

```

Include Files

- `mk1.h`

Description

For each right-hand side column vector defined in the arrays *rRhsValues*, *cRhsValues*, or *RhsValues*, these routines compute the corresponding solution vector and place it in the arrays *rSolValues*, *cSolValues*, or *SolValues* respectively.

NOTE

The data type (single or double precision) of all arrays must be in correspondence with precision specified by the parameter *opt* in the routine `dss_create`.

The lengths of the right-hand side and solution vectors, *nCols* and *nRows* respectively, must be defined in a previous call to `dss_define_structure`.

By default, both routines perform the full solution step (it corresponds to *phase* = 33 in Intel MKL PARDISO). The parameter *opt* enables you to calculate the final solution step-by-step, calling forward and backward substitutions.

If it is set to `MKL_DSS_FORWARD_SOLVE`, the forward substitution (corresponding to *phase* = 331 in Intel MKL PARDISO) is performed;

if it is set to `MKL_DSS_DIAGONAL_SOLVE`, the diagonal substitution (corresponding to *phase* = 332 in Intel MKL PARDISO) is performed, if possible;

if it is set to `MKL_DSS_BACKWARD_SOLVE`, the backward substitution (corresponding to *phase* = 333 in Intel MKL PARDISO) is performed.

For more details about using these substitutions for different types of matrices, see [Separate Forward and Backward Substitution](#) in the Intel MKL PARDISO solver description.

This parameter also can control the number of refinement steps that is used on the solution stage: if it is set to `MKL_DSS_REFINEMENT_OFF`, the maximum number of refinement steps equal to zero, and if it is set to `MKL_DSS_REFINEMENT_ON` (default value), the maximum number of refinement steps is equal to 2.

`MKL_DSS_CONJUGATE_SOLVE` option added to the parameter *opt* enables solving a conjugate transposed system $A^H X = B$ based on the factorization of the matrix *A*. This option is equivalent to the parameter *iparm*[11] = 1 in Intel MKL PARDISO.

`MKL_DSS_TRANSPOSE_SOLVE` option added to the parameter *opt* enables solving a transposed system $A^T X = B$ based on the factorization of the matrix *A*. This option is equivalent to the parameter *iparm*[11] = 2 in Intel MKL PARDISO.

Input Parameters

<i>handle</i>	Pointer to the data structure storing internal DSS results (<code>MKL_DSS_HANDLE</code>).
<i>opt</i>	Parameter to pass the DSS options.
<i>nRhs</i>	Number of the right-hand sides in the system of linear equations.
<i>rRhsValues</i>	Array of size <i>nRows</i> * <i>nRhs</i> . Contains real right-hand side vectors. Real data, single or double precision as it is specified by the parameter <i>opt</i> in the routine <code>dss_create</code> .

<i>cRhsValues</i>	Array of size $nRows * nRhs$. Contains complex right-hand side vectors. Complex data, single or double precision as it is specified by the parameter <i>opt</i> in the routine <code>dss_create</code> .
<i>RhsValues</i>	Array of size $nRows * nRhs$. Contains right-hand side vectors. Real or complex data, single or double precision as it is specified by the parameter <i>opt</i> in the routine <code>dss_create</code> .

Output Parameters

<i>rSolValues</i>	Array of size $nCols * nRhs$. Contains real solution vectors. Real data, single or double precision as it is specified by the parameter <i>opt</i> in the routine <code>dss_create</code> .
<i>cSolValues</i>	Array of size $nCols * nRhs$. Contains complex solution vectors. Complex data, single or double precision as it is specified by the parameter <i>opt</i> in the routine <code>dss_create</code> .

Return Values

MKL_DSS_SUCCESS
 MKL_DSS_STATE_ERR
 MKL_DSS_INVALID_OPTION
 MKL_DSS_OUT_OF_MEMORY
 MKL_DSS_DIAG_ERR
 MKL_DSS_FAILURE
 MKL_DSS_MSG_LVL_ERR
 MKL_DSS_TERM_LVL_ERR
 MKL_DSS_OOC_MEM_ERR
 MKL_DSS_OOC_OC_ERR
 MKL_DSS_OOC_RW_ERR

dss_delete

Deletes all of the data structures created during the solutions process.

Syntax

```
MKL_INT dss_delete(_MKL_DSS_HANDLE_t const *handle, MKL_INT const *opt)
```

Include Files

- `mk1.h`

Description

The routine `dss_delete` deletes all data structures created during the solving process.

Input Parameters

opt

Parameter to pass the DSS options. The default value is
`MKL_DSS_MSG_LVL_WARNING + MKL_DSS_TERM_LVL_ERROR`.

Output Parameters

handle Pointer to the data structure storing internal DSS results
(MKL_DSS_HANDLE).

Return Values

`MKL_DSS_SUCCESS`
`MKL_DSS_STATE_ERR`
`MKL_DSS_INVALID_OPTION`
`MKL_DSS_OUT_OF_MEMORY`
`MKL_DSS_MSG_LVL_ERR`
`MKL_DSS_TERM_LVL_ERR`

dss_statistics

Returns statistics about various phases of the solving process.

Syntax

```
MKL_INT dss_statistics(_MKL_DSS_HANDLE_t *handle, MKL_INT const *opt, _CHARACTER_STR_t
const *statArr, _DOUBLE_PRECISION_t *retValues)
```

Include Files

- `mkl.h`

Description

The `dss_statistics` routine returns statistics about various phases of the solving process. This routine gathers the following statistics:

- time taken to do reordering,
- time taken to do factorization,
- duration of problem solving,
- determinant of the symmetric indefinite input matrix,
- inertia of the symmetric indefinite input matrix,
- number of floating point operations taken during factorization,
- total peak memory needed during the analysis and symbolic factorization,
- permanent memory needed from the analysis and symbolic factorization,
- memory consumption for the factorization and solve phases.

Statistics are returned in accordance with the input string specified by the parameter *statArr*. The value of the statistics is returned in double precision in a return array, which you must allocate beforehand.

For multiple statistics, multiple string constants separated by commas can be used as input. Return values are put into the return array in the same order as specified in the input string.

Statistics can only be requested at the appropriate stages of the solving process. For example, requesting `FactorTime` before a matrix is factored leads to an error.

The following table shows the point at which each individual statistics item can be requested:

Statistics Calling Sequences

Type of Statistics	When to Call
ReorderTime	After <code>dss_reorder</code> is completed successfully.
FactorTime	After <code>dss_factor_real</code> or <code>dss_factor_complex</code> is completed successfully.
SolveTime	After <code>dss_solve_real</code> or <code>dss_solve_complex</code> is completed successfully.
Determinant	After <code>dss_factor_real</code> or <code>dss_factor_complex</code> is completed successfully.
Inertia	After <code>dss_factor_real</code> is completed successfully and the matrix is real, symmetric, and indefinite.
Flops	After <code>dss_factor_real</code> or <code>dss_factor_complex</code> is completed successfully.
Peakmem	After <code>dss_reorder</code> is completed successfully.
Factormem	After <code>dss_reorder</code> is completed successfully.
Solvemem	After <code>dss_factor_real</code> or <code>dss_factor_complex</code> is completed successfully.

Input Parameters

<i>handle</i>	Pointer to the data structure storing internal DSS results (MKL_DSS_HANDLE).										
<i>opt</i>	Parameter to pass the DSS options.										
<i>statArr</i>	Input string that defines the type of the returned statistics. The parameter can include one or more of the following string constants (case of the input string has no effect): <table> <tr> <td>ReorderTime</td><td>Amount of time taken to do the reordering.</td></tr> <tr> <td>FactorTime</td><td>Amount of time taken to do the factorization.</td></tr> <tr> <td>SolveTime</td><td>Amount of time taken to solve the problem after factorization.</td></tr> <tr> <td>Determinant</td><td>Determinant of the matrix A. For real matrices: the determinant is returned as <code>det_pow</code>, <code>det_base</code> in two consecutive return array locations, where $1.0 \leq \text{abs}(\text{det\_base}) < 10.0$ and $\text{determinant} = \text{det\_base} * 10^{(\text{det\_pow})}$. For complex matrices: the determinant is returned as <code>det_pow</code>, <code>det_re</code>, <code>det_im</code> in three consecutive return array locations, where $1.0 \leq \text{abs}(\text{det\_re}) + \text{abs}(\text{det\_im}) < 10.0$ and $\text{determinant} = (\text{det\_re} + j \text{det\_im}) * 10^{(\text{det\_pow})}$.</td></tr> <tr> <td>Inertia</td><td>Inertia of a real symmetric matrix is defined as a triplet of nonnegative integers (p, n, z), where p is the number of positive eigenvalues, n is the number of negative eigenvalues, and z is the number of zero eigenvalues. Inertia is returned as three consecutive return array locations p, n, z.</td></tr> </table>	ReorderTime	Amount of time taken to do the reordering.	FactorTime	Amount of time taken to do the factorization.	SolveTime	Amount of time taken to solve the problem after factorization.	Determinant	Determinant of the matrix A . For real matrices: the determinant is returned as <code>det_pow</code> , <code>det_base</code> in two consecutive return array locations, where $1.0 \leq \text{abs}(\text{det\_base}) < 10.0$ and $\text{determinant} = \text{det\_base} * 10^{(\text{det\_pow})}$. For complex matrices: the determinant is returned as <code>det_pow</code> , <code>det_re</code> , <code>det_im</code> in three consecutive return array locations, where $1.0 \leq \text{abs}(\text{det\_re}) + \text{abs}(\text{det\_im}) < 10.0$ and $\text{determinant} = (\text{det\_re} + j \text{det\_im}) * 10^{(\text{det\_pow})}$.	Inertia	Inertia of a real symmetric matrix is defined as a triplet of nonnegative integers (p, n, z) , where p is the number of positive eigenvalues, n is the number of negative eigenvalues, and z is the number of zero eigenvalues. Inertia is returned as three consecutive return array locations p, n, z .
ReorderTime	Amount of time taken to do the reordering.										
FactorTime	Amount of time taken to do the factorization.										
SolveTime	Amount of time taken to solve the problem after factorization.										
Determinant	Determinant of the matrix A . For real matrices: the determinant is returned as <code>det_pow</code> , <code>det_base</code> in two consecutive return array locations, where $1.0 \leq \text{abs}(\text{det\_base}) < 10.0$ and $\text{determinant} = \text{det\_base} * 10^{(\text{det\_pow})}$. For complex matrices: the determinant is returned as <code>det_pow</code> , <code>det_re</code> , <code>det_im</code> in three consecutive return array locations, where $1.0 \leq \text{abs}(\text{det\_re}) + \text{abs}(\text{det\_im}) < 10.0$ and $\text{determinant} = (\text{det\_re} + j \text{det\_im}) * 10^{(\text{det\_pow})}$.										
Inertia	Inertia of a real symmetric matrix is defined as a triplet of nonnegative integers (p, n, z) , where p is the number of positive eigenvalues, n is the number of negative eigenvalues, and z is the number of zero eigenvalues. Inertia is returned as three consecutive return array locations p, n, z .										

Computing inertia can lead to incorrect results for matrixes with a cluster of eigenvalues which are near 0.

Inertia of a k -by- k real symmetric positive definite matrix is always $(k, 0, 0)$. Therefore *Inertia* is returned only in cases of real symmetric indefinite matrices. For all other matrix types, an error message is returned.

Flops	Number of floating point operations performed during the factorization.
Peakmem	Total peak memory in kilobytes that the solver needs during the analysis and symbolic factorization phase.
Factormem	Permanent memory in kilobytes that the solver needs from the analysis and symbolic factorization phase in the factorization and solve phases.
Solvemem	Total double precision memory consumption (kilobytes) of the solver for the factorization and solve phases.

Output Parameters

retValues Value of the statistics returned.

Finding 'time used to reorder' and 'inertia' of a matrix

The example below illustrates the use of the `dss_statistics` routine.

To find the above values, call `dss_statistics(handle, opt, statArr, retValue)`, where *statArr* is "ReorderTime,Inertia"

In this example, *retValue* has the following values:

<i>retValue</i> [0]	Time to reorder.
<i>retValue</i> [1]	Positive Eigenvalues.
<i>retValue</i> [2]	Negative Eigenvalues.
<i>retValue</i> [3]	Zero Eigenvalues.

Return Values

MKL_DSS_SUCCESS
 MKL_DSS_INVALID_OPTION
 MKL_DSS_STATISTICS_INVALID_MATRIX
 MKL_DSS_STATISTICS_INVALID_STATE
 MKL_DSS_STATISTICS_INVALID_STRING
 MKL_DSS_MSG_LVL_ERR
 MKL_DSS_TERM_LVL_ERR

Iterative Sparse Solvers based on Reverse Communication Interface (RCI ISS)

Intel MKL supports iterative sparse solvers (ISS) based on the reverse communication interface (RCI), referred to here as the RCI ISS interface. The RCI ISS interface implements a group of user-callable routines that are used in the step-by-step solving process of a symmetric positive definite system (RCI conjugate gradient solver, or RCI CG), and of a non-symmetric indefinite (non-degenerate) system (RCI flexible generalized minimal residual solver, or RCI FGMRES) of linear algebraic equations. This interface uses the general RCI scheme described in [Dong95].

See the [Appendix A Linear Solvers Basics](#) for discussion of terms and concepts related to the ISS routines.

The term *RCI* indicates that when the solver needs the results of certain operations (for example, matrix-vector multiplications), the user performs them and passes the result to the solver. This makes the solver more universal as it is independent of the specific implementation of the operations like the matrix-vector multiplication. To perform such operations, the user can use the built-in sparse matrix-vector multiplications and triangular solvers routines described in [Sparse BLAS Level 2 and Level 3 Routines](#).

NOTE

The RCI CG solver is implemented in two versions: for system of equations with a single right-hand side, and for systems of equations with multiple right-hand sides.

The CG method may fail to compute the solution or compute the wrong solution if the matrix of the system is not symmetric and not positive definite.

The FGMRES method may fail if the matrix is degenerate.

Table "RCI CG Interface Routines" lists the names of the routines, and describes their general use.

RCI ISS Interface Routines

Routine	Description
dcg_init , dcgmrhs_init , dfgmres_init	Initializes the solver.
dcg_check , dcgmrhs_check , dfgmres_check	Checks the consistency and correctness of the user defined data.
dcg , dcgmrhs , dfgmres	Computes the approximate solution vector.
dcg_get , dcgmrhs_get , dfgmres_get	Retrieves the number of the current iteration.

The Intel MKL RCI ISS interface routines are normally invoked in this order:

1. `<system_type>_init`
2. `<system_type>_check`
3. `<system_type>`
4. `<system_type>_get`

Advanced users can change that order if they need it. Others should follow the above order of calls.

The following diagram indicates the typical order in which the RCI ISS interface routines are invoked.

Typical Order for Invoking RCI ISS interface Routines

See the code examples that use the RCI ISS interface routines to solve systems of linear equations in the Intel MKL installation directory.

- `examples/solverc/source`

CG Interface Description

Each routine for the RCI CG solver is implemented in two versions: for a system of equations with a single right-hand side (SRHS), and for a system of equations with multiple right-hand sides (MRHS). The names of routines for a system with MRHS contain the suffix `mrhs`.

Routine Options

All of the RCI CG routines have common parameters for passing various options to the routines (see [CG Common Parameters](#)). The values for these parameters can be changed during computations.

User Data Arrays

Many of the RCI CG routines take arrays of user data as input. For example, user arrays are passed to the routine `dcg` to compute the solution of a system of linear algebraic equations. The Intel MKL RCI CG routines do not make copies of the user input arrays to minimize storage requirements and improve overall run-time efficiency.

CG Common Parameters

NOTE

The default and initial values listed below are assigned to the parameters by calling the `dcg_init/dcgmrhs_init` routine.

n

MKL_INT, this parameter sets the size of the problem in the `dcg_init/dcgmrhs_init` routine. All the other routines use the `ipar[0]` parameter instead. Note that the coefficient matrix A is a square matrix of size $n \times n$.

<code>x</code>	double array of size n for SRHS, or matrix of size $(n \times nrhs)$ for MRHS. This parameter contains the current approximation to the solution. Before the first call to the <code>dcg/dcgmrhs</code> routine, it contains the initial approximation to the solution.
<code>nrhs</code>	MKL_INT, this parameter sets the number of right-hand sides for MRHS routines.
<code>b</code>	double array containing a single right-hand side vector, or matrix of size $n \times nrhs$ containing right-hand side vectors.
<code>RCI_request</code>	MKL_INT, this parameter gives information about the result of work of the RCI CG routines. Negative values of the parameter indicate that the routine completed with errors or warnings. The 0 value indicates successful completion of the task. Positive values mean that you must perform specific actions: <code>RCI_request= 1</code> multiply the matrix by <code>tmp [0:n - 1]</code>, put the result in <code>tmp[n:2*n - 1]</code>, and return the control to the <code>dcg/dcgmrhs</code> routine; <code>RCI_request= 2</code> to perform the stopping tests. If they fail, return the control to the <code>dcg/dcgmrhs</code> routine. If the stopping tests succeed, it indicates that the solution is found and stored in the <code>x</code> array; <code>RCI_request= 3</code> for SRHS: apply the preconditioner to <code>tmp[2*n:3*n - 1]</code>, put the result in <code>tmp[3*n:4*n - 1]</code>, and return the control to the <code>dcg</code> routine; for MRHS: apply the preconditioner to <code>tmp[2+ipar[2]*n:(3 + ipar[2])*n - 1]</code>, put the result in <code>tmp[3*n:4*n - 1]</code>, and return the control to the <code>dcgmrhs</code> routine. Note that the <code>dcg_get/dcgmrhs_get</code> routine does not change the parameter <code>RCI_request</code>. This enables use of this routine inside the <i>reverse communication</i> computations.
<code>ipar</code>	MKL_INT array, of size 128 for SRHS, and of size $(128+2 \times nrhs)$ for MRHS. This parameter specifies the integer set of data for the RCI CG computations: <code>ipar[0]</code> specifies the size of the problem. The <code>dcg_init/dcgmrhs_init</code> routine assigns <code>ipar[0]=n</code>. All the other routines use this parameter instead of n. There is no default value for this parameter. <code>ipar[1]</code> specifies the type of output for error and warning messages generated by the RCI CG routines. The default value 6 means that all messages are displayed on the screen. Otherwise, the error and warning messages are written to the newly created files <code>dcg_errors.txt</code> and <code>dcg_check_warnings.txt</code>, respectively. Note that

	if <i>ipar</i> [5] and <i>ipar</i> [6] parameters are set to 0, error and warning messages are not generated at all.
<i>ipar</i> [2]	for SRHS: contains the current stage of the RCI CG computations. The initial value is 1; for MRHS: contains the number of the right-hand side for which the calculations are currently performed.
WARNING Avoid altering this variable during computations.	
<i>ipar</i> [3]	contains the current iteration number. The initial value is 0.
<i>ipar</i> [4]	specifies the maximum number of iterations. The default value is <code>min(150, n)</code> .
<i>ipar</i> [5]	if the value is not equal to 0, the routines output error messages in accordance with the parameter <i>ipar</i> [1]. Otherwise, the routines do not output error messages at all, but return a negative value of the parameter <i>RCI_request</i> . The default value is 1.
<i>ipar</i> [6]	if the value is not equal to 0, the routines output warning messages in accordance with the parameter <i>ipar</i> [1]. Otherwise, the routines do not output warning messages at all, but they return a negative value of the parameter <i>RCI_request</i> . The default value is 1.
<i>ipar</i> [7]	if the value is not equal to 0, the <i>dcg/dcgmrhs</i> routine performs the stopping test for the maximum number of iterations: <i>ipar</i> [3] ≤ <i>ipar</i> [4]. Otherwise, the method is stopped and the corresponding value is assigned to the <i>RCI_request</i> . If the value is 0, the routine does not perform this stopping test. The default value is 1.
<i>ipar</i> [8]	if the value is not equal to 0, the <i>dcg/dcgmrhs</i> routine performs the residual stopping test: <i>dpar</i> (5) ≤ <i>dpar</i> (4) = <i>dpar</i> (1) * <i>dpar</i> (3) + <i>dpar</i> (2). Otherwise, the method is stopped and corresponding value is assigned to the <i>RCI_request</i> . If the value is 0, the routine does not perform this stopping test. The default value is 0.
<i>ipar</i> [9]	if the value is not equal to 0, the <i>dcg/dcgmrhs</i> routine requests a user-defined stopping test by setting the output parameter <i>RCI_request</i> =2. If the value is 0, the routine does not perform the user defined stopping test. The default value is 1.

NOTE

At least one of the parameters *ipar*[7]-*ipar*[9] must be set to 1.

ipar[10]

if the value is equal to 0, the *dcg/dcgmrhs* routine runs the non-preconditioned version of the corresponding CG method. Otherwise, the routine runs the preconditioned version of the CG method, and by setting the output parameter *RCI_request*=3, indicates that you must perform the preconditioning step. The default value is 0.

ipar[11:127]

are reserved and not used in the current RCI CG SRHS and MRHS routines.

NOTE

For future compatibility, you must declare the array *ipar* with length 128 for a single right-hand side.

ipar[11:127 +
2**nrhs*]

are reserved for internal use in the current RCI CG SRHS and MRHS routines.

NOTE

For future compatibility, you must declare the array *ipar* with length 128+2**nrhs* for multiple right-hand sides.

dpar

double array, for SRHS of size 128, for MRHS of size (128+2**nrhs*); this parameter is used to specify the double precision set of data for the RCI CG computations, specifically:

dpar[0]

specifies the relative tolerance. The default value is 1.0×10^{-6} .

dpar[1]

specifies the absolute tolerance. The default value is 0.0.

dpar[2]

specifies the square norm of the initial residual (if it is computed in the *dcg/dcgmrhs* routine). The initial value is 0.0.

dpar[3]

service variable equal to $dpar[0] * dpar[2] + dpar[1]$ (if it is computed in the *dcg/dcgmrhs* routine). The initial value is 0.0.

dpar[4]

specifies the square norm of the current residual. The initial value is 0.0.

<code>dpar[5]</code>	specifies the square norm of residual from the previous iteration step (if available). The initial value is 0.0.
<code>dpar[6]</code>	contains the <i>alpha</i> parameter of the CG method. The initial value is 0.0.
<code>dpar[7]</code>	contains the <i>beta</i> parameter of the CG method, it is equal to <code>dpar[4]/dpar[5]</code> The initial value is 0.0.
<code>dpar[8:127]</code>	are reserved and not used in the current RCI CG SRHS and MRHS routines.

NOTE

For future compatibility, you must declare the array `dpar` with length 128 for a single right-hand side.

<code>dpar(9:128+2*nrhs)</code> <code>[8:127 + 2*nrhs]</code>	are reserved for internal use in the current RCI CG SRHS and MRHS routines.

NOTE

For future compatibility, you must declare the array `dpar` with length `128+2*nrhs` for multiple right-hand sides.

`tmp`

double array of size $(n*4)$ for SRHS, and $(n*(3+nrhs))$ for MRHS. This parameter is used to supply the double precision temporary space for the RCI CG computations, specifically:

<code>tmp[0:n - 1]</code>	specifies the current search direction. The initial value is 0.0.
<code>tmp[n:2*n - 1]</code>	contains the matrix multiplied by the current search direction. The initial value is 0.0.
<code>tmp[2*n:3*n - 1]</code>	contains the current residual. The initial value is 0.0.
<code>tmp[3*n:4*n - 1]</code>	contains the inverse of the preconditioner applied to the current residual for the SRHS version of CG. There is no initial value for this parameter.
<code>tmp[4*n: (4 + nrhs)*n - 1]</code>	contains the inverse of the preconditioner applied to the current residual for the MRHS version of CG. There is no initial value for this parameter.

NOTE

You can define this array in the code using RCI CG SRHS as `double tmp[3*n]` if you run only non-preconditioned CG iterations.

FGMRES Interface Description

Routine Options

All of the RCI FGMRES routines have common parameters for passing various options to the routines (see [FGMRES Common Parameters](#)). The values for these parameters can be changed during computations.

User Data Arrays

Many of the RCI FGMRES routines take arrays of user data as input. For example, user arrays are passed to the routine `dfgmres` to compute the solution of a system of linear algebraic equations. To minimize storage requirements and improve overall run-time efficiency, the Intel MKL RCI FGMRES routines do not make copies of the user input arrays.

FGMRES Common Parameters

NOTE

The default and initial values listed below are assigned to the parameters by calling the `dfgmres_init` routine.

n	MKL_INT, this parameter sets the size of the problem in the <code>dfgmres_init</code> routine. All the other routines use the <code>ipar[0]</code> parameter instead. Note that the coefficient matrix A is a square matrix of size $n \times n$.
x	double array, this parameter contains the current approximation to the solution vector. Before the first call to the <code>dfgmres</code> routine, it contains the initial approximation to the solution vector.
b	double array, this parameter contains the right-hand side vector. Depending on user requests (see the parameter <code>ipar[12]</code>), it might contain the approximate solution after execution.
$RCI\_request$	MKL_INT, this parameter gives information about the result of work of the RCI FGMRES routines. Negative values of the parameter indicate that the routine completed with errors or warnings. The 0 value indicates successful completion of the task. Positive values mean that you must perform specific actions: <code>RCI_request= 1</code> multiply the matrix by <code>tmp[ipar[21] - 1:ipar[21] + n - 2]</code>, put the result in <code>tmp[ipar[22] - 1:ipar[22] + n - 2]</code>, and return the control to the <code>dfgmres</code> routine; <code>RCI_request= 2</code> perform the stopping tests. If they fail, return the control to the <code>dfgmres</code> routine. Otherwise, the solution can be updated by a subsequent call to <code>dfgmres_get</code> routine; <code>RCI_request= 3</code> apply the preconditioner to <code>tmp[ipar[21] - 1:ipar[21] + n - 2]</code>, put the result in <code>tmp[ipar[22] - 1:ipar[22] + n - 2]</code>, and return the control to the <code>dfgmres</code> routine.

`RCI_request= 4` check if the norm of the current orthogonal vector is zero, within the rounding or computational errors. Return the control to the `dfgmres` routine if it is not zero, otherwise complete the solution process by calling `dfgmres_get` routine.

`ipar[128]`

MKL_INT array, this parameter specifies the integer set of data for the RCI FGMRES computations:

`ipar[0]` specifies the size of the problem. The `dfgmres_init` routine assigns `ipar[0]=n`. All the other routines uses this parameter instead of `n`. There is no default value for this parameter.

`ipar[1]` specifies the type of output for error and warning messages that are generated by the RCI FGMRES routines. The default value 6 means that all messages are displayed on the screen. Otherwise the error and warning messages are written to the newly created file `MKL_RCI_FGMRES_Log.txt`. Note that if `ipar[5]` and `ipar[6]` parameters are set to 0, error and warning messages are not generated at all.

`ipar[2]` contains the current stage of the RCI FGMRES computations. The initial value is 1.

WARNING

Avoid altering this variable during computations.

`ipar[3]` contains the current iteration number. The initial value is 0.

`ipar[4]` specifies the maximum number of iterations. The default value is `min (150,n)`.

`ipar[5]` if the value is not 0, the routines output error messages in accordance with the parameter `ipar[1]`. If it is 0, the routines do not output error messages at all, but return a negative value of the parameter `RCI_request`. The default value is 1.

`ipar[6]` if the value is not 0, the routines output warning messages in accordance with the parameter `ipar[1]`. Otherwise, the routines do not output warning messages at all, but they return a negative value of the parameter `RCI_request`. The default value is 1.

<i>ipar</i> [7]	if the value is not equal to 0, the <i>dfgmres</i> routine performs the stopping test for the maximum number of iterations: <i>ipar</i> [3] ≤ <i>ipar</i> [4]. If the value is 0, the <i>dfgmres</i> routine does not perform this stopping test. The default value is 1.
<i>ipar</i> [8]	if the value is not 0, the <i>dfgmres</i> routine performs the residual stopping test: <i>dpar</i> [4] ≤ <i>dpar</i> [3]. If the value is 0, the <i>dfgmres</i> routine does not perform this stopping test. The default value is 0.
<i>ipar</i> [9]	if the value is not 0, the <i>dfgmres</i> routine indicates that the user-defined stopping test should be performed by setting <i>RCI_request</i> =2. If the value is 0, the <i>dfgmres</i> routine does not perform the user-defined stopping test. The default value is 1.
NOTE At least one of the parameters <i>ipar</i> [7]- <i>ipar</i> [9] must be set to 1.	
<i>ipar</i> [10]	if the value is 0, the <i>dfgmres</i> routine runs the non-preconditioned version of the FGMRES method. Otherwise, the routine runs the preconditioned version of the FGMRES method, and requests that you perform the preconditioning step by setting the output parameter <i>RCI_request</i> =3. The default value is 0.
<i>ipar</i> [11]	if the value is not equal to 0, the <i>dfgmres</i> routine performs the automatic test for zero norm of the currently generated vector: <i>dpar</i> [6] ≤ <i>dpar</i> [7], where <i>dpar</i> [7] contains the tolerance value. Otherwise, the routine indicates that you must perform this check by setting the output parameter <i>RCI_request</i> =4. The default value is 0.
<i>ipar</i> [12]	if the value is equal to 0, the <i>dfgmres_get</i> routine updates the solution to the vector <i>x</i> according to the computations done by the <i>dfgmres</i> routine. If the value is positive, the routine writes the solution to the right-hand side vector <i>b</i> . If the value is negative, the routine returns only the number of the current iteration, and does not update the solution. The default value is 0.

NOTE

It is possible to call the `dfgmres_get` routine at any place in the code, but you must pay special attention to the parameter `ipar[12]`. The RCI FGMRES iterations can be continued after the call to `dfgmres_get` routine only if the parameter `ipar[12]` is not equal to zero. If `ipar[12]` is positive, then the updated solution overwrites the right-hand side in the vector `b`. If you want to run the restarted version of FGMRES with the same right-hand side, then it must be saved in a different memory location before the first call to the `dfgmres_get` routine with positive `ipar[12]`.

`ipar[13]`

contains the internal iteration counter that counts the number of iterations before the restart takes place. The initial value is 0.

WARNING

Do not alter this variable during computations.

`ipar[14]`

specifies the number of the non-restarted FGMRES iterations. To run the restarted version of the FGMRES method, assign the number of iterations to `ipar[14]` before the restart. The default value is $\min(150, n)$, which means that by default the non-restarted version of FGMRES method is used.

`ipar[15]`

service variable specifying the location of the rotated Hessenberg matrix from which the matrix stored in the packed format (see [Matrix Arguments](#) in the Appendix B for details) is started in the `tmp` array.

`ipar[16]`

service variable specifying the location of the rotation cosines from which the vector of cosines is started in the `tmp` array.

`ipar[17]`

service variable specifying the location of the rotation sines from which the vector of sines is started in the `tmp` array.

`ipar[18]`

service variable specifying the location of the rotated residual vector from which the vector is started in the `tmp` array.

`ipar[19]`

service variable, specifies the location of the least squares solution vector from which the vector is started in the `tmp` array.

<i>ipar</i> [20]	service variable specifying the location of the set of preconditioned vectors from which the set is started in the <i>tmp</i> array. The memory locations in the <i>tmp</i> array starting from <i>ipar</i> [20] are used only for the preconditioned FGMRES method.
<i>ipar</i> [21]	specifies the memory location from which the first vector (source) used in operations requested via <i>RCI_request</i> is started in the <i>tmp</i> array.
<i>ipar</i> [22]	specifies the memory location from which the second vector (output) used in operations requested via <i>RCI_request</i> is started in the <i>tmp</i> array.
<i>ipar</i> [23:127]	are reserved and not used in the current RCI FGMRES routines.

NOTE

You must declare the array *ipar* with length 128. While defining the array in the code as *ipar*[23] works, there is no guarantee of future compatibility with Intel MKL.

dpar(128)

double array, this parameter specifies the double precision set of data for the RCI CG computations, specifically:

<i>dpar</i> [0]	specifies the relative tolerance. The default value is 1.0e-6.
<i>dpar</i> [1]	specifies the absolute tolerance. The default value is 0.0e-0.
<i>dpar</i> [2]	specifies the Euclidean norm of the initial residual (if it is computed in the <i>dfgmres</i> routine). The initial value is 0.0.
<i>dpar</i> [3]	service variable equal to $dpar[0] * dpar[2] + dpar[1]$ (if it is computed in the <i>dfgmres</i> routine). The initial value is 0.0.
<i>dpar</i> [4]	specifies the Euclidean norm of the current residual. The initial value is 0.0.
<i>dpar</i> [5]	specifies the Euclidean norm of residual from the previous iteration step (if available). The initial value is 0.0.
<i>dpar</i> [6]	contains the norm of the generated vector. The initial value is 0.0.

NOTE

In terms of [Saad03] this parameter is the coefficient $h_{k+1,k}$ of the Hessenberg matrix.

`dpar[7]` contains the tolerance for the zero norm of the currently generated vector. The default value is 1.0e-12.

`dpar[8:127]` are reserved and not used in the current RCI FGMRES routines.

NOTE

You must declare the array `dpar` with length 128. While defining the array in the code as `double dpar[8]` works, there is no guarantee of future compatibility with Intel MKL.

`tmp`

double array of size $((2*ipar[14] + 1)*n + ipar[14]*(ipar[14] + 9)/2 + 1)$ used to supply the double precision temporary space for the RCI FGMRES computations, specifically:

`tmp[0:ipar[15] - 2]` contains the sequence of vectors generated by the FGMRES method. The initial value is 0.0.

`tmp[ipar[15] - 1:ipar[16] - 2]` contains the rotated Hessenberg matrix generated by the FGMRES method; the matrix is stored in the packed format. There is no initial value for this part of `tmp` array.

`tmp[ipar[16] - 1:ipar[17] - 2]` contains the rotation cosines vector generated by the FGMRES method. There is no initial value for this part of `tmp` array.

`tmp[ipar[17] - 1:ipar[18] - 2]` contains the rotation sines vector generated by the FGMRES method. There is no initial value for this part of `tmp` array.

`tmp[ipar[18] - 1:ipar[19] - 2]` contains the rotated residual vector generated by the FGMRES method. There is no initial value for this part of `tmp` array.

`tmp[ipar[19] - 1:ipar[20] - 2]` contains the solution vector to the least squares problem generated by the FGMRES method. There is no initial value for this part of `tmp` array.

`tmp[ipar[20] - 1:*)` contains the set of preconditioned vectors generated for the FGMRES method by the user. This part of `tmp` array is not used if the non-preconditioned version of FGMRES method is called. There is no initial value for this part of `tmp` array.

NOTE

You can define this array in the code as `double tmp[ (2*ipar[14] + 1)*n + ipar[14]*(ipar[14] + 9)/2 + 1 ]` if you run only non-preconditioned FGMRES iterations.

RCI ISS Routines

dcg_init

Initializes the solver.

Syntax

```
void dcg_init (const MKL_INT *n , const double *x , const double *b , MKL_INT
*RCI_request , MKL_INT *ipar , double *dpar , double *tmp );
```

Include Files

- mkl.h

Description

The routine `dcg_init` initializes the solver. After initialization, all subsequent invocations of the Intel MKL RCI CG routines use the values of all parameters returned by the routine `dcg_init`. Advanced users can skip this step and set the values in the `ipar` and `dpar` arrays directly.

CAUTION

You can modify the contents of these arrays after they are passed to the solver routine only if you are sure that the values are correct and consistent. You can perform a basic check for correctness and consistency by calling the `dcg_check` routine, but it does not guarantee that the method will work correctly.

Input Parameters

<i>n</i>	Sets the size of the problem.
<i>x</i>	Array of size <i>n</i> . Contains the initial approximation to the solution vector. Normally it is equal to 0 or to <i>b</i> .
<i>b</i>	Array of size <i>n</i> . Contains the right-hand side vector.

Output Parameters

<i>RCI_request</i>	Gives information about the result of the routine.
<i>ipar</i>	Array of size 128. Refer to the CG Common Parameters .
<i>dpar</i>	Array of size 128. Refer to the CG Common Parameters .

tmp Array of size $(n*4)$. Refer to the [CG Common Parameters](#).

Return Values

RCI_request = 0 Indicates that the task completed normally.

RCI_request = -10000 Indicates failure to complete the task.

dcg_check

Checks consistency and correctness of the user defined data.

Syntax

```
void dcg_check (const MKL_INT *n , const double *x , const double *b , MKL_INT
*RCI_request , MKL_INT *ipar , double *dpar , double *tmp );
```

Include Files

- mkl.h

Description

The routine `dcg_check` checks consistency and correctness of the parameters to be passed to the solver routine `dcg`. However this operation does not guarantee that the solver returns the correct result. It only reduces the chance of making a mistake in the parameters of the method. Skip this operation only if you are sure that the correct data is specified in the solver parameters.

The lengths of all vectors must be defined in a previous call to the `dcg_init` routine.

Input Parameters

n Sets the size of the problem.

x Array of size *n*. Contains the initial approximation to the solution vector. Normally it is equal to 0 or to *b*.

b Array of size *n*. Contains the right-hand side vector.

Output Parameters

RCI_request Gives information about result of the routine.

ipar Array of size 128. Refer to the [CG Common Parameters](#).

dpar Array of size 128. Refer to the [CG Common Parameters](#).

tmp Array of size $(n*4)$. Refer to the [CG Common Parameters](#).

Return Values

RCI_request = 0 Indicates that the task completed normally.

RCI_request = -1100 Indicates that the task is interrupted and the errors occur.

RCI_request = -1001 Indicates that there are some warning messages.

`RCI_request = -1010`

Indicates that the routine changed some parameters to make them consistent or correct.

`RCI_request = -1011`

Indicates that there are some warning messages and that the routine changed some parameters.

dcg

Computes the approximate solution vector.

Syntax

```
void dcg (const MKL_INT *n , double *x , const double *b , MKL_INT *RCI_request ,
MKL_INT *ipar , double *dpar , double *tmp );
```

Include Files

- `mk1.h`

Description

The `dcg` routine computes the approximate solution vector using the CG method [Young71]. The routine `dcg` uses the vector in the array `x` before the first call as an initial approximation to the solution. The parameter `RCI_request` gives you information about the task completion and requests results of certain operations that are required by the solver.

Note that lengths of all vectors must be defined in a previous call to the `dcg_init` routine.

Input Parameters

<code>n</code>	Sets the size of the problem.
<code>x</code>	Array of size <code>n</code> . Contains the initial approximation to the solution vector.
<code>b</code>	Array of size <code>n</code> . Contains the right-hand side vector.
<code>tmp</code>	Array of size <code>(n*4)</code> . Refer to the CG Common Parameters .

Output Parameters

<code>RCI_request</code>	Gives information about result of work of the routine.
<code>x</code>	Array of size <code>n</code> . Contains the updated approximation to the solution vector.
<code>ipar</code>	Array of size <code>128</code> . Refer to the CG Common Parameters .
<code>dpar</code>	Array of size <code>128</code> . Refer to the CG Common Parameters .
<code>tmp</code>	Array of size <code>(n*4)</code> . Refer to the CG Common Parameters .

Return Values

`RCI_request = 0`

Indicates that the task completed normally and the solution is found and stored in the vector `x`. This occurs only if the stopping tests are fully automatic. For the user defined stopping tests, see the description of the `RCI_request = 2`.

<code>RCI_request=-1</code>	Indicates that the routine was interrupted because the maximum number of iterations was reached, but the relative stopping criterion was not met. This situation occurs only if you request both tests.
<code>RCI_request=-2</code>	Indicates that the routine was interrupted because of an attempt to divide by zero. This situation happens if the matrix is non-positive definite or almost non-positive definite.
<code>RCI_request=- 10</code>	Indicates that the routine was interrupted because the residual norm is invalid. This usually happens because the value <code>dpar[5]</code> was altered outside of the routine, or the <code>dcg_check</code> routine was not called.
<code>RCI_request=-11</code>	Indicates that the routine was interrupted because it enters the infinite cycle. This usually happens because the values <code>ipar[7]</code> , <code>ipar[8]</code> , <code>ipar[9]</code> were altered outside of the routine, or the <code>dcg_check</code> routine was not called.
<code>RCI_request= 1</code>	Indicates that you must multiply the matrix by <code>tmp[0:n - 1]</code> , put the result in the <code>tmp[n:2*n - 1]</code> , and return control back to the routine <code>dcg</code> .
<code>RCI_request= 2</code>	Indicates that you must perform the stopping tests. If they fail, return control back to the <code>dcg</code> routine. Otherwise, the solution is found and stored in the vector <code>x</code> .
<code>RCI_request= 3</code>	Indicates that you must apply the preconditioner to <code>[2*n: 3*n - 1]</code> , put the result in the <code>[3*n:4*n - 1]</code> , and return control back to the routine <code>dcg</code> .

dcg_get

Retrieves the number of the current iteration.

Syntax

```
void dcg_get (const MKL_INT *n , const double *x , const double *b , const MKL_INT
*RCI_request , const MKL_INT *ipar , const double *dpar , const double *tmp , MKL_INT
*itercount );
```

Include Files

- `mkh.h`

Description

The routine `dcg_get` retrieves the current iteration number of the solutions process.

Input Parameters

<code>n</code>	Sets the size of the problem.
<code>x</code>	Array of size <code>n</code> . Contains the approximation vector to the solution.
<code>b</code>	Array of size <code>n</code> . Contains the right-hand side vector.

<code>RCI_request</code>	This parameter is not used.
<code>ipar</code>	Array of size 128. Refer to the CG Common Parameters .
<code>dpar</code>	Array of size 128. Refer to the CG Common Parameters .
<code>tmp</code>	Array of size $(n*4)$. Refer to the CG Common Parameters .

Output Parameters

<code>itercount</code>	Returns the current iteration number.

Return Values

The routine `dcg_get` has no return values.

dcgmrhs_init

Initializes the RCI CG solver with MHRS.

Syntax

```
void dcgmrhs_init (const MKL_INT *n , const double *x , const MKL_INT *nrhs , const
double *b , const MKL_INT *method , MKL_INT *RCI_request , MKL_INT *ipar , double
*dpar , double *tmp );
```

Include Files

- `mkl.h`

Description

The routine `dcgmrhs_init` initializes the solver. After initialization all subsequent invocations of the Intel MKL RCI CG with multiple right-hand sides (MRHS) routines use the values of all parameters that are returned by `dcgmrhs_init`. Advanced users may skip this step and set the values to these parameters directly in the appropriate routines.

WARNING

You can modify the contents of these arrays after they are passed to the solver routine only if you are sure that the values are correct and consistent. You can perform a basic check for correctness and consistency by calling the `dcgmrhs_check` routine, but it does not guarantee that the method will work correctly.

Input Parameters

<code>n</code>	Sets the size of the problem.
<code>x</code>	Array of size $n*nrhs$. Contains the initial approximation to the solution vectors. Normally it is equal to 0 or to <code>b</code> .
<code>nrhs</code>	Sets the number of right-hand sides.
<code>b</code>	Array of size $n*nrhs$. Contains the right-hand side vectors.
<code>method</code>	Specifies the method of solution:

A value of 1 indicates CG with multiple right-hand sides (default value)

Output Parameters

<code>RCI_request</code>	Gives information about the result of the routine.
<code>ipar</code>	Array of size $(128+2*nrhs)$. Refer to the CG Common Parameters .
<code>dpar</code>	Array of size $(128+2*nrhs)$. Refer to the CG Common Parameters .
<code>tmp</code>	Array of size $(n*(3+nrhs))$. Refer to the CG Common Parameters .

Return Values

<code>RCI_request= 0</code>	Indicates that the task completed normally.
<code>RCI_request= -10000</code>	Indicates failure to complete the task.

dcgmrhs_check

Checks consistency and correctness of the user defined data.

Syntax

```
void dcgmrhs_check (const MKL_INT *n , const double *x , const MKL_INT *nrhs , const
double *b , MKL_INT *RCI_request , MKL_INT *ipar , double *dpar , double *tmp );
```

Include Files

- `mk1.h`

Description

The routine `dcgmrhs_check` checks the consistency and correctness of the parameters to be passed to the solver routine `dcgmrhs`. While this operation reduces the chance of making a mistake in the parameters, it does not guarantee that the solver returns the correct result.

If you are sure that the correct data is *specified* in the solver parameters, you can skip this operation.

The lengths of all vectors must be defined in a previous call to the `dcgmrhs_init` routine.

Input Parameters

<code>n</code>	Sets the size of the problem.
<code>x</code>	Array of size $n*nrhs$. Contains the initial approximation to the solution vectors. Normally it is equal to 0 or to <code>b</code> .
<code>nrhs</code>	This parameter sets the number of right-hand sides.
<code>b</code>	Array of size $n*nrhs$. Contains the right-hand side vectors.

Output Parameters

<code>RCI_request</code>	Returns information about the results of the routine.

<i>ipar</i>	Array of size $(128+2*nrhs)$. Refer to the CG Common Parameters .
<i>dpar</i>	Array of size $(128+2*nrhs)$. Refer to the CG Common Parameters .
<i>tmp</i>	Array of size $(n*(3+nrhs))$. Refer to the CG Common Parameters .

Return Values

<i>RCI_request</i> = 0	Indicates that the task completed normally.
<i>RCI_request</i> = -1100	Indicates that the task is interrupted and the errors occur.
<i>RCI_request</i> = -1001	Indicates that there are some warning messages.
<i>RCI_request</i> = -1010	Indicates that the routine changed some parameters to make them consistent or correct.
<i>RCI_request</i> = -1011	Indicates that there are some warning messages and that the routine changed some parameters.

dcgmrhs

Computes the approximate solution vectors.

Syntax

```
void dcgmrhs (const MKL_INT *n , double *x , const MKL_INT *nrhs , const double *b ,
MKL_INT *RCI_request , MKL_INT *ipar , double *dpar , double *tmp );
```

Include Files

- `mk1.h`

Description

The routine `dcgmrhs` computes approximate solution vectors using the CG with multiple right-hand sides (MRHS) method [Young71]. The routine `dcgmrhs` uses the value that was in the *x* before the first call as an initial approximation to the solution. The parameter *RCI_request* gives information about task completion status and requests results of certain operations that are required by the solver.

Note that lengths of all vectors are assumed to have been defined in a previous call to the `dcgmrhs_init` routine.

Input Parameters

<i>n</i>	Sets the size of the problem, and the sizes of arrays <i>x</i> and <i>b</i> .
<i>x</i>	Array of size $n*nrhs$. Contains the initial approximation to the solution vectors.
<i>nrhs</i>	Sets the number of right-hand sides.
<i>b</i>	Array of size $n*nrhs$. Contains the right-hand side vectors.
<i>tmp</i>	Array of size $(n, 3+nrhs)$. Refer to the CG Common Parameters .

Output Parameters

<i>RCI_request</i>	Gives information about result of work of the routine.
<i>x</i>	Array of size $(n*nrhs)$. Contains the updated approximation to the solution vectors.
<i>ipar</i>	Array of size $(128+2*nrhs)$. Refer to the CG Common Parameters .
<i>dpar</i>	Array of size $(128+2*nrhs)$. Refer to the CG Common Parameters .
<i>tmp</i>	Array of size $(n*(3+nrhs))$. Refer to the CG Common Parameters .

Return Values

<i>RCI_request</i> =0	Indicates that the task completed normally and the solution is found and stored in the vector <i>x</i> . This occurs only if the stopping tests are fully automatic. For the user defined stopping tests, see the description of the <i>RCI_request</i> = 2.
<i>RCI_request</i> =-1	Indicates that the routine was interrupted because the maximum number of iterations was reached, but the relative stopping criterion was not met. This situation occurs only if both tests are requested by the user.
<i>RCI_request</i> =-2	The routine was interrupted because of an attempt to divide by zero. This situation happens if the matrix is non-positive definite or almost non-positive definite.
<i>RCI_request</i> =- 10	Indicates that the routine was interrupted because the residual norm is invalid. This usually happens because the value <i>dpar</i> [5] was altered outside of the routine, or the <i>dcg_check</i> routine was not called.
<i>RCI_request</i> =-11	Indicates that the routine was interrupted because it enters the infinite cycle. This usually happens because the values <i>ipar</i> [7], <i>ipar</i> [8], <i>ipar</i> [9] were altered outside of the routine, or the <i>dcg_check</i> routine was not called.
<i>RCI_request</i> = 1	Indicates that you must multiply the matrix by <i>tmp</i> [0: <i>n</i> - 1], put the result in the <i>tmp</i> [<i>n</i> :2* <i>n</i> - 1], and return control back to the routine <i>dcg</i> .
<i>RCI_request</i> = 2	Indicates that you must perform the stopping tests. If they fail, return control back to the <i>dcg</i> routine. Otherwise, the solution is found and stored in the vector <i>x</i> .
<i>RCI_request</i> = 3	Indicates that you must apply the preconditioner to <i>tmp</i> [2* <i>n</i> :3* <i>n</i> - 1], put the result in the <i>tmp</i> [3* <i>n</i> :4* <i>n</i> - 1], and return control back to the routine <i>dcg</i> .

dcgmrhs_get

Retrieves the number of the current iteration.

Syntax

```
void dcgmrhs_get (const MKL_INT *n , const double *x , const MKL_INT *nrhs , const
double *b , const MKL_INT *RCI_request , const MKL_INT *ipar , const double *dpar ,
const double *tmp , MKL_INT *itercount );
```

Include Files

- mkl.h

Description

The routine `dcgmrhs_get` retrieves the current iteration number of the solving process.

Input Parameters

<i>n</i>	Sets the size of the problem.
<i>x</i>	Array of size $n*nrhs$. Contains the initial approximation to the solution vectors.
<i>nrhs</i>	Sets the number of right-hand sides.
<i>b</i>	Array of size $n*nrhs$. Contains the right-hand side .
<i>RCI_request</i>	This parameter is not used.
<i>ipar</i>	Array of size $(128+2*nrhs)$. Refer to the CG Common Parameters .
<i>dpar</i>	Array of size $(128+2*nrhs)$. Refer to the CG Common Parameters .
<i>tmp</i>	Array of size $(n*(3+nrhs))$. Refer to the CG Common Parameters .

Output Parameters

<i>itercount</i>	Array of size <i>nrhs</i> . Returns the current iteration number for each right-hand side.

Return Values

The routine `dcgmrhs_get` has no return values.

dfgmres_init

Initializes the solver.

Syntax

```
void dfgmres_init (const MKL_INT *n , const double *x , const double *b , MKL_INT
*RCI_request , MKL_INT *ipar , double *dpar , double *tmp );
```

Include Files

- mkl.h

Description

The routine `dfgmres_init` initializes the solver. After initialization all subsequent invocations of Intel MKL RCI FGMRES routines use the values of all parameters that are returned by `dfgmres_init`. Advanced users can skip this step and set the values in the *ipar* and *dpar* arrays directly.

WARNING

You can modify the contents of these arrays after they are passed to the solver routine only if you are sure that the values are correct and consistent. You can perform a basic check for correctness and consistency by calling the `dfgmres_check` routine, but it does not guarantee that the method will work correctly.

Input Parameters

n	Sets the size of the problem.
x	Array of size n . Contains the initial approximation to the solution vector. Normally it is equal to 0 or to b .
b	Array of size n . Contains the right-hand side vector.

Output Parameters

$RCI\_request$	Gives information about the result of the routine.
$ipar$	Array of size 128. Refer to the FGMRES Common Parameters .
$dpar$	Array of size 128. Refer to the FGMRES Common Parameters .
tmp	Array of size $((2*ipar[14] + 1)*n + ipar[14]*(ipar[14] + 9)/2 + 1)$. Refer to the FGMRES Common Parameters .

Return Values

$RCI\_request = 0$	Indicates that the task completed normally.
$RCI\_request = -10000$	Indicates failure to complete the task.

dfgmres_check

Checks consistency and correctness of the user defined data.

Syntax

```
void dfgmres_check (const MKL_INT *n, const double *x, const double *b, MKL_INT *RCI_request, MKL_INT *ipar, double *dpar, double *tmp );
```

Include Files

- `mkl.h`

Description

The routine `dfgmres_check` checks consistency and correctness of the parameters to be passed to the solver routine `dfgmres`. However, this operation does not guarantee that the method gives the correct result. It only reduces the chance of making a mistake in the parameters of the routine. Skip this operation only if you are sure that the correct data is specified in the solver parameters.

The lengths of all vectors are assumed to have been defined in a previous call to the `dfgmres_init` routine.

Input Parameters

n	Sets the size of the problem.
x	Array of size n . Contains the initial approximation to the solution vector. Normally it is equal to 0 or to b .
b	Array of size n . Contains the right-hand side vector.

Output Parameters

$RCI\_request$	Gives information about result of the routine.
$ipar$	Array of size 128. Refer to the FGMRES Common Parameters .
$dpar$	Array of size 128. Refer to the FGMRES Common Parameters .
tmp	Array of size $((2*ipar[14] + 1)*n + ipar[14]*(ipar[14] + 9)/2 + 1)$. Refer to the FGMRES Common Parameters .

Return Values

$RCI\_request = 0$	Indicates that the task completed normally.
$RCI\_request = -1100$	Indicates that the task is interrupted and the errors occur.
$RCI\_request = -1001$	Indicates that there are some warning messages.
$RCI\_request = -1010$	Indicates that the routine changed some parameters to make them consistent or correct.
$RCI\_request = -1011$	Indicates that there are some warning messages and that the routine changed some parameters.

dfgmres

Makes the FGMRES iterations.

Syntax

```
void dfgmres (const MKL_INT *n, double *x, double *b, MKL_INT *RCI_request, MKL_INT
*ipar, double *dpar, double *tmp );
```

Include Files

- `mkl.h`

Description

The routine `dfgmres` performs the FGMRES iterations [Saad03], using the value that was in the array x before the first call as an initial approximation of the solution vector. To update the current approximation to the solution, the `dfgmres_get` routine must be called. The RCI FGMRES iterations can be continued after the call to the `dfgmres_get` routine only if the value of the parameter $ipar[12]$ is not equal to 0 (default value). Note that the updated solution overwrites the right-hand side in the vector b if the parameter $ipar[12]$ is positive, and the restarted version of the FGMRES method can not be run. If you want to keep the right-hand side, you must save it in a different memory location before the first call to the `dfgmres_get` routine with a positive $ipar[12]$.

The parameter *RCI_request* gives information about the task completion and requests results of certain operations that the solver requires.

The lengths of all the vectors must be defined in a previous call to the *dfgmres_init* routine.

Input Parameters

<i>n</i>	Sets the size of the problem.
<i>x</i>	Array of size <i>n</i> . Contains the initial approximation to the solution vector.
<i>b</i>	Array of size <i>n</i> . Contains the right-hand side vector.
<i>tmp</i>	Array of size [12]. Refer to the FGMRES Common Parameters .

Output Parameters

<i>RCI_request</i>	Informs about result of work of the routine.
<i>ipar</i>	Array of size 128. Refer to the FGMRES Common Parameters .
<i>dpar</i>	Array of size 128. Refer to the FGMRES Common Parameters .
<i>tmp</i>	Array of size $((2 * ipar(15) + 1) * n + ipar(15) * ipar(15) + 9) / 2 + 1$. Refer to the FGMRES Common Parameters .

Return Values

<i>RCI_request</i> =0	Indicates that the task completed normally and the solution is found and stored in the vector <i>x</i> . This occurs only if the stopping tests are fully automatic. For the user defined stopping tests, see the description of the <i>RCI_request</i> = 2 or 4.
<i>RCI_request</i> =-1	Indicates that the routine was interrupted because the maximum number of iterations was reached, but the relative stopping criterion was not met. This situation occurs only if you request both tests.
<i>RCI_request</i> = -10	Indicates that the routine was interrupted because of an attempt to divide by zero. Usually this happens if the matrix is degenerate or almost degenerate. However, it may happen if the parameter <i>dpar</i> is altered, or if the method is not stopped when the solution is found.
<i>RCI_request</i> = -11	Indicates that the routine was interrupted because it entered an infinite cycle. Usually this happens because the values <i>ipar</i> [7], <i>ipar</i> [8], <i>ipar</i> [9] were altered outside of the routine, or the <i>dfgmres_check</i> routine was not called.
<i>RCI_request</i> = -12	Indicates that the routine was interrupted because errors were found in the method parameters. Usually this happens if the parameters <i>ipar</i> and <i>dpar</i> were altered by mistake outside the routine.

<code>RCI_request= 1</code>	Indicates that you must multiply the matrix by <code>tmp[ipar[21] - 1:ipar[21] + n - 2]</code> , put the result in the <code>tmp[ipar[22] - 1:ipar[22] + n - 2]</code> , and return control back to the routine <code>dfgmres</code> .
<code>RCI_request= 2</code>	Indicates that you must perform the stopping tests. If they fail, return control to the <code>dfgmres</code> routine. Otherwise, the FGMRES solution is found, and you can run the <code>fgmres_get</code> routine to update the computed solution in the vector <code>x</code> .
<code>RCI_request= 3</code>	Indicates that you must apply the inverse preconditioner to <code>tmp[ipar[21] - 1:ipar[21] + n - 2]</code> , put the result in the <code>tmp[ipar[22] - 1:ipar[22] + n - 2]</code> , and return control back to the routine <code>dfgmres</code> .
<code>RCI_request= 4</code>	Indicates that you must check the norm of the currently generated vector. If it is not zero within the computational/rounding errors, return control to the <code>dfgmres</code> routine. Otherwise, the FGMRES solution is found, and you can run the <code>dfgmres_get</code> routine to update the computed solution in the vector <code>x</code> .

dfgmres_get

Retrieves the number of the current iteration and updates the solution.

Syntax

```
void dfgmres_get (const MKL_INT *n, double *x, double *b, MKL_INT *RCI_request, const
MKL_INT *ipar, const double *dpar, double *tmp, MKL_INT *itercount );
```

Include Files

- `mkl.h`

Description

The routine `dfgmres_get` retrieves the current iteration number of the solution process and updates the solution according to the computations performed by the `dfgmres` routine. To retrieve the current iteration number only, set the parameter `ipar[12] = -1` beforehand. Normally, you should do this before proceeding further with the computations. If the intermediate solution is needed, the method parameters must be set properly. For details see [FGMRES Common Parameters](#) and the Iterative Sparse Solver code examples in the Intel MKL installation directory:

- `examples/solverc/source`

Input Parameters

<code>n</code>	Sets the size of the problem.
<code>ipar</code>	Array of size 128. Refer to the FGMRES Common Parameters .
<code>dpar</code>	Array of size 128. Refer to the FGMRES Common Parameters .

tmp Array of size $((2 * ipar[14] + 1) * n + ipar[14] * ipar[14] + 9) / 2 + 1$. Refer to the [FGMRES Common Parameters](#).

Output Parameters

x Array of size n . If $ipar[12] = 0$, it contains the updated approximation to the solution according to the computations done in `dfgmres` routine. Otherwise, it is not changed.

b Array of size n . If $ipar(13) > 0$, it contains the updated approximation to the solution according to the computations done in `dfgmres` routine. Otherwise, it is not changed.

RCI_request Gives information about result of the routine.

itercount Contains the value of the current iteration number.

Return Values

RCI_request = 0 Indicates that the task completed normally.

RCI_request = -12 Indicates that the routine was interrupted because errors were found in the routine parameters. Usually this happens if the parameters *ipar* and *dpar* were altered by mistake outside of the routine.

RCI_request = -10000 Indicates that the routine failed to complete the task.

Implementation Details

Several aspects of the Intel MKL RCI ISS interface are platform-specific and language-specific. To promote portability across platforms and ease of use across different languages, include one of the Intel MKL RCI ISS language-specific header files.

NOTE

Intel MKL does not support the RCI ISS interface unless you include the language-specific header file.

Preconditioners based on Incomplete LU Factorization Technique

Preconditioners, or accelerators are used to accelerate an iterative solution process. In some cases, their use can reduce the number of iterations dramatically and thus lead to better solver performance. Although the terms *preconditioner* and *accelerator* are synonyms, hereafter only *preconditioner* is used.

Intel MKL provides two preconditioners, ILU0 and ILUT, for sparse matrices presented in the format accepted in the Intel MKL direct sparse solvers (three-array variation of the CSR storage format described in [Sparse Matrix Storage Format](#)). The algorithms used are described in [[Saad03](#)].

The ILU0 preconditioner is based on a well-known factorization of the original matrix into a product of two triangular matrices: lower and upper triangular matrices. Usually, such decomposition leads to some fill-in in the resulting matrix structure in comparison with the original matrix. The distinctive feature of the ILU0 preconditioner is that it preserves the structure of the original matrix in the result.

Unlike the ILU0 preconditioner, the ILUT preconditioner preserves some resulting fill-in in the preconditioner matrix structure. The distinctive feature of the ILUT algorithm is that it calculates each element of the preconditioner and saves each one if it satisfies two conditions simultaneously: its value is greater than the product of the given tolerance and matrix row norm, and its value is in the given bandwidth of the resulting preconditioner matrix.

Both ILU0 and ILUT preconditioners can apply to any non-degenerate matrix. They can be used alone or together with the Intel MKL RCI FGMRES solver (see [Sparse Solver Routines](#)). Avoid using these preconditioners with MKL RCI CG solver because in general, they produce a non-symmetric resulting matrix even if the original matrix is symmetric. Usually, an inverse of the preconditioner is required in this case. To do this the Intel MKL triangular solver routine `mkl_dcsrtrsv` must be applied twice: for the lower triangular part of the preconditioner, and then for its upper triangular part.

NOTE

Although ILU0 and ILUT preconditioners apply to any non-degenerate matrix, in some cases the algorithm may fail to ensure successful termination and the required result. Whether or not the preconditioner produces an acceptable result can only be determined in practice.

A preconditioner may increase the number of iterations for an arbitrary case of the system and the initial solution, and even ruin the convergence. It is your responsibility as a user to choose a suitable preconditioner.

General Scheme of Using ILUT and RCI FGMRES Routines

The general scheme for use is the same for both preconditioners. Some differences exist in the calling parameters of the preconditioners and in the subsequent call of two triangular solvers. You can see all these differences in the preconditioner code examples (`dcsrilu*.*`) in the `examples` folder of the Intel MKL installation directory:

- `examples/solverc/source`

ILU0 and ILUT Preconditioners Interface Description

The concepts required to understand the use of the Intel MKL preconditioner routines are discussed in the [Appendix A Linear Solvers Basics](#).

User Data Arrays

The preconditioner routines take arrays of user data as input. To minimize storage requirements and improve overall run-time efficiency, the Intel MKL preconditioner routines do not make copies of the user input arrays.

Common Parameters

Some parameters of the preconditioners are common with the [FGMRES Common Parameters](#). The routine `dfgmres_init` specifies their default and initial values. However, some parameters can be redefined with other values. These parameters are listed below.

For the ILU0 preconditioner:

`ipar[1]` - specifies the destination of error messages generated by the ILU0 routine. The default value 6 means that all error messages are displayed on the screen. Otherwise routine creates a log file called `MKL_PREC_log.txt` and writes error messages to it. Note if the parameter `ipar[5]` is set to 0, then error messages are not generated at all.

`ipar[5]` - specifies whether error messages are generated. If its value is not equal to 0, the ILU0 routine returns error messages as specified by the parameter `ipar[1]`. Otherwise, the routine does not generate error messages at all, but returns a negative value for the parameter `ierr`. The default value is 1.

For the ILUT preconditioner:

ipar[1] - specifies the destination of error messages generated by the ILUT routine. The default value 6 means that all messages are displayed on the screen. Otherwise routine creates a log file called `MKL_PREC_log.txt` and writes error messages to it. Note if the parameter *ipar[5]* is set to 0, then error messages are not generated at all.

ipar[5] - specifies whether error messages are generated. If its value is not equal to 0, the ILUT routine returns error messages as specified by the parameter *ipar[1]*. Otherwise, the routine does not generate error messages at all, but returns a negative value for the parameter *ierr*. The default value is 1.

ipar[6] - if its value is greater than 0, the ILUT routine generates warning messages as specified by the parameter *ipar[1]* and continues calculations. If its value is equal to 0, the routine returns a positive value of the parameter *ierr*. If its value is less than 0, the routine generates a warning message as specified by the parameter *ipar[1]* and returns a positive value of the parameter *ierr*. The default value is 1.

dcsrilu0

ILU0 preconditioner based on incomplete LU factorization of a sparse matrix.

Syntax

```
void dcsrilu0 (const MKL_INT *n , const double *a , const MKL_INT *ia , const MKL_INT *ja , double *bilu0 , const MKL_INT *ipar , const double *dpar , MKL_INT *ierr );
```

Include Files

- `mkl.h`

Description

The routine `dcsrilu0` computes a preconditioner B [Saad03] of a given sparse matrix A stored in the format accepted in the direct sparse solvers:

$A \sim B = L * U$, where L is a lower triangular matrix with a unit diagonal, U is an upper triangular matrix with a non-unit diagonal, and the portrait of the original matrix A is used to store the incomplete factors L and U .

CAUTION

This routine supports only one-based indexing of the array parameters.

Input Parameters

<i>n</i>	Size (number of rows or columns) of the original square n -by- n matrix A .
<i>a</i>	Array containing the set of elements of the matrix A . Its length is equal to the number of non-zero elements in the matrix A . Refer to the <i>values</i> array description in the Sparse Matrix Storage Format for more details.
<i>ia</i>	Array of size $(n+1)$ containing begin indices of rows of the matrix A such that <i>ia[i]</i> is the index in the array <i>a</i> of the first non-zero element from the row <i>i</i> . The value of the last element <i>ia[n]</i> is equal to the number of non-zero elements in the matrix A , plus one. Refer to the <i>rowIndex</i> array description in the Sparse Matrix Storage Format for more details.
<i>ja</i>	Array containing the column indices for each non-zero element of the matrix A . It is important that the indices are in increasing order per row. The matrix size is equal to the size of the array <i>a</i> . Refer to the <i>columns</i> array description in the Sparse Matrix Storage Format for more details.

CAUTION

If column indices are not stored in ascending order for each row of matrix, the result of the routine might not be correct.

ipar

Array of size 128. This parameter specifies the integer set of data for both the ILU0 and RCI FGMRES computations. Refer to the *ipar* array description in the [FGMRES Common Parameters](#) for more details on FGMRES parameter entries. The entries that are specific to ILU0 are listed below.

ipar[30]

specifies how the routine operates when a zero diagonal element occurs during calculation. If this parameter is set to 0 (the default value set by the routine [dfgmres_init](#)), then the calculations are stopped and the routine returns a non-zero error value. Otherwise, the diagonal element is set to the value of *dpar*[31] and the calculations continue.

NOTE

You can declare the *ipar* array with a size of 32. However, for future compatibility you must declare the array *ipar* with length 128.

dpar

Array of size 128. This parameter specifies the double precision set of data for both the ILU0 and RCI FGMRES computations. Refer to the *dpar* array description in the [FGMRES Common Parameters](#) for more details on FGMRES parameter entries. The entries specific to ILU0 are listed below.

dpar[30]

specifies a small value, which is compared with the computed diagonal elements. When *ipar*[30] is not 0, then diagonal elements less than *dpar*[30] are set to *dpar*[31]. The default value is 1.0e-16.

NOTE

This parameter can be set to the negative value, because the calculation uses its absolute value.

If this parameter is set to 0, the comparison with the diagonal element is not performed.

dpar[31]

specifies the value that is assigned to the diagonal element if its value is less than *dpar*[30] (see above). The default value is 1.0e-10.

NOTE

You can declare the *dpar* array with a size of 32. However, for future compatibility you must declare the array *dpar* with length 128.

Output Parameters

<i>bilu0</i>	Array <i>B</i> containing non-zero elements of the resulting preconditioning matrix <i>B</i> , stored in the format accepted in direct sparse solvers. Its size is equal to the number of non-zero elements in the matrix <i>A</i> . Refer to the <i>values</i> array description in the Sparse Matrix Storage Format section for more details.
<i>ierr</i>	Error flag, gives information about the routine completion.

NOTE

To present the resulting preconditioning matrix in the CSR3 format the arrays *ia* (row indices) and *ja* (column indices) of the input matrix must be used.

Return Values

<i>ierr</i> =0	Indicates that the task completed normally.
<i>ierr</i> =-101	Indicates that the routine was interrupted and that error occurred: at least one diagonal element is omitted from the matrix in CSR3 format (see Sparse Matrix Storage Format).
<i>ierr</i> =-102	Indicates that the routine was interrupted because the matrix contains a diagonal element with the value of zero.
<i>ierr</i> =-103	Indicates that the routine was interrupted because the matrix contains a diagonal element which is so small that it could cause an overflow, or that it would cause a bad approximation to ILU0.
<i>ierr</i> =-104	Indicates that the routine was interrupted because the memory is insufficient for the internal work array.
<i>ierr</i> =-105	Indicates that the routine was interrupted because the input matrix size <i>n</i> is less than or equal to 0.
<i>ierr</i> =-106	Indicates that the routine was interrupted because the column indices <i>ja</i> are not in the ascending order.

dcsrilit

ILUT preconditioner based on the incomplete LU factorization with a threshold of a sparse matrix.

Syntax

```
void dcsrilit (const MKL_INT *n, const double *a, const MKL_INT *ia, const MKL_INT *ja,
double *bilut, MKL_INT *ibilut, MKL_INT *jbilut, const double *tol, const MKL_INT
*maxfil, const MKL_INT *ipar, const double *dpar, MKL_INT *ierr);
```

Include Files

- mkl.h

Description

The routine `dcsrilut` computes a preconditioner B [Saad03] of a given sparse matrix A stored in the format accepted in the direct sparse solvers:

$A \sim B = L^* U$, where L is a lower triangular matrix with unit diagonal and U is an upper triangular matrix with non-unit diagonal.

The following threshold criteria are used to generate the incomplete factors L and U :

- 1) the resulting entry must be greater than the matrix current row norm multiplied by the parameter `tol`, and
- 2) the number of the non-zero elements in each row of the resulting L and U factors must not be greater than the value of the parameter `maxfil`.

CAUTION

This routine supports only one-based indexing of the array parameters.

Input Parameters

<code>n</code>	Size (number of rows or columns) of the original square n -by- n matrix A .
<code>a</code>	Array containing all non-zero elements of the matrix A . The length of the array is equal to their number. Refer to <code>values</code> array description in the Sparse Matrix Storage Format section for more details.
<code>ia</code>	Array of size $(n+1)$ containing indices of non-zero elements in the array a . <code>ia[i]</code> is the index of the first non-zero element from the row i . The value of the last element <code>ia[n]</code> is equal to the number of non-zeros in the matrix A , plus one. Refer to the <code>rowIndex</code> array description in the Sparse Matrix Storage Format for more details.
<code>ja</code>	Array of size equal to the size of the array a . This array contains the column numbers for each non-zero element of the matrix A . It is important that the indices are in increasing order per row. Refer to the <code>columns</code> array description in the Sparse Matrix Storage Format for more details.

CAUTION

If column indices are not stored in ascending order for each row of matrix, the result of the routine might not be correct.

<code>tol</code>	Tolerance for threshold criterion for the resulting entries of the preconditioner.
<code>maxfil</code>	Maximum fill-in, which is half of the preconditioner bandwidth. The number of non-zero elements in the rows of the preconditioner cannot exceed $(2 * \text{maxfil} + 1)$.
<code>ipar</code>	Array of size 128. This parameter is used to specify the integer set of data for both the ILUT and RCI FGMRES computations. Refer to the <code>ipar</code> array description in the FGMRES Common Parameters for more details on FGMRES parameter entries. The entries specific to ILUT are listed below.

ipar[30]

specifies how the routine operates if the value of the computed diagonal element is less than the current matrix row norm multiplied by the value of the parameter *tol*. If *ipar*[30] = 0, then the calculation is stopped and the routine returns non-zero error value. Otherwise, the value of the diagonal element is set to a value determined by *dpar*[30] (see its description below), and the calculations continue.

NOTE

There is no default value for *ipar*[30] even if the preconditioner is used within the RCI ISS context. Always set the value of this entry.

NOTE

You must declare the array *ipar* with length 128. While defining the array in the code as *ipar*[30] works, there is no guarantee of future compatibility with Intel MKL.

dpar

Array of size 128. This parameter specifies the double precision set of data for both ILUT and RCI FGMRES computations. Refer to the *dpar* array description in the [FGMRES Common Parameters](#) for more details on FGMRES parameter entries. The entries that are specific to ILUT are listed below.

dpar[30]

used to adjust the value of small diagonal elements. Diagonal elements with a value less than the current matrix row norm multiplied by *tol* are replaced with the value of *dpar*[30] multiplied by the matrix row norm.

NOTE

There is no default value for *dpar*[30] entry even if the preconditioner is used within RCI ISS context. Always set the value of this entry.

NOTE

You must declare the array *dpar* with length 128. While defining the array in the code as *ipar*[30] works, there is no guarantee of future compatibility with Intel MKL.

Output Parameters

<i>bilut</i>	Array containing non-zero elements of the resulting preconditioning matrix <i>B</i> , stored in the format accepted in the direct sparse solvers. Refer to the <i>values</i> array description in the Sparse Matrix Storage Format for more details. The size of the array is equal to $(2*maxfil+1)*n-maxfil*(maxfil+1)+1$.
NOTE Provide enough memory for this array before calling the routine. Otherwise, the routine may fail to complete successfully with a correct result.	
<i>ibilut</i>	Array of size $(n+1)$ containing indices of non-zero elements in the array <i>bilut</i> . <i>ibilut</i> [<i>i</i>] is the index of the first non-zero element from the row <i>i</i> . The value of the last element <i>ibilut</i> [<i>n</i>] is equal to the number of non-zeros in the matrix <i>B</i> , plus one. Refer to the <i>rowIndex</i> array description in the Sparse Matrix Storage Format for more details.
<i>jbilut</i>	Array, its size is equal to the size of the array <i>bilut</i> . This array contains the column numbers for each non-zero element of the matrix <i>B</i> . Refer to the <i>columns</i> array description in the Sparse Matrix Storage Format for more details.
<i>ierr</i>	Error flag, gives information about the routine completion.

Return Values

<i>ierr</i> =0	Indicates that the task completed normally.
<i>ierr</i> =-101	Indicates that the routine was interrupted because of an error: the number of elements in some matrix row specified in the sparse format is equal to or less than 0.
<i>ierr</i> =-102	Indicates that the routine was interrupted because the value of the computed diagonal element is less than the product of the given tolerance and the current matrix row norm, and it cannot be replaced as <i>ipar</i> [30]=0.
<i>ierr</i> =-103	Indicates that the routine was interrupted because the element <i>ia</i> [<i>i</i>] is less than or equal to the element <i>ia</i> [<i>i</i> - 1] (see Sparse Matrix Storage Format).
<i>ierr</i> =-104	Indicates that the routine was interrupted because the memory is insufficient for the internal work arrays.
<i>ierr</i> =-105	Indicates that the routine was interrupted because the input value of <i>maxfil</i> is less than 0.
<i>ierr</i> =-106	Indicates that the routine was interrupted because the size <i>n</i> of the input matrix is less than 0.

<code>ierr=-107</code>	Indicates that the routine was interrupted because an element of the array <code>ja</code> is less than 1, or greater than <code>n</code> (see Sparse Matrix Storage Format).
<code>ierr=101</code>	The value of <code>maxfil</code> is greater than or equal to <code>n</code> . The calculation is performed with the value of <code>maxfil</code> set to <code>(n-1)</code> .
<code>ierr=102</code>	The value of <code>tol</code> is less than 0. The calculation is performed with the value of the parameter set to <code>(-tol)</code> .
<code>ierr=103</code>	The absolute value of <code>tol</code> is greater than value of <code>dpar[30]</code> ; it can result in instability of the calculation.
<code>ierr=104</code>	The value of <code>dpar[30]</code> is equal to 0. It can cause calculations to fail.

Sparse Matrix Checker Routines

Intel MKL provides a sparse matrix checker so that you can find errors in the storage of sparse matrices before calling Intel MKL PARDISO, DSS, or Sparse BLAS routines.

`sparse_matrix_checker`

Checks correctness of sparse matrix.

Syntax

```
MKL_INT sparse_matrix_checker (sparse_struct* handle);
```

Include Files

- `mkl.h`

Description

The `sparse_matrix_checker` routine checks a user-defined array used to store a sparse matrix in order to detect issues which could cause problems in routines that require sparse input matrices, such as Intel MKL PARDISO, DSS, or Sparse BLAS.

Input Parameters

`handle` Pointer to the data structure describing the sparse array to check.

Return Values

The routine returns a value `error`. Additionally, the `check_result` parameter returns information about where the error occurred, which can be used when `message_level` is `MKL_NO_PRINT`.

Sparse Matrix Checker Error Values

<code>error</code> value	Meaning	Location
<code>MKL_SPARSE_CHECKER_SUCCESS</code>	The input array successfully passed all checks.	

<i>error value</i>	Meaning	Location
MKL_SPARSE_CHECKER_NON_MONOTONIC	The input array is not 0 or 1 based (<i>ia</i> [0] is not 0 or 1) or elements of <i>ia</i> are not in non-decreasing order as required.	C: <i>ia</i> [<i>i</i>] and <i>ia</i> [<i>i</i> + 1] are incompatible. <i>check_result</i> [0] = <i>i</i> <i>check_result</i> [1] = <i>ia</i> [<i>i</i>] <i>check_result</i> [2] = <i>ia</i> [<i>i</i> + 1]
MKL_SPARSE_CHECKER_OUT_OF_RANGE	The value of the <i>ja</i> array is lower than the number of the first column or greater than the number of the last column.	C: <i>ia</i> [<i>i</i>] and <i>ia</i> [<i>i</i> + 1] are incompatible. <i>check_result</i> [0] = <i>i</i> <i>check_result</i> [1] = <i>ia</i> [<i>i</i>] <i>check_result</i> [2] = <i>ia</i> [<i>i</i> + 1]
MKL_SPARSE_CHECKER_NON_TRIANGULAR	The <i>matrix_structure</i> parameter is MKL_UPPER_TRIANGULAR and both <i>ia</i> and <i>ja</i> are not upper triangular, or the <i>matrix_structure</i> parameter is MKL_LOWER_TRIANGULAR and both <i>ia</i> and <i>ja</i> are not lower triangular	C: <i>ia</i> [<i>i</i>] and <i>ja</i> [<i>j</i>] are incompatible. <i>check_result</i> [0] = <i>i</i> <i>check_result</i> [1] = <i>ia</i> [<i>i</i>] = <i>j</i> <i>check_result</i> [2] = <i>ja</i> [<i>j</i>]
MKL_SPARSE_CHECKER_NON_ORDERED	The elements of the <i>ja</i> array are not in non-decreasing order in each row as required.	C: <i>ia</i> [<i>i</i>] and <i>ia</i> [<i>i</i> + 1] are incompatible. <i>check_result</i> [0] = <i>j</i> <i>check_result</i> [1] = <i>ja</i> [<i>j</i>] <i>check_result</i> [2] = <i>ja</i> [<i>j</i> + 1]

sparse_matrix_init

Initializes handle for sparse matrix checker.

Syntax

```
void sparse_matrix_init (sparse_struct* handle);
```

Include Files

- mkl.h

Description

The `sparse_matrix_init` routine initializes the handle for the `sparse_matrix_checker` routine. The `handle` variable contains this data:

Description of `sparse_matrix_checker` *handle* Data

Field	Type	Possible Values	Meaning
<code>n</code>	<code>MKL_INT</code>		Order of the matrix stored in sparse array.
<code>csr_ia</code>	<code>MKL_INT*</code>	Pointer to <code>ia</code> array for <code>matrix_format = MKL_CSR</code>	
<code>csr_ja</code>	<code>MKL_INT*</code>	Pointer to <code>ja</code> array for <code>matrix_format = MKL_CSR</code>	
<code>check_result[3]</code>	<code>MKL_INT</code>	See Sparse Matrix Checker Error Values for a description of the values returned in <code>check_result</code> .	Indicates location of problem in array when <code>message_level = MKL_NO_PRINT</code> .
<code>indexing</code>	<code>sparse_matrix_indexing</code>	<code>MKL_ZERO_BASED</code> <code>MKL_ONE_BASED</code>	Indexing style used in array.
<code>matrix_structure</code>	<code>sparse_matrix_structures</code>	<code>MKL_GENERAL_STRUCTURE</code> <code>MKL_UPPER_TRIANGULAR</code> <code>MKL_LOWER_TRIANGULAR</code> <code>MKL_STRUCTURAL_SYMMETRIC</code>	Type of sparse matrix stored in array.
<code>matrix_format</code>	<code>sparse_matrix_formats</code>	<code>MKL_CSR</code>	Format of array used for sparse matrix storage.
<code>message_level</code>	<code>sparse_matrix_message_levels</code>	<code>MKL_NO_PRINT</code> <code>MKL_PRINT</code>	Determines whether or not feedback is provided on the screen.
<code>print_style</code>	<code>sparse_matrix_print_styles</code>	<code>MKL_C_STYLE</code> <code>MKL_FORTRAN_STYLE</code>	Determines style of messages when <code>message_level = MKL_PRINT</code> .

Input Parameters

handle Pointer to the data structure describing the sparse array to check.

Output Parameters

handle Pointer to the initialized data structure.

Extended Eigensolver Routines

The Extended Eigensolver functionality in Intel Math Kernel Library (Intel MKL) is based on the FEAST Eigenvalue Solver 2.0 (<http://www.ecs.umass.edu/~polizzi/feast>) in compliance with a BSD license agreement.

Extended Eigensolver uses the same naming convention as the original FEAST package.

NOTE

Intel MKL only supports the shared memory programming (SMP) version of the eigenvalue solver.

- [The FEAST Algorithm](#) gives a brief description of the algorithm underlying the Extended Eigensolver.
- [Extended Eigensolver Functionality](#) describes the problems that can and cannot be solved with the Extended Eigensolver and how to get the best results from the routines.
- [Extended Eigensolver Interfaces](#) gives a reference for calling Extended Eigensolver routines.

The FEAST Algorithm

The Extended Eigensolver functionality is a set of high-performance numerical routines for solving symmetric standard eigenvalue problems, $Ax=\lambda x$, or generalized symmetric-definite eigenvalue problems, $Ax=\lambda Bx$. It yields all the eigenvalues (λ) and eigenvectors (x) within a given search interval $[\lambda_{\min}, \lambda_{\max}]$. It is based on the FEAST algorithm, an innovative fast and stable numerical algorithm presented in [Polizzi09], which fundamentally differs from the traditional Krylov subspace iteration based techniques (Arnoldi and Lanczos algorithms [Bai00]) or other Davidson-Jacobi techniques [Sleijpen96]. The FEAST algorithm is inspired by the density-matrix representation and contour integration techniques in quantum mechanics.

The FEAST numerical algorithm obtains eigenpair solutions using a numerically efficient contour integration technique. The main computational tasks in the FEAST algorithm consist of solving a few independent linear systems along the contour and solving a reduced eigenvalue problem. Consider a circle centered in the middle of the search interval $[\lambda_{\min}, \lambda_{\max}]$. The numerical integration over the circle in the current version of FEAST is performed using N_e -point Gauss-Legendre quadrature with x_e the e -th Gauss node associated with the weight ω_e . For example, for the case $N_e = 8$:

```
(  $x_1, \omega_1$  ) = (0.183434642495649 , 0.362683783378361),
(  $x_2, \omega_2$  ) = (-0.183434642495649 , 0.362683783378361),
(  $x_3, \omega_3$  ) = (0.525532409916328 , 0.313706645877887),
(  $x_4, \omega_4$  ) = (-0.525532409916328 , 0.313706645877887),
(  $x_5, \omega_5$  ) = (0.796666477413626 , 0.222381034453374),
(  $x_6, \omega_6$  ) = (-0.796666477413626 , 0.222381034453374),
(  $x_7, \omega_7$  ) = (0.960289856497536 , 0.101228536290376), and
(  $x_8, \omega_8$  ) = (-0.960289856497536 , 0.101228536290376).
```

The figure [FEAST Pseudocode](#) shows the basic pseudocode for the FEAST algorithm for the case of real symmetric (left pane) and complex Hermitian (right pane) generalized eigenvalue problems, using N for the size of the system and M for the number of eigenvalues in the search interval (see [Polizzi09]).

NOTE

The pseudocode presents a simplified version of the actual algorithm. Refer to <http://arxiv.org/abs/1302.0432> for an in-depth presentation and mathematical proof of convergence of FEAST.

FEAST Pseudocode

A: real symmetric
B: symmetric positive definite (SPD)
 $\Re\{x\}$: real part of x

1. Select $M_0 > M$ random vectors $Y_{N \times M_0} \in \mathbb{R}^{N \times M_0}$.
2. Set $Q = 0$ with $Q \in \mathbb{R}^{N \times M_0}$; $r = (\lambda_{\max} - \lambda_{\min}) / 2$;
For $e = 1, \dots, N_e$
compute $\theta_e = -(\pi / 2)(x_e - 1)$,
compute $Z_e = (\lambda_{\max} + \lambda_{\min}) / 2 + r \exp(i\theta_e)$,
solve $(Z_e B - A)Q_e = Y$ to obtain $Q_e \in \mathbb{C}^{N \times M_0}$
compute $Q = Q - (\omega_e / 2) \Re\{r \exp(i\theta_e) Q_e\}$
End
3. Form $A_{Q_{M_0 \times M_0}} = Q^T A Q$ and $B_{Q_{M_0 \times M_0}} = Q^T B Q$
reduce value of M_0 if B_Q is not symmetric
positive definite.
4. Solve $A_Q \Phi = \varepsilon B_Q \Phi$ to obtain the M_0 eigenvalue
 ε_m , and eigenvectors $\Phi_{M_0 \times M_0} \in \mathbb{R}^{M_0 \times M_0}$.
5. Set $\lambda_m = \varepsilon_m$ and compute $X_{N \times M_0} = Q_{N \times M_0} \Phi_{M_0 \times M_0}$.
If $\lambda_m \in [\lambda_{\min}, \lambda_{\max}]$, λ_m is an eigenvalue solution
and its eigenvector is X_m (the m -th column of X).
6. Check convergence for the trace of the
eigenvalues λ_m . If iterative refinement is
needed, compute $Y = BX$ and go back to step 2.

A: complex Hermitian
B: Hermitian positive definite (HPD)

1. Select $M_0 > M$ random vectors $Y_{N \times M_0} \in \mathbb{C}^{N \times M_0}$.
2. Set $Q = 0$ with $Q \in \mathbb{R}^{N \times M_0}$; $r = (\lambda_{\max} - \lambda_{\min}) / 2$;
For $e = 1, \dots, N_e$
compute $\theta_e = -(\pi / 2)(x_e - 1)$,
compute $Z_e = (\lambda_{\max} + \lambda_{\min}) / 2 + r \exp(i\theta_e)$,
solve $(Z_e B - A)Q_e = Y$ to obtain $Q_e \in \mathbb{C}^{N \times M_0}$
solve $(Z_e B - A)^H \hat{Q}_e = Y$ to obtain $\hat{Q}_e \in \mathbb{C}^{N \times M_0}$
 $Q = Q - (\omega_e / 4) r (\exp(i\theta_e) Q_e + \exp(-i\theta_e) \hat{Q}_e)$
End
3. Form $A_{Q_{M_0 \times M_0}} = Q^H A Q$ and $B_{Q_{M_0 \times M_0}} = Q^H B Q$
reduce value of M_0 if B_Q is not Hermitian
positive definite.
4. Solve $A_Q \Phi = \varepsilon B_Q \Phi$ to obtain the M_0 eigenvalue
 ε_m , and eigenvectors $\Phi_{M_0 \times M_0} \in \mathbb{C}^{M_0 \times M_0}$.
5. Set $\lambda_m = \varepsilon_m$ and compute $X_{N \times M_0} = Q_{N \times M_0} \Phi_{M_0 \times M_0}$.
If $\lambda_m \in [\lambda_{\min}, \lambda_{\max}]$, λ_m is an eigenvalue solution
and its eigenvector is X_m (the m -th column of X).
6. Check convergence for the trace of the
eigenvalues λ_m . If iterative refinement is
needed, compute $Y = BX$ and go back to step 2.

Extended Eigensolver Functionality

Use Extended Eigensolver to compute all the eigenvalues and eigenvectors within a given search interval.

The eigenvalue problems covered are as follows:

- standard, $Ax = \lambda x$
 - A complex Hermitian
 - A real symmetric
- generalized, $Ax = \lambda Bx$
 - A complex Hermitian, B Hermitian positive definite (hpd)
 - A real symmetric and B real symmetric positive definite (spd)

The Extended Eigensolver functionality offers:

- Real/Complex and Single/Double precisions: double precision is recommended to provide better accuracy of eigenpairs.
- Reverse communication interfaces (RCI) provide maximum flexibility for specific applications. RCI are independent of matrix format and inner system solvers, so you must provide your own linear system solvers (direct or iterative) and matrix-matrix multiply routines.
- Predefined driver interfaces for dense, LAPACK banded, and sparse (CSR) formats are less flexible but are optimized and easy to use:
 - The Extended Eigensolver interfaces for dense matrices are likely to be slower than the comparable LAPACK routines because the FEAST algorithm has a higher computational cost.

- The Extended Eigensolver interfaces for banded matrices support banded LAPACK-type storage.
- The Extended Eigensolver sparse interfaces support compressed sparse row format and use the Intel MKL PARDISO solver.

Optimization Notice

These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Parallelism in Extended Eigensolver Routines

How you achieve parallelism in Extended Eigensolver routines depends on which interface you use. Parallelism (via shared memory programming) is not *explicitly* implemented in Extended Eigensolver routines within one node: the inner linear systems are currently solved one after another.

- Using the Extended Eigensolver RCI interfaces, you can achieve parallelism by providing a threaded inner system solver and a matrix-matrix multiplication routine. When using the RCI interfaces, you are responsible for activating the threaded capabilities of your BLAS and LAPACK libraries most likely using the shell variable `OMP_NUM_THREADS`.
- Using the predefined Extended Eigensolver interfaces, parallelism can be implicitly obtained within the shared memory version of BLAS, LAPACK or Intel MKL PARDISO. The shell variable `MKL_NUM_THREADS` can be used for automatically setting the number of OpenMP threads (cores) for BLAS, LAPACK, and Intel MKL PARDISO.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Achieving Performance With Extended Eigensolver Routines

In order to use the Extended Eigensolver Routines, you need to provide

- the search interval and the size of the subspace M_0 (overestimation of the number of eigenvalues M within a given search interval);
- the system matrix in dense, banded, or sparse CSR format if the Extended Eigensolver predefined interfaces are used, or a high-performance complex direct or iterative system solver and matrix-vector multiplication routine if RCI interfaces are used.

In return, you can expect

- fast convergence with very high accuracy when seeking up to 1000 eigenpairs (in two to four iterations using $M_0 = 1.5M$, and $N_e = 8$ or at most using $N_e = 16$ contour points);
- an extremely robust approach.

The performance of the basic FEAST algorithm depends on a trade-off between the choices of the number of Gauss quadrature points N_e , the size of the subspace M_0 , and the number of outer refinement loops to reach the desired accuracy. In practice you should use $M_0 > 1.5 M$, $N_e = 8$, and at most two refinement loops.

For better performance:

- M_0 should be much smaller than the size of the eigenvalue problem, so that the arithmetic complexity depends mainly on the inner system solver ($O(NM)$ for narrow-banded or sparse systems).
- Parallel scalability performance depends on the shared memory capabilities of the of the inner system solver.
- For very large sparse and challenging systems, application users should make use of the Extended Eigensolver RCI interfaces with customized highly-efficient iterative systems solvers and preconditioners.
- For the Extended Eigensolver interfaces for banded matrices, the parallel performance scalability is limited.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Extended Eigensolver Interfaces

Extended Eigensolver Naming Conventions

There are two different types of interfaces available in the Extended Eigensolver routines:

1. The reverse communication interfaces (RCI):

```
?feast_<matrix type>_rci
```

These interfaces are matrix free format (the interfaces are independent of the matrix data formats). You must provide matrix-vector multiply and direct/iterative linear system solvers for your own explicit or implicit data format.

2. The predefined interfaces:

```
?feast_<matrix type><type of eigenvalue problem>
```

are predefined drivers for `?feast` reverse communication interface that act on commonly used matrix data storage (dense, banded and compressed sparse row representation), using internal matrix-vector routines and selected inner linear system solvers.

For these interfaces:

- ? indicates the data type of matrix A (and matrix B if any) defined as follows:

s	float
d	double
c	MKL_Complex8
z	MKL_Complex16

- `<matrix type>` defined as follows:

Value of <i><matrix type></i>		Matrix format	Inner linear system solver used by Extended Eigensolver
sy	(symmetric real)	Dense	LAPACK dense solvers
he	(Hermitian complex)		
sb	(symmetric banded real)	Banded-LAPACK	Internal banded solver
hb	(Hermitian banded complex)		
scsr	(symmetric real)	Compressed sparse row	PARDISO solver
hcsr	(Hermitian complex)		
s	(symmetric real)	Reverse communications interfaces	User defined
h	(Hermitian complex)		

- <type of eigenvalue problem>* is:

gv	generalized eigenvalue problem
ev	standard eigenvalue problem

For example, `sfeast_scsrev` is a single-precision routine with a symmetric real matrix stored in sparse compressed-row format for a standard eigenvalue problem, and `zfeast_hrci` is a complex double-precision routine with a Hermitian matrix using the reverse communication interface.

Note that:

- ? can be `s` or `d` if a matrix is real symmetric: *<matrix type>* is `sy`, `sb`, or `scsr`.
- ? can be `c` or `z` if a matrix is complex Hermitian: *<matrix type>* is `he`, `hb`, or `hcsr`.
- ? can be `c` or `z` if the Extended Eigensolver RCI interface is used for solving a complex Hermitian problem.
- ? can be `s` or `d` if the Extended Eigensolver RCI interface is used for solving a real symmetric problem.

feastinit

Initialize Extended Eigensolver input parameters with default values.

Syntax

```
feastinit (MKL_INT* fpm);
```

Include Files

- `mkl.h`

Description

This routine sets all Extended Eigensolver parameters to their default values.

Output Parameters

fpm Array, size 128. This array is used to pass various parameters to Extended Eigensolver routines. See [Extended Eigensolver Input Parameters](#) for a complete description of the parameters and their default values.

Extended Eigensolver Input Parameters

The input parameters for Extended Eigensolver routines are contained in an `MKL_INT` array named *fpm*. To call the Extended Eigensolver interfaces, this array should be initialized using the routine [feastinit](#).

Param	Default	Description
<i>fpm</i> [0]	0	Specifies whether Extended Eigensolver routines print runtime status. <i>fpm</i>[0]=0 Extended Eigensolver routines do not generate runtime messages at all. <i>fpm</i>[0]=1 Extended Eigensolver routines print runtime status to the screen.
<i>fpm</i> [1]	8	The number of contour points $N_e = 8$ (see the description of FEAST algorithm). Must be one of {3,4,5,6,8,10,12,16,20,24,32,40,48}.
<i>fpm</i> [2]	12	Error trace double precision stopping criteria ε ($\varepsilon = 10^{-fpm[2]}$).
<i>fpm</i> [3]	20	Maximum number of Extended Eigensolver refinement loops allowed. If no convergence is reached within <i>fpm</i> [3] refinement loops, Extended Eigensolver routines return <i>info</i> =2.
<i>fpm</i> [4]	0	User initial subspace. If <i>fpm</i> [4]=0 then Extended Eigensolver routines generate initial subspace, if <i>fpm</i> [4]=1 the user supplied initial subspace is used.
<i>fpm</i> [5]	0	Extended Eigensolver stopping test. <i>fpm</i>[5]=0 - Extended Eigensolvers are stopped if this residual stopping test is satisfied: - generalized eigenvalue problem: $\max_{i=1:mode} \frac{\ Ax_i - \lambda_i Bx_i\ _1}{\max(E_{min} , E_{max}) \ Bx_i\ _1} < \varepsilon$ - standard eigenvalue problem: $\max_{i=1:mode} \frac{\ Ax_i - \lambda_i x_i\ _1}{\max(E_{min} , E_{max}) \ x_i\ _1} < \varepsilon$ - where <i>mode</i> is the total number of eigenvalues found in the search interval and $\varepsilon = 10^{-fpm[6]}$ for real and complex or $\varepsilon = 10^{-fpm[2]}$ for double precision and double complex. <i>fpm</i>[5]=1 - Extended Eigensolvers are stopped if this trace stopping test is satisfied: $\frac{ trace_j - trace_{j-1} }{\max(E_{min} , E_{max})} < \varepsilon$

Param	Default	Description
		where $trace_j$ denotes the sum of all eigenvalues found in the search interval $[emin, emax]$ at the j -th Extended Eigensolver iteration:
		$trace_j = \sum_{i=1}^M \lambda_i^{(j)}.$
$fpm[6]$	5	Error trace single precision stopping criteria ($10^{-fpm[6]}$).
$fpm[13]$	0	$fpm[13]=0$ Standard use for Extended Eigensolver routines.
		$fpm[13]=1$ Non-standard use for Extended Eigensolver routines: return the computed eigenvectors subspace after one single contour integration.
$fpm[26]$	0	Specifies whether Extended Eigensolver routines check input matrices (applies to CSR format only).
		$fpm[26]=0$ Extended Eigensolver routines do not check input matrices.
		$fpm[26]=1$ Extended Eigensolver routines check input matrices.
$fpm[27]$	0	Check if matrix B is positive definite. Set $fpm[27] = 1$ to check if B is positive definite.
$fpm[29]$ to $fpm[62]$	-	Reserved for future use.
$fpm[63]$	0	Use the Intel MKL PARDISO solver with the user-defined PARDISO $iparm$ array settings.
NOTE This option can only be used by Extended Eigensolver Predefined Interfaces for Sparse Matrices.		
		$fpm[63]=0$ Extended Eigensolver routines use the Intel MKL PARDISO default $iparm$ settings defined by calling the <code>pardisoinit</code> subroutine.
		$fpm[63]=1$ The values from $fpm[64]$ to $fpm[127]$ correspond to $iparm[0]$ to $iparm[63]$ respectively according to the formula $fpm[64 + i] = iparm[i]$ for $i = 0, 1, \dots, 63$.

Extended Eigensolver Output Details

Errors and warnings encountered during a run of the Extended Eigensolver routines are stored in an integer variable, *info*. If the value of the output *info* parameter is not 0, either an error or warning was encountered. The possible return values for the *info* parameter along with the error code descriptions are given in the following table.

Return Codes for info Parameter

<i>info</i>	Classification	Description
202	Error	Problem with size of the system n ($n \leq 0$)

<i>info</i>	Classification	Description
201	Error	Problem with size of initial subspace $m0$ ($m0 \leq 0$ or $m0 > n$)
200	Error	Problem with $emin, emax$ ($emin \geq emax$)
(100+i)	Error	Problem with i -th value of the input Extended Eigensolver parameter ($fpm[i - 1]$). Only the parameters in use are checked.
4	Warning	Successful return of only the computed subspace after call with $fpm[13] = 1$
3	Warning	Size of the subspace $m0$ is too small ($m0 < m$)
2	Warning	No Convergence (number of iteration loops $> fpm[3]$)
1	Warning	No eigenvalue found in the search interval. See remark below for further details.
0	Successful exit	
-1	Error	Internal error for allocation memory.
-2	Error	Internal error of the inner system solver. Possible reasons: not enough memory for inner linear system solver or inconsistent input.
-3	Error	Internal error of the reduced eigenvalue solver Possible cause: matrix B may not be positive definite. It can be checked by setting $fpm[27] = 1$ before calling an Extended Eigensolver routine, or by using LAPACK routines.
-4	Error	Matrix B is not positive definite.
-(100+i)	Error	Problem with the i -th argument of the Extended Eigensolver interface.

In some extreme cases the return value $info=1$ may indicate that the Extended Eigensolver routine has failed to find the eigenvalues in the search interval. This situation could arise if a very large search interval is used to locate a small and isolated cluster of eigenvalues (i.e. the dimension of the search interval is many orders of magnitude larger than the number of contour points. It is then either recommended to increase the number of contour points $fpm[1]$ or simply rescale more appropriately the search interval. Rescaling means the initial problem of finding all eigenvalues the search interval $[\lambda_{min}, \lambda_{max}]$ for the standard eigenvalue problem $Ax = \lambda x$ is replaced with the problem of finding all eigenvalues in the search interval $[\lambda_{min}/t, \lambda_{max}/t]$ for the standard eigenvalue problem $(A/t)x = (\lambda/t)x$ where t is a scaling factor.

Extended Eigensolver RCI Routines

If you do not require specific linear system solvers or matrix storage schemes, you can skip this section and go directly to [Extended Eigensolver Predefined Interfaces](#).

Extended Eigensolver RCI Interface Description

The Extended Eigensolver RCI interfaces can be used to solve standard or generalized eigenvalue problems, and are independent of the format of the matrices. As mentioned earlier, the Extended Eigensolver algorithm is based on the contour integration techniques of the matrix resolvent $G(\sigma) = (\sigma B - A)^{-1}$ over a circle. For solving a generalized eigenvalue problem, Extended Eigensolver has to perform one or more of the following operations at each contour point denoted below by Z_e :

- Factorize the matrix $(Z_e * B - A)$
- Solve the linear system $(Z_e * B - A)X = Y$ or $(Z_e * B - A)^H X = Y$ with multiple right hand sides, where H means transpose conjugate

- Matrix-matrix multiply $BX = Y$ or $AX = Y$

For solving a standard eigenvalue problem, replace the matrix B with the identity matrix I .

The primary aim of RCI interfaces is to isolate these operations: the linear system solver, factorization of the matrix resolvent at each contour point, and matrix-matrix multiplication. This gives universality to RCI interfaces as they are independent of data structures and the specific implementation of the operations like matrix-vector multiplication or inner system solvers. However, this approach requires some additional effort when calling the interface. In particular, operations listed above are performed by routines that you supply on data structures that you find most appropriate for the problem at hand.

To initialize an Extended Eigensolver RCI routine, set the job indicator (*ijob*) parameter to the value -1. When the routine requires the results of an operation, it generates a special value of *ijob* to indicate the operation that needs to be performed. The routine also returns *ze*, the coordinate along the complex contour, the values of array *work* or *workc*, and the number of columns to be used. Your subroutine then must perform the operation at the given contour point *ze*, store the results in prescribed array, and return control to the Extended Eigensolver RCI routine.

The following pseudocode shows the general scheme for using the Extended Eigensolver RCI functionality for a real symmetric problem:

```

ijob=-1; // initialization
do while (ijob!=0) {
    ?feast_src1(&ijob, &N, &Ze, work, workc, Aq, Bq,
               fpm, &epsout, &loop, &Emin, &Emax, &M0, E, lambda, &q, res, &info);

    switch(ijob) {
    case 10: // Factorize the complex matrix (ZeB-A)
        break;

    case 11: // Solve the complex linear system (ZeB-A)x=workc
        // Put result in workc
        break;

    case 30: // Perform multiplication A by Qi..Qj columns of QNxM0
        // where i = fpm[23] and j = fpm[23]+fpm[24]-1
        // Qi..Qj located in q starting from q+N*(i-1)
        break;

    case 40: // Perform multiplication B by Qi..Qj columns of QNxM0
        // where i = fpm[23] and j = fpm[23]+fpm[24]-1
        // Qi..Qj located in q starting from q+N*(i-1)
        // Result is stored in work+N*(i-1)

        break;

    }
}

```

NOTE

The ? option in ?feast in the pseudocode given above should be replaced by either *s* or *d*, depending on the matrix data type of the eigenvalue system.

The next pseudocode shows the general scheme for using the Extended Eigensolver RCI functionality for a complex Hermitian problem:

```

ijob=-1; // initialization
while (ijob!=0) {
    ?feast_hrc1(&ijob, &N, &Ze, work, workc, Aq, Bq,
               fpm, &epsout, &loop, &Emin, &Emax, &M0, E, lambda, &q, res, &info);

    switch (ijob) {
    case 10: // Factorize the complex matrix (ZeB-A)
        break;
    }
}

```

```

case 11: // Solve the linear system (ZeB-A)y=workc
        // Put result in workc
break;

case 20: // Factorize (if needed by case 21) the complex matrix      (ZeB-A)^H
        // ATTENTION: This option requires additional memory storage
        // (i.e . the resulting matrix from case 10 cannot be overwritten)
break;

case 21: // Solve the linear system (ZeB-A)^Hy=workc
        // Put result in workc
        // REMARK: case 20 becomes obsolete if this solve can be performed
        // using the factorization in case 10
break;

case 30: // Multiply A by Qi..Qj columns of QNxM0,
        // where i = fpm[23] and j = fpm[23]+fpm[24]-1
        // Qi..Qj located in q starting from q+N*(i-1)
        // Result is stored in work+N*(i-1)
break;

case 40: // Perform multiplication B by Qi..Qj columns of QNxM0
        // where i = fpm[23] and j = fpm[23]+fpm[24]-1
        // Qi..Qj located in q starting from q+N*(i-1)
        // Result is stored in work+N*(i-1)
break;

    }
}
end do

```

NOTE

The ? option in ?feast in the pseudocode given above should be replaced by either c or z, depending on the matrix data type of the eigenvalue system.

If case 20 can be avoided, performance could be up to twice as fast, and Extended Eigensolver functionality would use half of the memory.

If an iterative solver is used along with a preconditioner, the factorization of the preconditioner could be performed with *ijob* = 10 (and *ijob* = 20 if applicable) for a given value of Z_e , and the associated iterative solve would then be performed with *ijob* = 11 (and *ijob* = 21 if applicable).

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Description

Compute eigenvalues as described in [Extended Eigensolver RCI Interface Description](#).

Input Parameters

<i>ijob</i>	Job indicator variable. On entry, a call to ?feast_src/?feast_hrci with <i>ijob</i> =-1 initializes the eigensolver.
<i>n</i>	Sets the size of the problem. $n > 0$.
<i>work</i>	Workspace array of size n by $m0$.
<i>workc</i>	Workspace array of size n by $m0$.
<i>aq, sq</i>	Workspace arrays of size $m0$ by $m0$.
<i>fpm</i>	Array, size of 128. This array is used to pass various parameters to Extended Eigensolver routines. See Extended Eigensolver Input Parameters for a complete description of the parameters and their default values.
<i>emin, emax</i>	The lower and upper bounds of the interval to be searched for eigenvalues; $emin \leq emax$.
<i>m0</i>	On entry, specifies the initial guess for subspace size to be used, $0 < m0 \leq n$. Set $m0 \geq m$ where m is the total number of eigenvalues located in the interval $[emin, emax]$. If the initial guess is wrong, Extended Eigensolver routines return <i>info</i> =3.
<i>q</i>	On entry, if <i>fpm</i> [4]=1, the array <i>q</i> of size n by m contains a basis of guess subspace where n is the order of the input matrix.

Output Parameters

ijob

On exit, the parameter carries the status flag that indicates the condition of the return. The status information is divided into three categories:

1. A zero value indicates successful completion of the task.
2. A positive value indicates that the solver requires a matrix-vector multiplication or solving a specific system with a complex coefficient.
3. A negative value indicates successful initiation.

A non-zero value of *ijob* specifically means the following:

- *ijob* = 10 - factorize the complex matrix $Z_e * B - A$ at a given contour point Z_e and return the control to the ?feast_src/ ?feast_hrci routine where Z_e is a complex number meaning contour point and its value is defined internally in ?feast_src/ ?feast_hrci.
- *ijob* = 11 - solve the complex linear system $(Z_e * B - A) * y = workc$, put the solution in *workc* and return the control to the ?feast_src/ ?feast_hrci routine.
- *ijob* = 20 - factorize the complex matrix $(Z_e * B - A)^H$ at a given contour point Z_e and return the control to the ?feast_src/ ?feast_hrci routine where Z_e is a complex number meaning contour point and its value is defined internally in ?feast_src/ ?feast_hrci.

The symbol X^H means transpose conjugate of matrix X .

- *ijob* = 21 - solve the complex linear system $(Z_e * B - A)^H * y = workc$, put the solution in *workc* and return the control to the ?feast_src/ ?feast_hrci routine. The case *ijob*=20 becomes obsolete if the solve can be performed using the factorization computed for *ijob*=10.

The symbol X^H mean transpose conjugate of matrix X .

- *ijob* = 30 - multiply matrix A by $Q_j..Q_i$, put the result in *work* + $N*(i - 1)$, and return the control to the ?feast_src/ ?feast_hrci routine.
i is *fpm*[24], and *j* is *fpm*[23] + *fpm*[24] - 1.
- *ijob* = 40 - multiply matrix B by $Q_j..Q_i$, put the result in *work* + $N*(i - 1)$ and return the control to the ?feast_src/ ?feast_hrci routine. If a standard eigenvalue problem is solved, just return *work* = q.
i is *fpm*[24], and *j* is *fpm*[23] + *fpm*[24] - 1.
- *ijob* = -2 - rerun the ?feast_src/ ?feast_hrci task with the same parameters.

ze

Defines the coordinate along the complex contour. All values of *ze* are generated by ?feast_src/ ?feast_hrci internally.

fpm

On output, contains coordinates of columns of work array needed for iterative refinement. (See [Extended Eigensolver RCI Interface Description](#).)

epsout

On output, contains the relative error on the trace: $|trace_i - trace_{i-1}| / \max(|emin|, |emax|)$

loop

On output, contains the number of refinement loop executed. Ignored on input.

<i>lambda</i>	Array of length <i>m0</i> . On output, the first <i>m</i> entries of <i>lambda</i> are eigenvalues found in the interval.
<i>q</i>	On output, <i>q</i> contains all eigenvectors corresponding to <i>lambda</i> .
<i>m</i>	The total number of eigenvalues found in the interval [<i>emin</i> , <i>emax</i>]: $0 \leq m \leq m0$.
<i>res</i>	Array of length <i>m0</i>. On exit, the first <i>m</i> components contain the relative residual vector: - generalized eigenvalue problem: $\frac{\ Ax_i - \lambda_i Bx_i\ _1}{\max(E_{\min} , E_{\max}) \ Bx_i\ _1}$ - standard eigenvalue problem: $\frac{\ Ax_i - \lambda_i x_i\ _1}{\max(E_{\min} , E_{\max}) \ x_i\ _1}$ for $i=0, 1, \dots, m-1$, and where <i>m</i> is the total number of eigenvalues found in the search interval.
<i>info</i>	If <i>info</i> =0, the execution is successful. If <i>info</i> ≠ 0, see Output Eigensolver info Details .

Extended Eigensolver Predefined Interfaces

The predefined interfaces include routines for standard and generalized eigenvalue problems, and for dense, banded, and sparse matrices.

Matrix Type	Standard Eigenvalue Problem	Generalized Eigenvalue Problem
Dense	?feast_syev ?feast_heev	?feast_sygv ?feast_hgv
Banded	?feast_sbev ?feast_hbev	?feast_sbgv ?feast_hbgv
Sparse	?feast_scsrev ?feast_hcsrev	?feast_scsrgv ?feast_hcsrgv

Matrix Storage

The symmetric and Hermitian matrices used in Extended Eigensolvers predefined interfaces can be stored in full, band, and sparse formats.

- In the full storage format (described in [Full Storage](#) in additional detail) you store all elements, all of the elements in the upper triangle of the matrix, or all of the elements in the lower triangle of the matrix.
- In the band storage format (described in [Band storage](#) in additional detail), you store only the elements along a diagonal band of the matrix.

- In the sparse format (described in [Storage Arrays for a Matrix in CSR Format \(3-Array Variation\)](#)), you store only the non-zero elements of the matrix.

In generalized eigenvalue systems you must use the same family of storage format for both matrices *A* and *B*. The bandwidth can be different for the banded format (*k_{lb}* can be different from *k_{la}*), and the position of the non-zero elements can also be different for the sparse format (CSR coordinates *ib* and *jb* can be different from *ia* and *ja*).

?feast_syev/?feast_heev

Extended Eigensolver interface for standard eigenvalue problem with dense matrices.

Syntax

```
void sfeast_syev (const char * uplo, const MKL_INT * n, const float * a, const MKL_INT
* lda, MKL_INT * fpm, float * epsout, MKL_INT * loop, const float * emin, const float
* emax, MKL_INT * m0, float * e, float * x, MKL_INT * m, float * res, MKL_INT * info);

void dfeast_syev (const char * uplo, const MKL_INT * n, const double * a, const MKL_INT

Description

The routines compute all the eigenvalues and eigenvectors for standard eigenvalue problems, $Ax = \lambda x$, within a given search interval.

Input Parameters

<i>uplo</i>	Must be 'U' or 'L' or 'F' . If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular parts of <i>A</i> . If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular parts of <i>A</i> . If <i>uplo</i> = 'F', <i>a</i> stores the full matrix <i>A</i> .
<i>n</i>	Sets the size of the problem. $n > 0$.
<i>a</i>	Array of dimension <i>lda</i> by <i>n</i> , contains either full matrix <i>A</i> or upper or lower triangular part of the matrix <i>A</i> , as specified by <i>uplo</i>
<i>lda</i>	The leading dimension of the array <i>a</i> . Must be at least $\max(1, n)$.

<i>fpm</i>	Array, dimension of 128. This array is used to pass various parameters to Extended Eigensolver routines. See Extended Eigensolver Input Parameters for a complete description of the parameters and their default values.
<i>emin, emax</i>	The lower and upper bounds of the interval to be searched for eigenvalues; $emin \leq emax$.
<i>m0</i>	On entry, specifies the initial guess for subspace dimension to be used, $0 < m0 \leq n$. Set $m0 \geq m$ where m is the total number of eigenvalues located in the interval $[emin, emax]$. If the initial guess is wrong, Extended Eigensolver routines return <i>info</i> =3.
<i>x</i>	On entry, if <i>fpm</i> [4]=1, the array <i>x</i> of size n by m contains a basis of guess subspace where n is the order of the input matrix.

Output Parameters

<i>epsout</i>	On output, contains the relative error on the trace: $ trace_i - trace_{i-1} / \max(emin , emax)$
<i>loop</i>	On output, contains the number of refinement loop executed. Ignored on input.
<i>e</i>	Array of length $m0$. On output, the first m entries of <i>e</i> are eigenvalues found in the interval.
<i>x</i>	On output, the first m columns of <i>x</i> contain the orthonormal eigenvectors corresponding to the computed eigenvalues <i>e</i> , with the i -th column of <i>x</i> holding the eigenvector associated with <i>e</i> [i].
<i>m</i>	The total number of eigenvalues found in the interval $[emin, emax]$: $0 \leq m \leq m0$.
<i>res</i>	Array of length $m0$. On exit, the first m components contain the relative residual vector: $\frac{\ Ax_i - \lambda_i x_i\ _1}{\max(E_{\min} , E_{\max}) \ x_i\ _1}$ for $i=1, 2, \dots, m$, and where m is the total number of eigenvalues found in the search interval.
<i>info</i>	If <i>info</i> =0, the execution is successful. If <i>info</i> ≠0, see Output Eigensolver info Details .

?feast_sygv/?feast_hegv

Extended Eigensolver interface for generalized eigenvalue problem with dense matrices.

Syntax

```
void sfeast_sygv (const char * uplo, const MKL_INT * n, const float * a, const MKL_INT * lda, const float * b, const MKL_INT * ldb, MKL_INT * fpm, float * epsout, MKL_INT * loop, const float * emin, const float * emax, MKL_INT * m0, float * e, float * x, MKL_INT * m, float * res, MKL_INT * info);
```

```
void dfeast_sygv (const char * uplo, const MKL_INT * n, const double * a, const MKL_INT * lda, const double * b, const MKL_INT * ldb, MKL_INT * fpm, double * epsout, MKL_INT * loop, const double * emin, const double * emax, MKL_INT * m0, double * e, double * x, MKL_INT * m, double * res, MKL_INT * info);
```

```

Description

The routines compute all the eigenvalues and eigenvectors for generalized eigenvalue problems, $Ax = \lambda Bx$, within a given search interval.

Input Parameters

<i>uplo</i>	Must be 'U' or 'L' or 'F' . If <i>UPLO</i> = 'U', <i>a</i> and <i>b</i> store the upper triangular parts of <i>A</i> and <i>B</i> respectively. If <i>UPLO</i> = 'L', <i>a</i> and <i>b</i> store the lower triangular parts of <i>A</i> and <i>B</i> respectively. If <i>UPLO</i> = 'F', <i>a</i> and <i>b</i> store the full matrices <i>A</i> and <i>B</i> respectively.
<i>n</i>	Sets the size of the problem. $n > 0$.
<i>a</i>	Array of dimension <i>lda</i> by <i>n</i> , contains either full matrix <i>A</i> or upper or lower triangular part of the matrix <i>A</i> , as specified by <i>uplo</i>
<i>lda</i>	The leading dimension of the array <i>a</i> . Must be at least $\max(1, n)$.
<i>b</i>	Array of dimension <i>ldb</i> by <i>n</i> , contains either full matrix <i>B</i> or upper or lower triangular part of the matrix <i>B</i> , as specified by <i>uplo</i>
<i>ldb</i>	The leading dimension of the array <i>B</i> . Must be at least $\max(1, n)$.
<i>fpm</i>	Array, dimension of 128. This array is used to pass various parameters to Extended Eigensolver routines. See Extended Eigensolver Input Parameters for a complete description of the parameters and their default values.
<i>emin</i> , <i>emax</i>	The lower and upper bounds of the interval to be searched for eigenvalues; $emin \leq emax$.
<i>m0</i>	On entry, specifies the initial guess for subspace dimension to be used, $0 < m0 \leq n$. Set $m0 \geq m$ where <i>m</i> is the total number of eigenvalues located in the interval $[emin, emax]$. If the initial guess is wrong, Extended Eigensolver routines return <i>info</i> =3.

x On entry, if *fpm*[4]=1, the array *x* of size *n* by *m* contains a basis of guess subspace where *n* is the order of the input matrix.

Output Parameters

epsout On output, contains the relative error on the trace: $|trace_i - trace_{i-1}| / \max(|emin|, |emax|)$

loop On output, contains the number of refinement loop executed. Ignored on input.

e Array of length *m0*. On output, the first *m* entries of *e* are eigenvalues found in the interval.

x On output, the first *m* columns of *x* contain the orthonormal eigenvectors corresponding to the computed eigenvalues *e*, with the *i*-th column of *x* holding the eigenvector associated with *e*[*i*].

m The total number of eigenvalues found in the interval [*emin*, *emax*]: $0 \leq m \leq m0$.

res Array of length *m0*. On exit, the first *m* components contain the relative residual vector:

$$\frac{\|Ax_i - \lambda_i Bx_i\|_1}{\max(|E_{\min}|, |E_{\max}|) \|Bx_i\|_1}$$

for *i*=1, 2, ..., *m*, and where *m* is the total number of eigenvalues found in the search interval.

info If *info*=0, the execution is successful. If *info*≠ 0, see [Output Eigensolver info Details](#).

?feast_sbev/?feast_hbev

Extended Eigensolver interface for standard eigenvalue problem with banded matrices.

Syntax

```

Description

The routines compute all the eigenvalues and eigenvectors for generalized eigenvalue problems, $Ax = \lambda Bx$, within a given search interval.

NOTE

Both matrices A and B must use the same family of storage format. The bandwidth, however, can be different (k_{lb} can be different from k_{la}).

Input Parameters

<i>uplo</i>	Must be 'U' or 'L' or 'F' . If $UPLO = 'U'$, a and b store the upper triangular parts of A and B respectively. If $UPLO = 'L'$, a and b store the lower triangular parts of A and B respectively. If $UPLO = 'F'$, a and b store the full matrices A and B respectively.
<i>n</i>	Sets the size of the problem. $n > 0$.
<i>kla</i>	The number of super- or sub-diagonals within the band in A ($k_{la} \geq 0$).
<i>a</i>	Array of dimension lda by n , contains either full matrix A or upper or lower triangular part of the matrix A , as specified by <i>uplo</i>
<i>lda</i>	The leading dimension of the array a . Must be at least $\max(1, n)$.
<i>k1b</i>	The number of super- or sub-diagonals within the band in B ($k_{1b} \geq 0$).
<i>b</i>	Array of dimension ldb by n , contains either full matrix B or upper or lower triangular part of the matrix B , as specified by <i>uplo</i>
<i>ldb</i>	The leading dimension of the array B . Must be at least $\max(1, n)$.
<i>fpm</i>	Array, dimension of 128. This array is used to pass various parameters to Extended Eigensolver routines. See Extended Eigensolver Input Parameters for a complete description of the parameters and their default values.
<i>emin, emax</i>	The lower and upper bounds of the interval to be searched for eigenvalues; $emin \leq emax$.
<i>m0</i>	On entry, specifies the initial guess for subspace dimension to be used, $0 < m0 \leq n$. Set $m0 \geq m$ where m is the total number of eigenvalues located in the interval $[emin, emax]$. If the initial guess is wrong, Extended Eigensolver routines return <i>info</i> =3.
<i>x</i>	On entry, if $fpm[4] = 1$, the array x of size n by m contains a basis of guess subspace where n is the order of the input matrix.

Output Parameters

<i>epsout</i>	On output, contains the relative error on the trace: $ trace_i - trace_{i-1} / \max(emin , emax)$
<i>loop</i>	On output, contains the number of refinement loop executed. Ignored on input.

e	Array of length $m0$. On output, the first m entries of e are eigenvalues found in the interval.
x	On output, the first m columns of x contain the orthonormal eigenvectors corresponding to the computed eigenvalues e , with the i -th column of x holding the eigenvector associated with $e[i]$.
m	The total number of eigenvalues found in the interval $[e_{min}, e_{max}]$: $0 \leq m \leq m0$.
res	Array of length $m0$. On exit, the first m components contain the relative residual vector: $\frac{\ Ax_i - \lambda_i Bx_i\ _1}{\max(E_{min} , E_{max}) \ Bx_i\ _1}$ for $i=1, 2, \dots, m$, and where m is the total number of eigenvalues found in the search interval.
$info$	If $info=0$, the execution is successful. If $info \neq 0$, see Output Eigensolver info Details .

?feast_scsrev/?feast_hcsrev

Extended Eigensolver interface for standard eigenvalue problem with sparse matrices.

Syntax

```
void sfeast_scsrev (const char * uplo, const MKL_INT * n, const float * a, const
MKL_INT * ia, const MKL_INT * ja, MKL_INT * fpm, float * epsout, MKL_INT * loop, const

The routines compute all the eigenvalues and eigenvectors for standard eigenvalue problems, $Ax = \lambda x$, within a given search interval.

Input Parameters

<i>uplo</i>	Must be 'U' or 'L' or 'F' . If <i>uplo</i> = 'U', <i>a</i> stores the upper triangular parts of <i>A</i> . If <i>uplo</i> = 'L', <i>a</i> stores the lower triangular parts of <i>A</i> . If <i>uplo</i> = 'F' , <i>a</i> stores the full matrix <i>A</i> .
<i>n</i>	Sets the size of the problem. $n > 0$.
<i>a</i>	Array containing the nonzero elements of either the full matrix <i>A</i> or the upper or lower triangular part of the matrix <i>A</i> , as specified by <i>uplo</i> .
<i>ia</i>	Array of length $n + 1$, containing indices of elements in the array <i>a</i> , such that <i>ia</i> [<i>i</i>] is the index in the array <i>a</i> of the first non-zero element from the row <i>i</i> . The value of the last element <i>ia</i> [<i>n</i>] is equal to the number of non-zeros plus one.
<i>ja</i>	Array containing the column indices for each non-zero element of the matrix <i>A</i> being represented in the array <i>a</i> . Its length is equal to the length of the array <i>a</i> .
<i>fpm</i>	Array, dimension of 128. This array is used to pass various parameters to Extended Eigensolver routines. See Extended Eigensolver Input Parameters for a complete description of the parameters and their default values.
<i>emin, emax</i>	The lower and upper bounds of the interval to be searched for eigenvalues; $emin \leq emax$.
<i>m0</i>	On entry, specifies the initial guess for subspace dimension to be used, $0 < m0 \leq n$. Set $m0 \geq m$ where <i>m</i> is the total number of eigenvalues located in the interval [<i>emin</i> , <i>emax</i>]. If the initial guess is wrong, Extended Eigensolver routines return <i>info</i> =3.
<i>x</i>	On entry, if <i>fpm</i> [4]=1, the array <i>x</i> of size <i>n</i> by <i>m</i> contains a basis of guess subspace where <i>n</i> is the order of the input matrix.

Output Parameters

<i>fpm</i>	On output, the last 64 values correspond to Intel MKL PARDISO <i>iparm</i> [0] to <i>iparm</i> [63] (regardless of the value of <i>fpm</i> [63] on input).
<i>epsout</i>	On output, contains the relative error on the trace: $ trace_i - trace_{i-1} / \max(emin , emax)$
<i>loop</i>	On output, contains the number of refinement loop executed. Ignored on input.
<i>e</i>	Array of length <i>m0</i> . On output, the first <i>m</i> entries of <i>e</i> are eigenvalues found in the interval.
<i>x</i>	On output, the first <i>m</i> columns of <i>x</i> contain the orthonormal eigenvectors corresponding to the computed eigenvalues <i>e</i> , with the <i>i</i> -th column of <i>x</i> holding the eigenvector associated with <i>e</i> [<i>i</i>].

<i>m</i>	The total number of eigenvalues found in the interval $[e_{min}, e_{max}]$: $0 \leq m \leq m0$.
<i>res</i>	Array of length <i>m0</i>. On exit, the first <i>m</i> components contain the relative residual vector: $\frac{\ Ax_i - \lambda_i x_i\ _1}{\max(E_{min} , E_{max}) \ x_i\ _1}$ for $i=1, 2, \dots, m$, and where <i>m</i> is the total number of eigenvalues found in the search interval.
<i>info</i>	If <i>info</i> =0, the execution is successful. If <i>info</i> ≠ 0, see Output Eigensolver info Details .

?feast_scsrgv/?feast_hcsrgv

Extended Eigensolver interface for generalized eigenvalue problem with sparse matrices.

Syntax

```

- mkl.h

Description

The routines compute all the eigenvalues and eigenvectors for generalized eigenvalue problems, $Ax = \lambda Bx$, within a given search interval.

NOTE

Both matrices A and B must use the same family of storage format. The position of the non-zero elements can be different (CSR coordinates ib and jb can be different from ia and ja).

Input Parameters

<i>uplo</i>	Must be 'U' or 'L' or 'F' . If $UPLO = 'U'$, a and b store the upper triangular parts of A and B respectively. If $UPLO = 'L'$, a and b store the lower triangular parts of A and B respectively. If $UPLO = 'F'$, a and b store the full matrices A and B respectively.
<i>n</i>	Sets the size of the problem. $n > 0$.
<i>a</i>	Array containing the nonzero elements of either the full matrix A or the upper or lower triangular part of the matrix A , as specified by <i>uplo</i> .
<i>ia</i>	Array of length $n + 1$, containing indices of elements in the array a , such that $ia[i - 1]$ is the index in the array a of the first non-zero element from the row i . The value of the last element $ia[n]$ is equal to the number of non-zeros plus one.
<i>ja</i>	Array containing the column indices for each non-zero element of the matrix A being represented in the array a . Its length is equal to the length of the array a .
<i>b</i>	Array of dimension ldb by *, contains either full matrix B or upper or lower triangular part of the matrix B , as specified by <i>uplo</i>
<i>ib</i>	Array of length $n + 1$, containing indices of elements in the array b , such that $ib[i - 1]$ is the index in the array b of the first non-zero element from the row i . The value of the last element $ib[n]$ is equal to the number of non-zeros plus one.
<i>jb</i>	Array containing the column indices for each non-zero element of the matrix B being represented in the array b . Its length is equal to the length of the array b .
<i>fpm</i>	Array, dimension of 128. This array is used to pass various parameters to Extended Eigensolver routines. See Extended Eigensolver Input Parameters for a complete description of the parameters and their default values.
<i>emin, emax</i>	The lower and upper bounds of the interval to be searched for eigenvalues; $emin \leq emax$.
<i>m0</i>	On entry, specifies the initial guess for subspace dimension to be used, $0 < m0 \leq n$. Set $m0 \geq m$ where m is the total number of eigenvalues located in the interval $[emin, emax]$. If the initial guess is wrong, Extended Eigensolver routines return <i>info</i> =3.

x On entry, if $fpm[4]=1$, the array x of size n by m contains a basis of guess subspace where n is the order of the input matrix.

Output Parameters

fpm On output, the last 64 values correspond to Intel MKL PARDISO $iparm[0]$ to $iparm[63]$ (regardless of the value of $fpm[63]$ on input).

$epsout$ On output, contains the relative error on the trace: $|trace_i - trace_{i-1}| / \max(|emin|, |emax|)$

$loop$ On output, contains the number of refinement loop executed. Ignored on input.

e Array of length $m0$. On output, the first m entries of e are eigenvalues found in the interval.

x On output, the first m columns of x contain the orthonormal eigenvectors corresponding to the computed eigenvalues e , with the i -th column of x holding the eigenvector associated with $e[i]$.

m The total number of eigenvalues found in the interval $[emin, emax]$: $0 \leq m \leq m0$.

res Array of length $m0$. On exit, the first m components contain the relative residual vector:

$$\frac{\|Ax_i - \lambda_i Bx_i\|_1}{\max(|E_{\min}|, |E_{\max}|) \|Bx_i\|_1}$$

for $i=1, 2, \dots, m$, and where m is the total number of eigenvalues found in the search interval.

$info$ If $info=0$, the execution is successful. If $info \neq 0$, see [Output Eigensolver info Details](#).

Vector Mathematical Functions

This chapter describes Intel® MKL Vector Mathematics functions (VM), which compute a mathematical function of each of the vector elements. VM includes a set of highly optimized functions (arithmetic, power, trigonometric, exponential, hyperbolic, special, and rounding) that operate on vectors of real and complex numbers.

Application programs that improve performance with VM include nonlinear programming software, computation of integrals, financial calculations, computer graphics, and many others.

VM functions fall into the following groups according to the operations they perform:

- **VM Mathematical Functions** compute values of mathematical functions, such as sine, cosine, exponential, or logarithm, on vectors stored contiguously in memory.
- **VM Pack/Unpack Functions** convert to and from vectors with positive increment indexing, vector indexing, and mask indexing (see [Appendix B](#) for details on vector indexing methods).
- **VM Service Functions** set/get the accuracy modes and the error codes, and free memory.

The VM mathematical functions take an input vector as an argument, compute values of the respective function element-wise, and return the results in an output vector. All the VM mathematical functions can perform in-place operations, where the input and output arrays are at the same memory locations.

The Intel MKL interfaces are given in `mkl_vml_functions.h`.

Examples that demonstrate how to use the VM functions are located in:

`${MKL}/examples/vmlc/source`

See VM performance and accuracy data in the online VM Performance and Accuracy Data document available at <http://software.intel.com/en-us/articles/intel-math-kernel-library-documentation/>

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Data Types, Accuracy Modes, and Performance Tips

VM includes mathematical and pack/unpack vector functions for single and double precision vector arguments of real and complex types. Intel MKL provides Fortran and C interfaces for all VM functions, including the associated service functions. The Function Naming Conventions section below shows how to call these functions.

Performance depends on a number of factors, including vectorization and threading overhead. The recommended usage is as follows:

- Use VM for vector lengths larger than 40 elements.
- Use the Intel® Compiler for vector lengths less than 40 elements.

All VM vector functions support the following accuracy modes:

- High Accuracy (HA), the default mode
- Low Accuracy (LA), which improves performance by reducing accuracy of the two least significant bits
- Enhanced Performance (EP), which provides better performance at the cost of significantly reduced accuracy. Approximately half of the bits in the mantissa are correct.

Note that using the EP mode does not guarantee accurate processing of corner cases and special values. Although the default accuracy is HA, LA is sufficient in most cases. For applications that require less accuracy (for example, media applications, some Monte Carlo simulations, etc.), the EP mode may be sufficient.

VM handles special values in accordance with the C99 standard [C99].

Intel MKL offers both functions and environment variables to switch between modes for VM. See the *Intel MKL User's Guide* for details about the environment variables. Use the `vm1SetMode(mode)` function (see [Table "Values of the mode Parameter"](#)) to switch between the HA, LA, and EP modes. The `vm1GetMode()` function returns the current mode.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

[Function Naming Conventions](#)

Function Naming Conventions

The VM function names are of mixed (lower and upper) case.

The VM mathematical and pack/unpack function names have the following structure:

`v[m]<?><name><mod>`

where

- `v` is a prefix indicating vector operations.
- `[m]` is an optional prefix for mathematical functions that indicates additional argument to specify a VM mode for a given function call (see [vm1SetMode](#) for possible values and their description).
- `<?>` is a precision prefix that indicates one of the following the data types:

<code>s</code>	<code>float.</code>
<code>d</code>	<code>double.</code>
<code>c</code>	<code>MKL_Complex8.</code>
<code>z</code>	<code>MKL_Complex16.</code>

- `<name>` indicates the function short name, with some of its letters in uppercase. See examples in [Table "VM Mathematical Functions"](#).
- `<mod>` field (written in uppercase) is present only in the pack/unpack functions and indicates the indexing method used:

<code>i</code>	indexing with a positive increment
<code>v</code>	indexing with an index vector

m indexing with a mask vector.

The VM service function names have the following structure:

vm<name>

where

<name> indicates the function short name, with some of its letters in uppercase. See examples in [Table "VM Service Functions"](#).

To call VM functions from an application program, use conventional function calls. For example, call the vector single precision real exponential function as

```
vsExp ( n, a, y );
```

Function Interfaces

VM interfaces include the function names and argument lists. The following sections describe the interfaces for the VM functions. Note that some of the functions have multiple input and output arguments

Some VM functions may also take scalar arguments as input. See the function description for the naming conventions of such arguments.

VM Mathematical Functions

```
v<?><name>( n, a, [scalar input arguments],y );
v<?><name>( n, a, b, [scalar input arguments],y );
v<?><name>( n, a, y, z );
vm<?><name>( n, a, [scalar input arguments],y, mode );
vm<?><name>( n, a, b, [scalar input arguments],y, mode );
vm<?><name>( n, a, y, z, mode );
```

Pack Functions

```
v<?>PackI( n, a, inca, y );
v<?>PackV( n, a, ia, y );
v<?>PackM( n, a, ma, y );
```

Unpack Functions

```
v<?>UnpackI( n, a, y, incy );
v<?>UnpackV( n, a, y, iy );
v<?>UnpackM( n, a, y, my );
```

Service Functions

```
oldmode = vmlSetMode( mode );
mode = vmlGetMode( void );
olderr = vmlSetErrStatus ( err );
err = vmlGetErrStatus( void );
olderr = vmlClearErrStatus( void );
oldcallback = vmlSetErrorCallBack( callback );
callback = vmlGetErrorCallBack( void );
oldcallback = vmlClearErrorCallBack( void );
```

Note that *oldmode*, *olderr*, and *oldcallback* refer to settings prior to the call.

Input Parameters

<i>n</i>	number of elements to be calculated
<i>a</i>	first input vector
<i>b</i>	second input vector
<i>inca</i>	vector increment for the input vector <i>a</i>
<i>ia</i>	index vector for the input vector <i>a</i>
<i>ma</i>	mask vector for the input vector <i>a</i>
<i>incy</i>	vector increment for the output vector <i>y</i>
<i>iy</i>	index vector for the output vector <i>y</i>
<i>my</i>	mask vector for the output vector <i>y</i>
<i>err</i>	error code
<i>mode</i>	VM mode
<i>callback</i>	address of the callback function

Output Parameters

<i>y</i>	first output vector
<i>z</i>	second output vector
<i>err</i>	error code
<i>mode</i>	VM mode
<i>olderr</i>	former error code
<i>oldmode</i>	former VM mode
<i>callback</i>	address of the callback function
<i>oldcallback</i>	address of the former callback function

See the data types of the parameters used in each function in the respective function description section. All the Intel MKL VM mathematical functions can perform in-place operations.

Vector Indexing Methods

VM mathematical functions work only with unit stride. To accommodate arrays with other increments, or more complicated indexing, you can gather the elements into a contiguous vector and then scatter them after the computation is complete.

VM uses the three following indexing methods to do this task:

- positive increment
- index vector
- mask vector

The indexing method used in a particular function is indicated by the indexing modifier (see the description of the `<mod>` field in [Function Naming Conventions](#)). For more information on the indexing methods, see [Vector Arguments in VM](#) in Appendix B.

Error Diagnostics

The VM mathematical functions incorporate the error handling mechanism, which is controlled by the following service functions:

<code>vmlGetErrStatus,</code> <code>vmlSetErrStatus,</code> <code>vmlClearErrStatus</code>	These functions operate with a global variable called VM Error Status. The VM Error Status flags an error, a warning, or a successful execution of a VM function.
<code>vmlGetErrCallBack,</code> <code>vmlSetErrCallBack,</code> <code>vmlClearErrCallBack</code>	These functions enable you to customize the error handling. For example, you can identify a particular argument in a vector where an error occurred or that caused a warning.
<code>vmlSetMode, vmlGetMode</code>	These functions get and set a VM mode. If you set a new VM mode using the <code>vmlSetMode</code> function, you can store the previous VM mode returned by the routine and restore it at any point of your application.

If both an error and a warning situation occur during the function call, the VM Error Status variable keeps only the value of the error code. See [Table "Values of the VM Error Status"](#) for possible values. If a VM function does not encounter errors or warnings, it sets the VM Error Status to `VML_STATUS_OK`.

If you use incorrect input arguments to a VM function (`VML_STATUS_BADSIZE` and `VML_STATUS_BADMEM`), the function calls `xerbla` to report errors. See [Table "Values of the VM Error Status"](#) for details

You can use the `vmlSetMode` and `vmlGetMode` functions to modify error handling behavior. Depending on the VM mode, the error handling behavior includes the following operations:

- setting the VM Error Status to a value corresponding to the observed error or warning
- setting the `errno` variable to one of the values described in [Table "Set Values of the `errno` Variable"](#)
- writing error text information to the `stderr` stream
- raising the appropriate exception on an error, if necessary
- calling the additional error handler callback function that is set by `vmlSetErrorCallBack`.

Set Values of the `errno` Variable

Value of <code>errno</code>	Description
<code>0</code>	No errors are detected.
<code>EINVAL</code>	The array dimension is not positive.
<code>EACCES</code>	NULL pointer is passed.
<code>EDOM</code>	At least one of array values is out of a range of definition.
<code>ERANGE</code>	At least one of array values caused a singularity, overflow or underflow.

See Also

[vmlGetErrStatus](#) Gets the VM Error Status.

[vmlSetErrStatus](#) Sets the new VM Error Status according to `err` and stores the previous VM Error Status to `olderr`.

[vmlClearErrStatus](#) Sets the VM Error Status to `VML_STATUS_OK` and stores the previous VM Error Status to `olderr`.

[vmlSetErrorCallBack](#) Sets the additional error handler callback function and gets the old callback function.

[vmlGetErrorCallBack](#) Gets the additional error handler callback function.

vmiClearErrorCallback Deletes the additional error handler callback function and retrieves the former callback function.

vmiGetMode Gets the VM mode.

vmiSetMode Sets a new mode for VM functions according to the *mode* parameter and stores the previous VM mode to *oldmode*.

VM Mathematical Functions

This section describes VM functions that compute values of mathematical functions on real and complex vector arguments with unit increment.

Each function is introduced by its short name, a brief description of its purpose, and the calling sequence for each type of data, as well as a description of the input/output arguments.

The input range of parameters is equal to the mathematical range of the input data type, unless the function description specifies input threshold values, which mark off the precision overflow, as follows:

- *FLT_MAX* denotes the maximum number representable in single precision real data type
- *DBL_MAX* denotes the maximum number representable in double precision real data type

Table "VM Mathematical Functions" lists available mathematical functions and associated data types.

VM Mathematical Functions

Function	Data Types	Description
Arithmetic Functions		
v?Add	<i>s, d, c, z</i>	Addition of vector elements
v?Sub	<i>s, d, c, z</i>	Subtraction of vector elements
v?Sqr	<i>s, d</i>	Squaring of vector elements
v?Mul	<i>s, d, c, z</i>	Multiplication of vector elements
v?MulByConj	<i>c, z</i>	Multiplication of elements of one vector by conjugated elements of the second vector
v?Conj	<i>c, z</i>	Conjugation of vector elements
v?Abs	<i>s, d, c, z</i>	Computation of the absolute value of vector elements
v?Arg	<i>c, z</i>	Computation of the argument of vector elements
v?LinearFrac	<i>s, d</i>	Linear fraction transformation of vectors
Power and Root Functions		
v?Inv	<i>s, d</i>	Inversion of vector elements
v?Div	<i>s, d, c, z</i>	Division of elements of one vector by elements of the second vector
v?Sqrt	<i>s, d, c, z</i>	Computation of the square root of vector elements
v?InvSqrt	<i>s, d</i>	Computation of the inverse square root of vector elements
v?Cbirt	<i>s, d</i>	Computation of the cube root of vector elements
v?InvCbirt	<i>s, d</i>	Computation of the inverse cube root of vector elements
v?Pow2o3	<i>s, d</i>	Raising each vector element to the power of 2/3
v?Pow3o2	<i>s, d</i>	Raising each vector element to the power of 3/2
v?Pow	<i>s, d, c, z</i>	Raising each vector element to the specified power
v?Powx	<i>s, d, c, z</i>	Raising each vector element to the constant power
v?Hypot	<i>s, d</i>	Computation of the square root of sum of squares
Exponential and Logarithmic Functions		
v?Exp	<i>s, d, c, z</i>	Computation of the exponential of vector elements
v?Expml	<i>s, d</i>	Computation of the exponential of vector elements decreased by 1
v?Ln	<i>s, d, c, z</i>	Computation of the natural logarithm of vector elements
v?Log10	<i>s, d, c, z</i>	Computation of the denary logarithm of vector elements
v?Loglp	<i>s, d</i>	Computation of the natural logarithm of vector elements that are increased by 1
Trigonometric Functions		
v?Cos	<i>s, d, c, z</i>	Computation of the cosine of vector elements

Function	Data Types	Description
<code>v?Sin</code>	s, d, c, z	Computation of the sine of vector elements
<code>v?SinCos</code>	s, d	Computation of the sine and cosine of vector elements
<code>v?CIS</code>	c, z	Computation of the complex exponent of vector elements (cosine and sine combined to complex value)
<code>v?Tan</code>	s, d, c, z	Computation of the tangent of vector elements
<code>v?Acos</code>	s, d, c, z	Computation of the inverse cosine of vector elements
<code>v?Asin</code>	s, d, c, z	Computation of the inverse sine of vector elements
<code>v?Atan</code>	s, d, c, z	Computation of the inverse tangent of vector elements
<code>v?Atan2</code>	s, d	Computation of the four-quadrant inverse tangent of elements of two vectors
Hyperbolic Functions		
<code>v?Cosh</code>	s, d, c, z	Computation of the hyperbolic cosine of vector elements
<code>v?Sinh</code>	s, d, c, z	Computation of the hyperbolic sine of vector elements
<code>v?Tanh</code>	s, d, c, z	Computation of the hyperbolic tangent of vector elements
<code>v?Acosh</code>	s, d, c, z	Computation of the inverse hyperbolic cosine of vector elements
<code>v?Asinh</code>	s, d, c, z	Computation of the inverse hyperbolic sine of vector elements
<code>v?Atanh</code>	s, d, c, z	Computation of the inverse hyperbolic tangent of vector elements.
Special Functions		
<code>v?Erf</code>	s, d	Computation of the error function value of vector elements
<code>v?Erfc</code>	s, d	Computation of the complementary error function value of vector elements
<code>v?CdfNorm</code>	s, d	Computation of the cumulative normal distribution function value of vector elements
<code>v?ErfInv</code>	s, d	Computation of the inverse error function value of vector elements
<code>v?ErfcInv</code>	s, d	Computation of the inverse complementary error function value of vector elements
<code>v?CdfNormInv</code>	s, d	Computation of the inverse cumulative normal distribution function value of vector elements
<code>v?LGamma</code>	s, d	Computation of the natural logarithm for the absolute value of the gamma function of vector elements
<code>v?TGamma</code>	s, d	Computation of the gamma function of vector elements
Rounding Functions		
<code>v?Floor</code>	s, d	Rounding towards minus infinity
<code>v?Ceil</code>	s, d	Rounding towards plus infinity
<code>v?Trunc</code>	s, d	Rounding towards zero infinity
<code>v?Round</code>	s, d	Rounding to nearest integer
<code>v?NearbyInt</code>	s, d	Rounding according to current mode
<code>v?Rint</code>	s, d	Rounding according to current mode and raising inexact result exception
<code>v?Modf</code>	s, d	Computation of the integer and fractional parts
<code>v?Frac</code>	s, d	Computation of the fractional part

Special Value Notations

This section defines notations of special values for complex functions. The definitions are provided in text, tables, or formulas.

- $z, z1, z2$, etc. denote complex numbers.
- $i, i^2=-1$ is the imaginary unit.
- $x, X, x1, x2$, etc. denote real imaginary parts.
- $y, Y, y1, y2$, etc. denote imaginary parts.
- X and Y represent any finite positive IEEE-754 floating point values, if not stated otherwise.
- Quiet NaN and signaling NaN are denoted with `QNaN` and `SNAN`, respectively.
- The IEEE-754 positive infinities or floating-point numbers are denoted with a + sign before x, y , etc.

- The IEEE-754 negative infinities or floating-point numbers are denoted with a – sign before x , y , etc.

$\text{CONJ}(z)$ and $\text{CIS}(z)$ are defined as follows:

$\text{CONJ}(x+i \cdot y)=x-i \cdot y$

$\text{CIS}(y)=\cos (y)+i \cdot \sin (y)$.

The special value tables show the result of the function for the z argument at the intersection of the $\text{RE}(z)$ column and the $i \cdot \text{IM}(z)$ row. If the function raises an exception on the argument z , the lower part of this cell shows the raised exception and the VM Error Status. An empty cell indicates that this argument is normal and the result is defined mathematically.

Arithmetic Functions

Arithmetic functions perform the basic mathematical operations like addition, subtraction, multiplication or computation of the absolute value of the vector elements.

v?Add

Performs element by element addition of vector a and vector b .

Syntax

```
vsAdd( n, a, b, y );
vmsAdd( n, a, b, y, mode );
vdAdd( n, a, b, y );
vmdAdd( n, a, b, y, mode );
vcAdd( n, a, b, y );
vmcAdd( n, a, b, y, mode );
vzAdd( n, a, b, y );
vmzAdd( n, a, b, y, mode );
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
n	const MKL_INT	Specifies the number of elements to be calculated.
a, b	const float* for vsAdd, vmsAdd const double* for vdAdd, vmdAdd const MKL_Complex8* for vcAdd, vmcAdd const MKL_Complex16* for vzAdd, vmzAdd	Pointers to arrays that contain the input vectors a and b .

Name	Type	Description
<i>mode</i>	const MKL_INT64	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
<i>y</i>	float* for vsAdd, vmsAdd double* for vdAdd, vmdAdd MKL_Complex8* for vcAdd, vmcAdd MKL_Complex16* for vzAdd, vmzAdd	Pointer to an array that contains the output vector <i>y</i> .

Description

The *v?Add* function performs element by element addition of vector *a* and vector *b*.

Special values for Real Function *v?Add(x)*

Argument 1	Argument 2	Result	Exception
+0	+0	+0	
+0	-0	+0	
-0	+0	+0

SNAN	any value	QNAN	INVALID
any value	SNAN	QNAN	INVALID
QNAN	non-SNAN	QNAN	
non-SNAN	QNAN	QNAN	

Specifications for special values of the complex functions are defined according to the following formula

$$\text{Add}(x1+i*y1, x2+i*y2) = (x1+x2) + i*(y1+y2)$$

Overflow in a complex function occurs (supported in the HA/LA accuracy modes only) when *x1*, *x2*, *y1*, *y2* are finite numbers, but the real or imaginary part of the computed result is so large that it does not fit the target precision. In this case, the function returns ∞ in that part of the result, raises the `OVERFLOW` exception, and sets the VM Error Status to `VML_STATUS_OVERFLOW` (overriding any possible `VML_STATUS_ACCURACYWARNING` status).

v?Sub

*Performs element by element subtraction of vector *b* from vector *a*.*

Syntax

```
vsSub( n, a, b, y );
```

```
vmsSub( n, a, b, y, mode );
```

```
vdSub( n, a, b, y );
```

```
vmdSub( n, a, b, y, mode );
```

```
vcSub( n, a, b, y );
vmcSub( n, a, b, y, mode );
vzSub( n, a, b, y );
vmzSub( n, a, b, y, mode );
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>n</i>	const MKL_INT	Specifies the number of elements to be calculated.
<i>a, b</i>	const float* for vsSub, vmsSub const double* for vdSub, vmdSub const MKL_Complex8* for vcSub, vmcSub const MKL_Complex16* for vzSub, vmzSub	Pointers to arrays that contain the input vectors <i>a</i> and <i>b</i> .
<i>mode</i>	const MKL_INT64	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
<i>y</i>	float* for vsSub, vmsSub double* for vdSub, vmdSub MKL_Complex8* for vcSub, vmcSub MKL_Complex16* for vzSub, vmzSub	Pointer to an array that contains the output vector <i>y</i> .

Description

The `v?Sub` function performs element by element subtraction of vector *b* from vector *a*.

Specifications for special values of the complex functions are defined according to the following formula

$$\text{Mul}(x1+i*y1, x2+i*y2) = (x1*x2-y1*y2) + i*(x1*y2+y1*x2).$$

Overflow in a complex function occurs (supported in the HA/LA accuracy modes only) when *x1*, *x2*, *y1*, *y2* are finite numbers, but the real or imaginary part of the computed result is so large that it does not fit the target precision. In this case, the function returns ∞ in that part of the result, raises the `OVERFLOW` exception, and sets the VM Error Status to `VML_STATUS_OVERFLOW` (overriding any possible `VML_STATUS_ACCURACYWARNING` status).

v?MulByConj

*Performs element by element multiplication of vector *a* element and conjugated vector *b* element.*

Syntax

```
vcMulByConj( n, a, b, y );
```

```
vmcMulByConj( n, a, b, y, mode );
vzMulByConj( n, a, b, y );
vmzMulByConj( n, a, b, y, mode );
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>n</i>	const MKL_INT	Specifies the number of elements to be calculated.
<i>a, b</i>	const MKL_Complex8* for vcMulByConj, vmcMulByConj const MKL_Complex16* for vzMulByConj, vmzMulByConj	Pointers to arrays that contain the input vectors <i>a</i> and <i>b</i> .
<i>mode</i>	const MKL_INT64	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
<i>y</i>	MKL_Complex8* for vcMulByConj, vmcMulByConj MKL_Complex16* for vzMulByConj, vmzMulByConj	Pointer to an array that contains the output vector <i>y</i> .

Description

The `v?MulByConj` function performs element by element multiplication of vector *a* element and conjugated vector *b* element.

Specifications for special values of the functions are found according to the formula

$$\text{MulByConj}(x1+i*y1, x2+i*y2) = \text{Mul}(x1+i*y1, x2-i*y2).$$

Overflow in a complex function occurs (supported in the HA/LA accuracy modes only) when *x1*, *x2*, *y1*, *y2* are finite numbers, but the real or imaginary part of the computed result is so large that it does not fit the target precision. In this case, the function returns ∞ in that part of the result, raises the `OVERFLOW` exception, and sets the VM Error Status to `VML_STATUS_OVERFLOW` (overriding any possible `VML_STATUS_ACCURACYWARNING` status).

v?Conj

Performs element by element conjugation of the vector.

Syntax

```
vcConj( n, a, y );
vmcConj( n, a, y, mode );
vzConj( n, a, y );
```

```
vmzConj( n, a, y, mode );
```

Include Files

- `mk1.h`

Input Parameters

Name	Type	Description
<i>n</i>	<code>const MKL_INT</code>	Specifies the number of elements to be calculated.
<i>a</i>	<code>const MKL_Complex8*</code> for <code>vcConj</code> , <code>vmcConj</code> <code>const MKL_Complex16*</code> for <code>vzConj</code> , <code>vmzConj</code>	Pointer to an array that contains the input vector <i>a</i> .
<i>mode</i>	<code>const MKL_INT64</code>	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
<i>y</i>	<code>MKL_Complex8*</code> for <code>vcConj</code> , <code>vmcConj</code> <code>MKL_Complex16*</code> for <code>vzConj</code> , <code>vmzConj</code>	Pointer to an array that contains the output vector <i>y</i> .

Description

The `v?Conj` function performs element by element conjugation of the vector.

No special values are specified. The function does not raise floating-point exceptions.

v?Abs

Computes absolute value of vector elements.

Syntax

```
vsAbs( n, a, y );
```

```
vmsAbs( n, a, y, mode );
```

```
vdAbs( n, a, y );
```

```
vmdAbs( n, a, y, mode );
```

```
vcAbs( n, a, y );
```

```
vmcAbs( n, a, y, mode );
```

```
vzAbs( n, a, y );
```

```
vmzAbs( n, a, y, mode );
```

Include Files

- `mk1.h`

Input Parameters

Name	Type	Description
<i>n</i>	const MKL_INT	Specifies the number of elements to be calculated.
<i>a</i>	const float* for vsAbs, vmsAbs const double* for vdAbs, vmdAbs const MKL_Complex8* for vcAbs, vmcAbs const MKL_Complex16* for vzAbs, vmzAbs	Pointer to an array that contains the input vector <i>a</i> .
<i>mode</i>	const MKL_INT64	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
<i>y</i>	float* for vsAbs, vmsAbs, vcAbs, vmcAbs double* for vdAbs, vmdAbs, vzAbs, vmzAbs	Pointer to an array that contains the output vector <i>y</i> .

Description

The *v?Abs* function computes an absolute value of vector elements.

Special Values for Real Function *v?Abs(x)*

Argument	Result	Exception
+0	+0	
-0	+0	
$+\infty$	$+\infty$	
$-\infty$	$+\infty$	
QNaN	QNaN	
SNAN	QNaN	INVALID

Specifications for special values of the complex functions are defined according to the following formula

$$\text{Abs}(z) = \text{Hypot}(\text{RE}(z), \text{IM}(z)).$$

v?Arg

Computes argument of vector elements.

Syntax

```
vcArg( n, a, y );
```

```
vmcArg( n, a, y, mode );
```

```
vzArg( n, a, y );
```

```
vmzArg( n, a, y, mode );
```

Include Files

- `mk1.h`

Input Parameters

Name	Type	Description
n	<code>const MKL_INT</code>	Specifies the number of elements to be calculated.
a	<code>const MKL_Complex8*</code> for <code>vcArg</code> , <code>vmcArg</code> <code>const MKL_Complex16*</code> for <code>vzArg</code> , <code>vmcArg</code>	Pointer to an array that contains the input vector a .
$mode$	<code>const MKL_INT64</code>	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	<code>float*</code> for <code>vcArg</code> , <code>vmcArg</code> <code>double*</code> for <code>vzArg</code> , <code>vmcArg</code>	Pointer to an array that contains the output vector y .

Description

The `v?Arg` function computes argument of vector elements.

See the [Special Value Notations](#) section for the conventions used in the table below.

Special Values for Complex Function `v?Arg(z)`

$\text{RE}(z)$ $i \cdot \text{IM}(z)$	$-\infty$	$-X$	-0	$+0$	$+X$	$+\infty$	NAN
$+i \cdot \infty$	$+3 \cdot \pi/4$	$+\pi/2$	$+\pi/2$	$+\pi/2$	$+\pi/2$	$+\pi/4$	NAN
$+i \cdot Y$	$+\pi$		$+\pi/2$	$+\pi/2$		$+0$	NAN
$+i \cdot 0$	$+\pi$	$+\pi$	$+\pi$	$+0$	$+0$	$+0$	NAN
$-i \cdot 0$	$-\pi$	$-\pi$	$-\pi$	-0	-0	-0	NAN
$-i \cdot Y$	$-\pi$		$-\pi/2$	$-\pi/2$		-0	NAN
$-i \cdot \infty$	$-3 \cdot \pi/4$	$-\pi/2$	$-\pi/2$	$-\pi/2$	$-\pi/2$	$-\pi/4$	NAN
$+i \cdot \text{NAN}$	NAN	NAN	NAN	NAN	NAN	NAN	NAN

Notes:

- raises `INVALID` exception when real or imaginary part of the argument is `SNAN`
- $\text{Arg}(z) = \text{Atan2}(\text{IM}(z), \text{RE}(z))$.

`v?LinearFrac`

Performs linear fraction transformation of vectors a and b with scalar parameters.

Syntax

```
vsLinearFrac( n, a, b, scalea, shifta, scaleb, shiftb, y );
vmsLinearFrac( n, a, b, scalea, shifta, scaleb, shiftb, y, mode );
vdLinearFrac( n, a, b, scalea, shifta, scaleb, shiftb, y )
vmdLinearFrac( n, a, b, scalea, shifta, scaleb, shiftb, y, mode );
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>n</i>	const MKL_INT	Specifies the number of elements to be calculated.
<i>a, b</i>	const float* for vsLinearFrac, vmsLinearFrac const double* for vdLinearFrac, vmdLinearFrac	Pointers to arrays that contain the input vectors <i>a</i> and <i>b</i> .
<i>scalea, scaleb</i>	const float for vsLinearFrac, vmsLinearFrac const double for vdLinearFrac, vmdLinearFrac	Constant values for shifting addends of vectors <i>a</i> and <i>b</i> .
<i>shifta, shiftb</i>	const float for vsLinearFrac, vmsLinearFrac const double for vdLinearFrac, vmdLinearFrac	Constant values for scaling multipliers of vectors <i>a</i> and <i>b</i> .
<i>mode</i>	const MKL_INT64	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
<i>y</i>	float* for vsLinearFrac, vmsLinearFrac double* for vdLinearFrac, vmdLinearFrac	Pointer to an array that contains the output vector <i>y</i> .

Description

The `v?LinearFrac` function performs linear fraction transformation of vectors *a* by vector *b* with scalar parameters: scaling multipliers *scalea*, *scaleb* and shifting addends *shifta*, *shiftb*:

$$y[i] = (scalea \cdot a[i] + shifta) / (scaleb \cdot b[i] + shiftb), i=1,2 \dots n$$

The `v?LinearFrac` function is implemented in the EP accuracy mode only, therefore no special values are defined for this function. If used in HA or LA mode, `v?LinearFrac` sets the VM Error Status to `VML_STATUS_ACCURACYWARNING` (see the [Values of the VM Status](#) table). Correctness is guaranteed within the threshold limitations defined for each input parameter (see the table below); otherwise, the behavior is unspecified.

Threshold Limitations on Input Parameters

$$2^{E_{\text{MIN}}/2} \leq |scalea| \leq 2^{(E_{\text{MAX}}-2)/2}$$

$$2^{E_{\text{MIN}}/2} \leq |scaleb| \leq 2^{(E_{\text{MAX}}-2)/2}$$

$$|shiftd| \leq 2^{E_{\text{MAX}}-2}$$

$$|shiftd| \leq 2^{E_{\text{MAX}}-2}$$

$$2^{E_{\text{MIN}}/2} \leq a[i] \leq 2^{(E_{\text{MAX}}-2)/2}$$

$$2^{E_{\text{MIN}}/2} \leq b[i] \leq 2^{(E_{\text{MAX}}-2)/2}$$

$$a[i] \neq - (shiftd/scalea) * (1-\delta_1), \quad |\delta_1| \leq 2^{1-(p-1)/2}$$

$$b[i] \neq - (shiftd/scaleb) * (1-\delta_2), \quad |\delta_2| \leq 2^{1-(p-1)/2}$$

E_{MIN} and E_{MAX} are the maximum and minimum exponents and p is the number of significant bits (precision) for corresponding data type according to the ANSI/IEEE Std 754-2008 standard ([IEEE754]):

- for single precision $E_{\text{MIN}} = -126$, $E_{\text{MAX}} = 127$, $p = 24$
- for double precision $E_{\text{MIN}} = -1022$, $E_{\text{MAX}} = 1023$, $p = 53$

The thresholds become less strict for common cases with $scalea=0$ and/or $scaleb=0$:

- if $scalea=0$, there are no limitations for the values of $a[i]$ and $shiftd$
- if $scaleb=0$, there are no limitations for the values of $b[i]$ and $shiftd$

Power and Root Functions

v?Inv

Performs element by element inversion of the vector.

Syntax

```
vsInv( n, a, y );
vmsInv( n, a, y, mode );
vdInv( n, a, y );
vmdInv( n, a, y, mode );
```

Include Files

- `mk1.h`

Input Parameters

Name	Type	Description
<code>n</code>	<code>const MKL_INT</code>	Specifies the number of elements to be calculated.

Name	Type	Description
<i>a</i>	const float* for vsInv, vmsInv const double* for vdInv, vmdInv	Pointer to an array that contains the input vector <i>a</i> .
<i>mode</i>	const MKL_INT64	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
<i>y</i>	float* for vsInv, vmsInv double* for vdInv, vmdInv	Pointer to an array that contains the output vector <i>y</i> .

Description

The *v?Inv* function performs element by element inversion of the vector.

Special Values for Real Function *v?Inv(x)*

Argument	Result	VM Error Status	Exception
+0	$+\infty$	VML_STATUS_SING	ZERODIVIDE
-0	$-\infty$	VML_STATUS_SING	ZERODIVIDE
$+\infty$	+0		
$-\infty$	-0		
QNAN	QNAN		
SNAN	QNAN		INVALID

v?Div

Performs element by element division of vector a by vector b

Syntax

```
vsDiv( n, a, b, y );
vmsDiv( n, a, b, y, mode );
vdDiv( n, a, b, y );
vmdDiv( n, a, b, y, mode );
vcDiv( n, a, b, y );
vmcDiv( n, a, b, y, mode );
vzDiv( n, a, b, y );
vmzDiv( n, a, b, y, mode );
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
n	const MKL_INT	Specifies the number of elements to be calculated.
a, b	const float* for vsDiv, vmsDiv const double* for vdDiv, vmdDiv const MKL_Complex8* for vcDiv, vmcDiv const MKL_Complex16* for vzDiv, vmzDiv	Pointers to arrays that contain the input vectors a and b .
$mode$	const MKL_INT64	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Precision Overflow Thresholds for Real v?Div Function

Data Type	Threshold Limitations on Input Parameters
single precision	$\text{abs}(a[i]) < \text{abs}(b[i]) * \text{FLT\_MAX}$
double precision	$\text{abs}(a[i]) < \text{abs}(b[i]) * \text{DBL\_MAX}$

Precision overflow thresholds for the complex $v?Div$ function are beyond the scope of this document.

Output Parameters

Name	Type	Description
y	float* for vsDiv, vmsDiv double* for vdDiv, vmdDiv MKL_Complex8* for vcDiv, vmcDiv MKL_Complex16* for vzDiv, vmzDiv	Pointer to an array that contains the output vector y .

Description

The $v?Div$ function performs element by element division of vector a by vector b .

Special values for Real Function v?Div(x)

Argument 1	Argument 2	Result	VM Error Status	Exception
$X > +0$	$+0$	$+\infty$	VML_STATUS_SING	ZERODIVIDE
$X > +0$	-0	$-\infty$	VML_STATUS_SING	ZERODIVIDE
$X < +0$	$+0$	$-\infty$	VML_STATUS_SING	ZERODIVIDE
$X < +0$	-0	$+\infty$	VML_STATUS_SING	ZERODIVIDE
$+0$	$+0$	QNAN	VML_STATUS_SING	
-0	-0	QNAN	VML_STATUS_SING	
$X > +0$	$+\infty$	$+0$		
$X > +0$	$-\infty$	-0		
$+\infty$	$+\infty$	QNAN		
$-\infty$	$-\infty$	QNAN		
QNAN	QNAN	QNAN		
SNAN	SNAN	QNAN		INVALID

Specifications for special values of the complex functions are defined according to the following formula

$$\text{Div}(x1+i*y1, x2+i*y2) = (x1+i*y1) * (x2-i*y2) / (x2*x2+y2*y2).$$

Overflow in a complex function occurs when $x2+i*y2$ is not zero, $x1$, $x2$, $y1$, $y2$ are finite numbers, but the real or imaginary part of the exact result is so large that it does not fit the target precision. In that case, the function returns ∞ in that part of the result, raises the `OVERFLOW` exception, and sets the VM Error Status to `VML_STATUS_OVERFLOW`.

v?Sqrt

Computes a square root of vector elements.

Syntax

```
vsSqrt( n, a, y );
vmsSqrt( n, a, y, mode );
vdSqrt( n, a, y );
vmdSqrt( n, a, y, mode );
vcSqrt( n, a, y );
vmcSqrt( n, a, y, mode );
vzSqrt( n, a, y );
vmzSqrt( n, a, y, mode );
```

Include Files

- `mkL.h`

Input Parameters

Name	Type	Description
<i>n</i>	<code>const MKL_INT</code>	Specifies the number of elements to be calculated.
<i>a</i>	<code>const float*</code> for <code>vsSqrt</code> , <code>vmsSqrt</code> <code>const double*</code> for <code>vdSqrt</code> , <code>vmdSqrt</code> <code>const MKL_Complex8*</code> for <code>vcSqrt</code> , <code>vmcSqrt</code> <code>const MKL_Complex16*</code> for <code>vzSqrt</code> , <code>vmzSqrt</code>	Pointer to an array that contains the input vector <i>a</i> .
<i>mode</i>	<code>const MKL_INT64</code>	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
<i>y</i>	<code>float*</code> for <code>vsSqrt</code> , <code>vmsSqrt</code> <code>double*</code> for <code>vdSqrt</code> , <code>vmdSqrt</code> <code>MKL_Complex8*</code> for <code>vcSqrt</code> , <code>vmcSqrt</code>	Pointer to an array that contains the output vector <i>y</i> .

Name	Type	Description

	MKL_Complex16* for vzSqrt, vmzSqrt	

Description

The `v?Sqrt` function computes a square root of vector elements.

Special Values for Real Function `v?Sqrt(x)`

Argument	Result	VM Error Status	Exception
$X < +0$	QNAN	VML_STATUS_ERRDOM	INVALID
$+0$	$+0$		
-0	-0		
$-\infty$	QNAN	VML_STATUS_ERRDOM	INVALID
$+\infty$	$+\infty$

Input Parameters

Name	Type	Description
<i>n</i>	const MKL_INT	Specifies the number of elements to be calculated.
<i>a</i>	const float* for vsInvSqrt, vmsInvSqrt const double* for vdInvSqrt, vmdInvSqrt	Pointer to an array that contains the input vector <i>a</i> .
<i>mode</i>	const MKL_INT64	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
<i>y</i>	float* for vsInvSqrt, vmsInvSqrt double* for vdInvSqrt, vmdInvSqrt	Pointer to an array that contains the output vector <i>y</i> .

Description

The `v?InvSqrt` function computes an inverse square root of vector elements.

Special Values for Real Function `v?InvSqrt(x)`

Argument	Result	VM Error Status	Exception
$X < +0$	QNAN	VML_STATUS_ERRDOM	INVALID
$+0$	$+\infty$	VML_STATUS_SING	ZERODIVIDE
-0	$-\infty$	VML_STATUS_SING	ZERODIVIDE
$-\infty$	QNAN	VML_STATUS_ERRDOM	INVALID
$+\infty$	$+0$		
QNAN	QNAN		
SNAN	QNAN		INVALID

`v?Cbrt`

Computes a cube root of vector elements.

Syntax

```
vsCbrt( n, a, y );
vmsCbrt( n, a, y, mode );
vdCbrt( n, a, y );
vmdCbrt( n, a, y, mode );
```

v?Pow

Computes a to the power b for elements of two vectors.

Syntax

```
vsPow( n, a, b, y );
vmsPow( n, a, b, y, mode );
vdPow( n, a, b, y );
vmdPow( n, a, b, y, mode );
vcPow( n, a, b, y );
vmcPow( n, a, b, y, mode );
vzPow( n, a, b, y );
vmzPow( n, a, b, y, mode );
```

Include Files

- `mk1.h`

Input Parameters

Name	Type	Description
n	<code>const MKL_INT</code>	Specifies the number of elements to be calculated.
a, b	<code>const float*</code> for <code>vsPow</code> , <code>vmsPow</code> <code>const double*</code> for <code>vdPow</code> , <code>vmdPow</code> <code>const MKL_Complex8*</code> for <code>vcPow</code> , <code>vmcPow</code> <code>const MKL_Complex16*</code> for <code>vzPow</code> , <code>vmzPow</code>	Pointers to arrays that contain the input vectors a and b .
$mode$	<code>const MKL_INT64</code>	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Precision Overflow Thresholds for Real $v?Pow$ Function

Data Type	Threshold Limitations on Input Parameters
single precision	$\text{abs}(a[i]) < (\text{FLT\_MAX})^{1/b[i]}$
double precision	$\text{abs}(a[i]) < (\text{DBL\_MAX})^{1/b[i]}$

Precision overflow thresholds for the complex $v?Pow$ function are beyond the scope of this document.

Output Parameters

Name	Type	Description
y	<code>float*</code> for <code>vsPow</code> , <code>vmsPow</code> <code>double*</code> for <code>vdPow</code> , <code>vmdPow</code> <code>MKL_Complex8*</code> for <code>vcPow</code> , <code>vmcPow</code> <code>MKL_Complex16*</code> for <code>vzPow</code> , <code>vmzPow</code>	Pointer to an array that contains the output vector y .

Description

The $v?Pow$ function computes a to the power b for elements of two vectors.

The real function $v(s/d)Pow$ has certain limitations on the input range of a and b parameters. Specifically, if $a[i]$ is positive, then $b[i]$ may be arbitrary. For negative $a[i]$, the value of $b[i]$ must be an integer (either positive or negative).

The complex function $v(c/z)Pow$ has no input range limitations.

Special values for Real Function $v?Pow(x)$

QNaN	QNaN	QNaN		
QNaN	SNAN	QNaN		INVALID
SNAN	QNaN	QNaN		INVALID
SNAN	SNAN	QNaN		INVALID

The complex double precision versions of this function, `vzPow` and `vmzPow`, are implemented in the EP accuracy mode only. If used in HA or LA mode, `vzPow` and `vmzPow` set the VM Error Status to `VML_STATUS_ACCURACYWARNING` (see the [Values of the VM Status](#) table).

Overflow in a complex function occurs (supported in the HA/LA accuracy modes only) when x_1 , x_2 , y_1 , y_2 are finite numbers, but the real or imaginary part of the computed result is so large that it does not fit the target precision. In this case, the function returns ∞ in that part of the result, raises the `OVERFLOW` exception, and sets the VM Error Status to `VML_STATUS_OVERFLOW` (overriding any possible `VML_STATUS_ACCURACYWARNING` status).

v?Powx

Raises each element of a vector to the constant power.

Syntax

```
vsPowx( n, a, b, y );
vmsPowx( n, a, b, y, mode );
vdPowx( n, a, b, y );
vmdPowx( n, a, b, y, mode );
vcPowx( n, a, b, y );
vmcPowx( n, a, b, y, mode );
vzPowx( n, a, b, y );
vmzPowx( n, a, b, y, mode );
```

Include Files

- `mk1.h`

Input Parameters

Name	Type	Description
n	<code>const MKL_INT</code>	Number of elements to be calculated.
a	<code>const float*</code> for <code>vsPowx</code> , <code>vmsPowx</code> <code>const double*</code> for <code>vdPowx</code> , <code>vmdPowx</code> <code>const MKL_Complex8*</code> for <code>vcPowx</code> , <code>vmcPowx</code> <code>const MKL_Complex16*</code> for <code>vzPowx</code> , <code>vmzPowx</code>	Pointer to an array that contains the input vector a .
b	<code>const float</code> for <code>vsPowx</code> , <code>vmsPowx</code> <code>const double</code> for <code>vdPowx</code> , <code>vmdPowx</code>	Constant value for power b .

Name	Type	Description
	const MKL_Complex8 for vcPowx, vmcPowx	
	const MKL_Complex16 for vzPowx, vmzPowx	
mode	const MKL_INT64	Overrides global VM mode setting for this function call. See vm1SetMode for possible values and their description.

Precision Overflow Thresholds for Real v?Powx Function

Data Type	Threshold Limitations on Input Parameters
single precision	$\text{abs}(a[i]) < (\text{FLT\_MAX})^{1/b}$
double precision	$\text{abs}(a[i]) < (\text{DBL\_MAX})^{1/b}$

Precision overflow thresholds for the complex v?Powx function are beyond the scope of this document.

Output Parameters

Name	Type	Description
y	float* for vsPowx, vmsPowx double* for vdPowx, vmdPowx MKL_Complex8* for vcPowx, vmcPowx MKL_Complex16* for vzPowx, vmzPowx	Pointer to an array that contains the output vector y.

Description

The v?Powx function raises each element of a vector to the constant power.

The real function v(s/d)Powx has certain limitations on the input range of a and b parameters. Specifically, if a[i] is positive, then b may be arbitrary. For negative a[i], the value of b must be an integer (either positive or negative).

The complex function v(c/z)Powx has no input range limitations.

Special values and VM Error Status treatment are the same as for the v?Pow function.

v?Hypot

Computes a square root of sum of two squared elements.

Syntax

```
vsHypot( n, a, b, y );
vmsHypot( n, a, b, y, mode );
vdHypot( n, a, b, y );
vmdHypot( n, a, b, y, mode );
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
n	const MKL_INT	Number of elements to be calculated.
a, b	const float* for vsHypot, vmsHypot const double* for vdHypot, vmdHypot	Pointers to arrays that contain the input vectors a and b .
$mode$	const MKL_INT64	Overrides global VM mode setting for this function call. See vm1SetMode for possible values and their description.

Precision Overflow Thresholds for Hypot Function

Data Type	Threshold Limitations on Input Parameters
single precision	$\text{abs}(a[i]) < \text{sqrt}(\text{FLT\_MAX})$ $\text{abs}(b[i]) < \text{sqrt}(\text{FLT\_MAX})$
double precision	$\text{abs}(a[i]) < \text{sqrt}(\text{DBL\_MAX})$ $\text{abs}(b[i]) < \text{sqrt}(\text{DBL\_MAX})$

Output Parameters

Name	Type	Description
y	float* for vsHypot, vmsHypot double* for vdHypot, vmdHypot	Pointer to an array that contains the output vector y .

Description

The function `v?Hypot` computes a square root of sum of two squared elements.

Special values for Real Function `v?Hypot(x)`

Argument 1	Argument 2	Result	Exception
+0	+0	+0	
-0	-0	+0	
$+\infty$	any value	$+\infty$	
any value	$+\infty$	$+\infty$	
SNAN	any value	QNAN	INVALID
any value	SNAN	QNAN	INVALID
QNAN	any value	QNAN	
any value	QNAN	QNAN	

Exponential and Logarithmic Functions

`v?Exp`

Computes an exponential of vector elements.

Syntax

```

vsExp( n, a, y );
vmsExp( n, a, y, mode );
vdExp( n, a, y );
vmdExp( n, a, y, mode );
vcExp( n, a, y );
vmcExp( n, a, y, mode );
vzExp( n, a, y );
vmzExp( n, a, y, mode );

```

Include Files

- `mkl.h`

Input Parameters

Name	Type	Description
<i>n</i>	<code>const MKL_INT</code>	Specifies the number of elements to be calculated.
<i>a</i>	<code>const float*</code> for <code>vsExp</code> , <code>vmsExp</code> <code>const double*</code> for <code>vdExp</code> , <code>vmdExp</code> <code>const MKL_Complex8*</code> for <code>vcExp</code> , <code>vmcExp</code> <code>const MKL_Complex16*</code> for <code>vzExp</code> , <code>vmzExp</code>	Pointer to an array that contains the input vector <i>a</i> .
<i>mode</i>	<code>const MKL_INT64</code>	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Precision Overflow Thresholds for Real v?Exp Function

Data Type	Threshold Limitations on Input Parameters
single precision	$a[i] < \ln(\text{FLT\_MAX})$
double precision	$a[i] < \ln(\text{DBL\_MAX})$

Precision overflow thresholds for the complex `v?Exp` function are beyond the scope of this document.

Output Parameters

Name	Type	Description
<i>y</i>	<code>float*</code> for <code>vsExp</code> , <code>vmsExp</code> <code>double*</code> for <code>vdExp</code> , <code>vmdExp</code> <code>MKL_Complex8*</code> for <code>vcExp</code> , <code>vmcExp</code> <code>MKL_Complex16*</code> for <code>vzExp</code> , <code>vmzExp</code>	Pointer to an array that contains the output vector <i>y</i> .

Description

The `v?Exp` function computes an exponential of vector elements.

Special Values for Real Function $v?Exp(x)$

Argument	Result	VM Error Status	Exception
+0	+1		
-0	+1		
$X > \text{overflow}$	$+\infty$	VML_STATUS_OVERFLOW	OVERFLOW
$X < \text{underflow}$	+0	VML_STATUS_UNDERFLOW	UNDERFLOW
$+\infty$	$+\infty$		
$-\infty$	+0		
QNAN	QNAN		
SNAN	QNAN		INVALID

See the [Special Value Notations](#) section for the conventions used in the table below.

Special Values for Complex Function $v?Exp(z)$

$RE(z)$ $i \cdot IM(z)$	$-\infty$	-X	-0	+0	+X	$+\infty$	NAN
$+i \cdot \infty$	+0+i·0	QNAN+i·QNAN INVALID	QNAN+i·QNAN INVALID	QNAN+i·QNAN INVALID	QNAN+i·QNAN INVALID	$+\infty+i \cdot \text{QNAN}$ INVALID	QNAN+i·QNAN INVALID
$+i \cdot Y$	+0·CIS(Y)					$+\infty \cdot \text{CIS}(Y)$	QNAN+i·QNAN
$+i \cdot 0$	+0·CIS(0)		+1+i·0	+1+i·0		$+\infty+i \cdot 0$	QNAN+i·0
$-i \cdot 0$	+0·CIS(0)		+1-i·0	+1-i·0		$+\infty-i \cdot 0$	QNAN-i·0
$-i \cdot Y$	+0·CIS(Y)					$+\infty \cdot \text{CIS}(Y)$	QNAN+i·QNAN
$-i \cdot \infty$	+0-i·0	QNAN+i·QNAN INVALID	QNAN+i·QNAN INVALID	QNAN+i·QNAN INVALID	QNAN+i·QNAN INVALID	$+\infty+i \cdot \text{QNAN}$ INVALID	QNAN+i·QNAN
$+i \cdot \text{NAN}$	+0+i·0	QNAN+i·QNAN INVALID	QNAN+i·QNAN INVALID	QNAN+i·QNAN INVALID	QNAN+i·QNAN INVALID	$+\infty+i \cdot \text{QNAN}$	QNAN+i·QNAN

Notes:

- raises the `INVALID` exception when real or imaginary part of the argument is `SNAN`
- raises the `INVALID` exception on argument $z = -\infty + i \cdot \text{QNAN}$
- raises the `OVERFLOW` exception and sets the VM Error Status to `VML_STATUS_OVERFLOW` in the case of overflow, that is, when $RE(z)$, $IM(z)$ are finite non-zero numbers, but the real or imaginary part of the exact result is so large that it does not meet the target precision.

$v?Exp m1$

Computes an exponential of vector elements decreased by 1.

Syntax

```
vsExp m1 ( n, a, y );
vmsExp m1 ( n, a, y, mode );
vdExp m1 ( n, a, y );
vmdExp m1 ( n, a, y, mode );
```

Include Files

- `mk1.h`

Input Parameters

Name	Type	Description
<i>n</i>	const MKL_INT	Specifies the number of elements to be calculated.
<i>a</i>	const float* for vsExpml, vmsExpml const double* for vdExpml, vmdExpml	Pointer to an array that contains the input vector <i>a</i> .
<i>mode</i>	const MKL_INT64	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Precision Overflow Thresholds for Expml Function

Data Type	Threshold Limitations on Input Parameters
single precision	$a[i] < \text{Ln}(\text{FLT\_MAX})$
double precision	$a[i] < \text{Ln}(\text{DBL\_MAX})$

Output Parameters

Name	Type	Description
<i>y</i>	float* for vsExpml, vmsExpml double* for vdExpml, vmdExpml	Pointer to an array that contains the output vector <i>y</i> .

Description

The `v?Expml` function computes an exponential of vector elements decreased by 1.

Special Values for Real Function `v?Expml(x)`

Argument	Result	VM Error Status	Exception

Input Parameters

Name	Type	Description
<i>n</i>	const MKL_INT	Specifies the number of elements to be calculated.

Name	Type	Description
<i>a</i>	const float* for vsLog10, vmsLog10 const double* for vdLog10, vmdLog10 const MKL_Complex8* for vcLog10, vmcLog10 const MKL_Complex16* for vzLog10, vmzLog10	Pointer to an array that contains the input vector <i>a</i> .
<i>mode</i>	const MKL_INT64	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
<i>y</i>	float* for vsLog10, vmsLog10 double* for vdLog10, vmdLog10 MKL_Complex8* for vcLog10, vmcLog10 MKL_Complex16* for vzLog10, vmzLog10	Pointer to an array that contains the output vector <i>y</i> .

Description

The `v?Log10` function computes a denary logarithm of vector elements.

v?Log1p

Computes a natural logarithm of vector elements that are increased by 1.

Syntax

```
vsLog1p( n, a, y );
vmsLog1p( n, a, y, mode );
vdLog1p( n, a, y );
vmdLog1p( n, a, y, mode );
```

Include Files

- mk1.h

Input Parameters

Name	Type	Description
<i>n</i>	const MKL_INT	Specifies the number of elements to be calculated.
<i>a</i>	const float* for vsLog1p, vmsLog1p const double* for vdLog1p, vmdLog1p	Pointer to an array that contains the input vector <i>a</i> .

Name	Type	Description
<i>mode</i>	const MKL_INT64	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
<i>y</i>	float* for vsLog1p, vmsLog1p double* for vdLog1p, vmdLog1p	Pointer to an array that contains the output vector <i>y</i> .

Description

The `v?Log1p` function computes a natural logarithm of vector elements that are increased by 1.

Special Values for Real Function `v?Log1p(x)`

Argument	Result	VM Error Status	Exception
-1	$-\infty$	VML_STATUS_SING	ZERODIVIDE
$X < -1$	QNAN	VML_STATUS_ERRDOM	INVALID
+0	+0		
-0	-0		
$-\infty$	QNAN	VML_STATUS_ERRDOM	INVALID
$+\infty$	$+\infty$		
QNAN	QNAN		
SNAN	QNAN		INVALID

Trigonometric Functions

`v?Cos`

Computes cosine of vector elements.

Syntax

```
vsCos( n, a, y );
vmsCos( n, a, y, mode );
vdCos( n, a, y );
vmdCos( n, a, y, mode );
vcCos( n, a, y );
vmcCos( n, a, y, mode );
vzCos( n, a, y );
vmzCos( n, a, y, mode );
```

Include Files

- `mk1.h`

Input Parameters

Name	Type	Description
<i>n</i>	const MKL_INT	Specifies the number of elements to be calculated.
<i>a</i>	const float* for vsCos, vmsCos const double* for vdCos, vmdCos const MKL_Complex8* for vcCos, vmcCos const MKL_Complex16* for vzCos, vmzCos	Pointer to an array that contains the input vector <i>a</i> .
<i>mode</i>	const MKL_INT64	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
<i>y</i>	float* for vsCos, vmsCos double* for vdCos, vmdCos MKL_Complex8* for vcCos, vmcCos MKL_Complex16* for vzCos, vmzCos	Pointer to an array that contains the output vector <i>y</i> .

Description

The *v?Cos* function computes cosine of vector elements.

Note that arguments $\text{abs}(a[i]) \leq 2^{13}$ and $\text{abs}(a[i]) \leq 2^{16}$ for single and double precisions respectively are called fast computational path. These are trigonometric function arguments for which VM provides the best possible performance. Avoid arguments that do not belong to the fast computational path in the VM High Accuracy (HA) and Low Accuracy (LA) functions. Alternatively, you can use VM Enhanced Performance (EP) functions that are fast on the entire function domain. However, these functions provide less accuracy.

Special Values for Real Function *v?Cos(x)*

Argument	Result	VM Error Status	Exception
+0	+1		
-0	+1		
$+\infty$	QNAN	VML_STATUS_ERRDOM	INVALID
$-\infty$	QNAN	VML_STATUS_ERRDOM	INVALID
QNAN	QNAN		
SNAN	QNAN		INVALID

Specifications for special values of the complex functions are defined according to the following formula

$$\text{Cos}(z) = \text{Cosh}(i*z).$$

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

v?Sin

Computes sine of vector elements.

Syntax

```
vsSin( n, a, y );
vmsSin( n, a, y, mode );
vdSin( n, a, y );
vmdSin( n, a, y, mode );
vcSin( n, a, y );
vmcSin( n, a, y, mode );
vzSin( n, a, y );
vmzSin( n, a, y, mode );
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>n</i>	const MKL_INT	Specifies the number of elements to be calculated.
<i>a</i>	const float* for vsSin, vmsSin const double* for vdSin, vmdSin const MKL_Complex8* for vcSin, vmcSin const MKL_Complex16* for vzSin, vmzSin	Pointer to an array that contains the input vector <i>a</i> .
<i>mode</i>	const MKL_INT64	Overrides global VM mode setting for this function call. See vm1SetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	<code>float*</code> for <code>vsSin</code> , <code>vmsSin</code>	Pointer to an array that contains the output vector y .
	<code>double*</code> for <code>vdSin</code> , <code>vmdSin</code>	
	<code>MKL_Complex8*</code> for <code>vcSin</code> , <code>vmcSin</code>	
	<code>MKL_Complex16*</code> for <code>vzSin</code> , <code>vmzSin</code>	

Description

The function computes sine of vector elements.

Note that arguments $\text{abs}(a[i]) \leq 2^{13}$ and $\text{abs}(a[i]) \leq 2^{16}$ for single and double precisions respectively are called fast computational path. These are trigonometric function arguments for which VM provides the best possible performance. Avoid arguments that do not belong to the fast computational path in the VM High Accuracy (HA) and Low Accuracy (LA) functions. Alternatively, you can use VM Enhanced Performance (EP) functions that are fast on the entire function domain. However, these functions provide less accuracy.

Notice revision #20110804

$v?SinCos$

Computes sine and cosine of vector elements.

Syntax

```
vsSinCos( n, a, y, z );
vmsSinCos( n, a, y, z, mode );
vdSinCos( n, a, y, z );
vmdSinCos( n, a, y, z, mode );
```

Include Files

- `mk1.h`

Input Parameters

Name	Type	Description
n	<code>const MKL_INT</code>	Specifies the number of elements to be calculated.
a	<code>const float*</code> for <code>vsSinCos</code> , <code>vmsSinCos</code> <code>const double*</code> for <code>vdSinCos</code> , <code>vmdSinCos</code>	Pointer to an array that contains the input vector a .
$mode$	<code>const MKL_INT64</code>	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y, z	<code>float*</code> for <code>vsSinCos</code> , <code>vmsSinCos</code> <code>double*</code> for <code>vdSinCos</code> , <code>vmdSinCos</code>	Pointers to arrays that contain the output vectors y (for sine values) and z (for cosine values).

Description

The function computes sine and cosine of vector elements.

Note that arguments $\text{abs}(a[i]) \leq 2^{13}$ and $\text{abs}(a[i]) \leq 2^{16}$ for single and double precisions respectively are called fast computational path. These are trigonometric function arguments for which VM provides the best possible performance. Avoid arguments that do not belong to the fast computational path in the VM High Accuracy (HA) and Low Accuracy (LA) functions. Alternatively, you can use VM Enhanced Performance (EP) functions that are fast on the entire function domain. However, these functions provide less accuracy.

Optimization Notice

optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

v?CIS

Computes complex exponent of real vector elements (cosine and sine of real vector elements combined to complex value).

Syntax

```
vcCIS( n, a, y );
vmcCIS( n, a, y, mode );
vzCIS( n, a, y );
vmzCIS( n, a, y, mode );
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>n</i>	const MKL_INT	Specifies the number of elements to be calculated.
<i>a</i>	const float* for vcCIS, vmcCIS const double* for vzCIS, vmzCIS	Pointer to an array that contains the input vector <i>a</i> .
<i>mode</i>	const MKL_INT64	Overrides global VM mode setting for this function call. See vm1SetMode for possible values and their description.

Output Parameters

Name	Type	Description
<i>y</i>	MKL_Complex8* for vcCIS, vmcCIS MKL_Complex16* for vzCIS, vmzCIS	Pointer to an array that contains the output vector <i>y</i> .

Description

The v?CIS function computes complex exponent of real vector elements (cosine and sine of real vector elements combined to complex value).

See the [Special Value Notations](#) section for the conventions used in the table below.

Special Values for Complex Function v?CIS(x)

x	CIS(x)
$+\infty$	QNAN+i·QNAN

x	CIS(x)
	INVALID
+ 0	+1+i·0
- 0	+1-i·0
- ∞	QNAN+i·QNAN INVALID
NAN	QNAN+i·QNAN

Notes:

- raises `INVALID` exception when the argument is `SNAN`
- raises `INVALID` exception and sets the VM Error Status to `VML_STATUS_ERRDOM` for $x=+\infty$, $x=-\infty$

v?Tan

Computes tangent of vector elements.

Syntax

```
vsTan( n, a, y );
vmsTan( n, a, y, mode );
vdTan( n, a, y );
vmdTan( n, a, y, mode );
vcTan( n, a, y );
vmcTan( n, a, y, mode );
vzTan( n, a, y );
vmzTan( n, a, y, mode );
```

Include Files

- `mk1.h`

Input Parameters

Name	Type	Description
<i>n</i>	<code>const MKL_INT</code>	Specifies the number of elements to be calculated.
<i>a</i>	<code>const float*</code> for <code>vsTan</code> , <code>vmsTan</code> <code>const double*</code> for <code>vdTan</code> , <code>vmdTan</code> <code>const MKL_Complex8*</code> for <code>vcTan</code> , <code>vmcTan</code> <code>const MKL_Complex16*</code> for <code>vzTan</code> , <code>vmzTan</code>	Pointer to an array that contains the input vector <i>a</i> .

Name	Type	Description
<i>mode</i>	const MKL_INT64	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
<i>y</i>	float* for vsTan, vmsTan double* for vdTan, vmdTan MKL_Complex8* for vcTan, vmcTan MKL_Complex16* for vzTan, vmzTan	Pointer to an array that contains the output vector <i>y</i> .

Description

The *v?Tan* function computes tangent of vector elements.

Note that arguments $\text{abs}(a[i]) \leq 2^{13}$ and $\text{abs}(a[i]) \leq 2^{16}$ for single and double precisions respectively are called fast computational path. These are trigonometric function arguments for which VM provides the best possible performance. Avoid arguments that do not belong to the fast computational path in the VM High Accuracy (HA) and Low Accuracy (LA) functions. Alternatively, you can use VM Enhanced Performance (EP) functions that are fast on the entire function domain. However, these functions provide less accuracy.

Special Values for Real Function *v?Tan(x)*

Argument	Result	VM Error Status	Exception
+0	+0		
-0	-0		
$+\infty$	QNAN	VML_STATUS_ERRDOM	INVALID
$-\infty$	QNAN	VML_STATUS_ERRDOM	INVALID
QNAN	QNAN		
SNAN	QNAN		INVALID

Specifications for special values of the complex functions are defined according to the following formula

$$\text{Tan}(z) = -i * \text{Tanh}(i * z).$$

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

v?Acos

Computes inverse cosine of vector elements.

Syntax

```
vsAcos( n, a, y );
```

```

vmsAcos( n, a, y, mode );
vdAcos( n, a, y );
vmdAcos( n, a, y, mode );
vcAcos( n, a, y );
vmcAcos( n, a, y, mode );
vzAcos( n, a, y );
vmzAcos( n, a, y, mode );

```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>n</i>	const int	Specifies the number of elements to be calculated.
<i>a</i>	const float* for vsAcos, vmsAcos const double* for vdAcos, vmdAcos const MKL_Complex8* for vcAcos, vmcAcos const MKL_Complex16* for vzAcos, vmzAcos	Pointer to an array that contains the input vector <i>a</i> .
<i>mode</i>	const MKL_INT64	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
<i>y</i>	float* for vsAcos, vmsAcos double* for vdAcos, vmdAcos MKL_Complex8* for vcAcos, vmcAcos MKL_Complex16* for vzAcos, vmzAcos	Pointer to an array that contains the output vector <i>y</i> .

Description

The `v?Acos` function computes inverse cosine of vector elements.

Notes:

- raises INVALID exception when real or imaginary part of the argument is SNAN
- $Acos(CONJ(z)) = CONJ(Acos(z))$.

$v?Asin$

Computes inverse sine of vector elements.

Syntax

```
vsAsin( n, a, y );
vmsAsin( n, a, y, mode );
vdAsin( n, a, y );
vmdAsin( n, a, y, mode );
vcAsin( n, a, y );
vmcAsin( n, a, y, mode );
vzAsin( n, a, y );
vmzAsin( n, a, y, mode );
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>n</i>	const MKL_INT	Specifies the number of elements to be calculated.
<i>a</i>	const float* for vsAsin, vmsAsin const double* for vdAsin, vmdAsin const MKL_Complex8* for vcAsin, vmcAsin const MKL_Complex16* for vzAsin, vmzAsin	Pointer to an array that contains the input vector <i>a</i> .
<i>mode</i>	const MKL_INT64	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
<i>y</i>	float* for vsAsin, vmsAsin double* for vdAsin, vmdAsin MKL_Complex8* for vcAsin, vmcAsin MKL_Complex16* for vzAsin, vmzAsin	Pointer to an array that contains the output vector <i>y</i> .

Description

The `v?Asin` function computes inverse sine of vector elements.

Special Values for Real Function `v?Asin(x)`

Argument	Result	VM Error Status	Exception
+0	+0		
-0	-0		
+1	$+\pi/2$		
-1	$-\pi/2$		
$ X > 1$	QNAN	VML_STATUS_ERRDOM	INVALID
$+\infty$	QNAN	VML_STATUS_ERRDOM	INVALID

QNAN	QNAN		
SNAN	QNAN		INVALID

Specifications for special values of the complex functions are defined according to the following formula

$$\text{Asin}(z) = -i * \text{Asinh}(i * z).$$

`v?Atan`

Computes inverse tangent of vector elements.

Syntax

```
vsAtan( n, a, y );
```

```

vmsAtan( n, a, y, mode );
vdAtan( n, a, y );
vmdAtan( n, a, y, mode );
vcAtan( n, a, y );
vmcAtan( n, a, y, mode );
vzAtan( n, a, y );
vmzAtan( n, a, y, mode );

```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>n</i>	const MKL_INT	Specifies the number of elements to be calculated.
<i>a</i>	const float* for vsAtan, vmsAtan const double* for vdAsin, vmdAtan const MKL_Complex8* for vcAtan, vmcAtan const MKL_Complex16* for vzAsin, vmzAtan	Pointer to an array that contains the input vector <i>a</i> .
<i>mode</i>	const MKL_INT64	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
<i>y</i>	float* for vsAtan, vmsAtan double* for vdAsin, vmdAtan MKL_Complex8* for vcAtan, vmcAtan MKL_Complex16* for vzAsin, vmzAtan	Pointer to an array that contains the output vector <i>y</i> .

Description

The `v?Atan` function computes inverse tangent of vector elements.

Special Values for Real Function `v?Atan(x)`

Argument	Result	VM Error Status	Exception
+0	+0		
-0	-0		
$+\infty$	$+\pi/2$		
$-\infty$	$-\pi/2$		
QNAN	QNAN		

Argument	Result	VM Error Status	Exception
SNAN	QNAN		INVALID

Specifications for special values of the complex functions are defined according to the following formula

$$\text{Atan}(z) = -i * \text{Atanh}(i * z).$$

v?Atan2

Computes four-quadrant inverse tangent of elements of two vectors.

Syntax

```
vsAtan2( n, a, b, y );
vmsAtan2( n, a, b, y, mode );
vdAtan2( n, a, b, y );
vmdAtan2( n, a, b, y, mode );
```

Include Files

- `mk1.h`

Input Parameters

Name	Type	Description
<i>n</i>	<code>const MKL_INT</code>	Specifies the number of elements to be calculated.
<i>a, b</i>	<code>const float*</code> for <code>vsAtan2</code> , <code>vmsAtan2</code> <code>const double*</code> for <code>vdAtan2</code> , <code>vmdAtan2</code>	Pointers to arrays that contain the input vectors <i>a</i> and <i>b</i> .
<i>mode</i>	<code>const MKL_INT64</code>	Overrides global VM mode setting for this function call. See vm1SetMode for possible values and their description.

Output Parameters

Name	Type	Description
<i>y</i>	<code>float*</code> for <code>vsAtan2</code> , <code>vmsAtan2</code> <code>double*</code> for <code>vdAtan2</code> , <code>vmdAtan2</code>	Pointer to an array that contains the output vector <i>y</i> .

Description

The `v?Atan2` function computes four-quadrant inverse tangent of elements of two vectors.

The elements of the output vector *y* are computed as the four-quadrant arctangent of $a[i] / b[i]$.

Hyperbolic Functions

v?Cosh

Computes hyperbolic cosine of vector elements.

Syntax

```
vsCosh( n, a, y );
```

```
vmsCosh( n, a, y, mode );
```

```

vdCosh( n, a, y );
vmdCosh( n, a, y, mode );
vcCosh( n, a, y );
vmcCosh( n, a, y, mode );
vzCosh( n, a, y );
vmzCosh( n, a, y, mode );

```

Include Files

- `mk1.h`

Input Parameters

Name	Type	Description
<i>n</i>	<code>const MKL_INT</code>	Specifies the number of elements to be calculated.
<i>a</i>	<code>const float*</code> for <code>vsCosh</code> , <code>vmsCosh</code> <code>const double*</code> for <code>vdCosh</code> , <code>vmdCosh</code> <code>const MKL_Complex8*</code> for <code>vcCosh</code> , <code>vmcCosh</code> <code>const MKL_Complex16*</code> for <code>vzCosh</code> , <code>vmzCosh</code>	Pointer to an array that contains the input vector <i>a</i> .
<i>mode</i>	<code>const MKL_INT64</code>	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Precision Overflow Thresholds for Real `v?Cosh` Function

Data Type	Threshold Limitations on Input Parameters
single precision	$-\ln(\text{FLT\_MAX}) - \ln 2 < a[i] < \ln(\text{FLT\_MAX}) + \ln 2$
double precision	$-\ln(\text{DBL\_MAX}) - \ln 2 < a[i] < \ln(\text{DBL\_MAX}) + \ln 2$

Precision overflow thresholds for the complex `v?Cosh` function are beyond the scope of this document.

Output Parameters

Name	Type	Description
<i>y</i>	<code>float*</code> for <code>vsCosh</code> , <code>vmsCosh</code> <code>double*</code> for <code>vdCosh</code> , <code>vmdCosh</code> <code>MKL_Complex8*</code> for <code>vcCosh</code> , <code>vmcCosh</code> <code>MKL_Complex16*</code> for <code>vzCosh</code> , <code>vmzCosh</code>	Pointer to an array that contains the output vector <i>y</i> .

Description

The `v?Cosh` function computes hyperbolic cosine of vector elements.

Special Values for Real Function v?Cosh(x)

Argument	Result	VM Error Status	Exception
+0	+1		
-0	+1		
X > overflow	$+\infty$	VML_STATUS_OVERFLOW	OVERFLOW
X < -overflow	$+\infty$	VML_STATUS_OVERFLOW	OVERFLOW
$+\infty$	$+\infty$		
$-\infty$	$+\infty$		
QNAN	QNAN		
SNAN	QNAN		INVALID

See the [Special Value Notations](#) section for the conventions used in the table below.

Special Values for Complex Function v?Cosh(z)

RE(z) i·IM(z)	$-\infty$	-X	-0	+0	+X	$+\infty$	NAN
$+i\cdot\infty$	$+\infty+i\cdot\text{QNAN}$ INVALID	QNAN+i·QNAN INVALID	QNAN-i·0 INVALID	QNAN+i·0 INVALID	QNAN+i·QNAN INVALID	$+\infty+i\cdot\text{QNAN}$ INVALID	QNAN+i·QNAN
$+i\cdot Y$	$+\infty\cdot\text{Cos}(Y)-i\cdot\infty\cdot\text{Sin}(Y)$					$+\infty\cdot\text{CIS}(Y)$	QNAN+i·QNAN
$+i\cdot 0$	$+\infty-i\cdot 0$		$+1-i\cdot 0$	$+1+i\cdot 0$		$+\infty+i\cdot 0$	QNAN+i·0
$-i\cdot 0$	$+\infty+i\cdot 0$		$+1+i\cdot 0$	$+1-i\cdot 0$		$+\infty-i\cdot 0$	QNAN-i·0
$-i\cdot Y$	$+\infty\cdot\text{Cos}(Y)-i\cdot\infty\cdot\text{Sin}(Y)$					$+\infty\cdot\text{CIS}(Y)$	QNAN+i·QNAN
$-i\cdot\infty$	$+\infty+i\cdot\text{QNAN}$ INVALID	QNAN+i·QNAN INVALID	QNAN+i·0 INVALID	QNAN-i·0 INVALID	QNAN+i·QNAN INVALID	$+\infty+i\cdot\text{QNAN}$ INVALID	QNAN+i·QNAN
$+i\cdot\text{NAN}$	$+\infty+i\cdot\text{QNAN}$	QNAN+i·QNAN	QNAN+i·QNAN	QNAN-i·QNAN	QNAN+i·QNAN	$+\infty+i\cdot\text{QNAN}$	QNAN+i·QNAN

Notes:

- raises the `INVALID` exception when the real or imaginary part of the argument is `SNAN`
- raises the `OVERFLOW` exception and sets the VM Error Status to `VML_STATUS_OVERFLOW` in the case of overflow, that is, when $\text{RE}(z)$, $\text{IM}(z)$ are finite non-zero numbers, but the real or imaginary part of the exact result is so large that it does not meet the target precision.
- $\text{Cosh}(\text{CONJ}(z)) = \text{CONJ}(\text{Cosh}(z))$
- $\text{Cosh}(-z) = \text{Cosh}(z)$.

v?Sinh

Computes hyperbolic sine of vector elements.

Syntax

```
vsSinh( n, a, y );
```

```
vmsSinh( n, a, y, mode );
```

```
vdSinh( n, a, y );
```

```
vmdSinh( n, a, y, mode );
```

```
vcSinh( n, a, y );
```

```
vmcSinh( n, a, y, mode );
```

```

vzSinh( n, a, y );
vmzSinh( n, a, y, mode );

```

Include Files

- `mk1.h`

Input Parameters

Name	Type	Description
<i>n</i>	<code>const MKL_INT</code>	Specifies the number of elements to be calculated.
<i>a</i>	<code>const float*</code> for <code>vsSinh</code> , <code>vmsSinh</code> <code>const double*</code> for <code>vdSinh</code> , <code>vmdSinh</code> <code>const MKL_Complex8*</code> for <code>vcSinh</code> , <code>vmcSinh</code> <code>const MKL_Complex16*</code> for <code>vzSinh</code> , <code>vmzSinh</code>	Pointer to an array that contains the input vector <i>a</i> .
<i>mode</i>	<code>const MKL_INT64</code>	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Precision Overflow Thresholds for Real `v?Sinh` Function

Data Type	Threshold Limitations on Input Parameters
single precision	$-\ln(\text{FLT\_MAX}) - \ln 2 < a[i] < \ln(\text{FLT\_MAX}) + \ln 2$
double precision	$-\ln(\text{DBL\_MAX}) - \ln 2 < a[i] < \ln(\text{DBL\_MAX}) + \ln 2$

Precision overflow thresholds for the complex `v?Sinh` function are beyond the scope of this document.

Output Parameters

Name	Type	Description
<i>y</i>	<code>float*</code> for <code>vsSinh</code> , <code>vmsSinh</code> <code>double*</code> for <code>vdSinh</code> , <code>vmdSinh</code> <code>MKL_Complex8*</code> for <code>vcSinh</code> , <code>vmcSinh</code> <code>MKL_Complex16*</code> for <code>vzSinh</code> , <code>vmzSinh</code>	Pointer to an array that contains the output vector <i>y</i> .

Description

The `v?Sinh` function computes hyperbolic sine of vector elements.

Special Values for Real Function `v?Sinh(x)`

Argument	Result	VM Error Status	Exception
+0	+0		
-0	-0		
$X > \text{overflow}$	$+\infty$	<code>VML_STATUS_OVERFLOW</code>	OVERFLOW
$X < -\text{overflow}$	$-\infty$	<code>VML_STATUS_OVERFLOW</code>	OVERFLOW
$+\infty$	$+\infty$		

Argument	Result	VM Error Status	Exception
$-\infty$	$-\infty$		
QNAN	QNAN		
SNAN	QNAN		INVALID

See the [Special Value Notations](#) section for the conventions used in the table below.

Special Values for Complex Function $v?Sinh(z)$

$RE(z)$ $i \cdot IM(z)$	$-\infty$	$-X$	-0	$+0$	$+X$	$+\infty$	NAN
$+i \cdot \infty$	$-\infty+i \cdot QNAN$ INVALID	QNAN+i·QNAN INVALID	$-0+i \cdot QNAN$ INVALID	$+0+i \cdot QNAN$ INVALID	QNAN+i·QNAN INVALID	$+\infty+i \cdot QNAN$ INVALID	QNAN+i·QNAN
$+i \cdot Y$	$-\infty \cdot \cos(Y) + i \cdot \infty \cdot \sin(Y)$					$+\infty \cdot \text{CIS}(Y)$	QNAN+i·QNAN
$+i \cdot 0$	$-\infty+i \cdot 0$		$-0+i \cdot 0$	$+0+i \cdot 0$		$+\infty+i \cdot 0$	QNAN+i·0
$-i \cdot 0$	$-\infty-i \cdot 0$		$-0-i \cdot 0$	$+0-i \cdot 0$		$+\infty-i \cdot 0$	QNAN-i·0
$-i \cdot Y$	$-\infty \cdot \cos(Y) + i \cdot \infty \cdot \sin(Y)$					$+\infty \cdot \text{CIS}(Y)$	QNAN+i·QNAN
$-i \cdot \infty$	$-\infty+i \cdot QNAN$ INVALID	QNAN+i·QNAN INVALID	$-0+i \cdot QNAN$ INVALID	$+0+i \cdot QNAN$ INVALID	QNAN+i·QNAN INVALID	$+\infty+i \cdot QNAN$ INVALID	QNAN+i·QNAN
$+i \cdot \text{NAN}$	$-\infty+i \cdot QNAN$	QNAN+i·QNAN	$-0+i \cdot QNAN$	$+0+i \cdot QNAN$	QNAN+i·QNAN	$+\infty+i \cdot QNAN$	QNAN+i·QNAN

Notes:

- raises the `INVALID` exception when the real or imaginary part of the argument is `SNAN`
- raises the `OVERFLOW` exception and sets the VM Error Status to `VML_STATUS_OVERFLOW` in the case of overflow, that is, when $RE(z)$, $IM(z)$ are finite non-zero numbers, but the real or imaginary part of the exact result is so large that it does not meet the target precision.
- $\sinh(\text{CONJ}(z)) = \text{CONJ}(\sinh(z))$
- $\sinh(-z) = -\sinh(z)$.

$v?Tanh$

Computes hyperbolic tangent of vector elements.

Syntax

```
vsTanh( n, a, y );
```

```
vmsTanh( n, a, y, mode );
```

```
vdTanh( n, a, y );
```

```
vmdTanh( n, a, y, mode );
```

```
vcTanh( n, a, y );
```

```
vmcTanh( n, a, y, mode );
```

```
vzTanh( n, a, y );
```

```
vmzTanh( n, a, y, mode );
```

Include Files

- `mk1.h`

Input Parameters

Name	Type	Description
n	<code>const MKL_INT</code>	Specifies the number of elements to be calculated.
a	<code>const float*</code> for <code>vsTanh</code> , <code>vmsTanh</code> <code>const double*</code> for <code>vdTanh</code> , <code>vmdTanh</code> <code>const MKL_Complex8*</code> for <code>vcTanh</code> , <code>vmcTanh</code> <code>const MKL_Complex16*</code> for <code>vzTanh</code> , <code>vmzTanh</code>	Pointer to an array that contains the input vector a .
$mode$	<code>const MKL_INT64</code>	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	<code>float*</code> for <code>vsTanh</code> , <code>vmsTanh</code> <code>double*</code> for <code>vdTanh</code> , <code>vmdTanh</code> <code>MKL_Complex8*</code> for <code>vcTanh</code> , <code>vmcTanh</code> <code>MKL_Complex16*</code> for <code>vzTanh</code> , <code>vmzTanh</code>	Pointer to an array that contains the output vector y .

Description

The `v?Tanh` function computes hyperbolic tangent of vector elements.

Special Values for Real Function `v?Tanh(x)`

Argument	Result	Exception
+0	+0	
-0	-0	
$+\infty$	+1	
$-\infty$	-1	
QNAN	QNAN

- $\text{Tanh}(\text{CONJ}(z)) = \text{CONJ}(\text{Tanh}(z))$
- $\text{Tanh}(-z) = -\text{Tanh}(z)$.

v?Acosh

Computes inverse hyperbolic cosine (nonnegative) of vector elements.

Syntax

```
vsAcosh( n, a, y );
vmsAcosh( n, a, y, mode );
vdAcosh( n, a, y );
vmdAcosh( n, a, y, mode );
vcAcosh( n, a, y );
vmcAcosh( n, a, y, mode );
vzAcosh( n, a, y );
vmzAcosh( n, a, y, mode );
```

Include Files

- `mk1.h`

Input Parameters

Name	Type	Description
<i>n</i>	<code>const MKL_INT</code>	Specifies the number of elements to be calculated.
<i>a</i>	<code>const float*</code> for <code>vsAcosh</code> , <code>vmsAcosh</code> <code>const double*</code> for <code>vdAcosh</code> , <code>vmdAcosh</code> <code>const MKL_Complex8*</code> for <code>vcAcosh</code> , <code>vmcAcosh</code>	Pointer to an array that contains the input vector <i>a</i> .

Name	Type	Description
	const MKL_Complex16* for vzAcosh, vmzAcosh	
mode	const MKL_INT64	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y	float* for vsAcosh, vmsAcosh double* for vdAcosh, vmdAcosh MKL_Complex8* for vcAcosh, vmcAcosh MKL_Complex16* for vzAcosh, vmzAcosh	Pointer to an array that contains the output vector y.

Description

The `v?Acosh` function computes inverse hyperbolic cosine (nonnegative) of vector elements.

Special Values for Real Function v?Acosh(x)

Argument	Result	VM Error Status	Exception
+1	+0		
$X < +1$	QNAN	VML_STATUS_ERRDOM	INVALID
$-\infty$	QNAN	VML_STATUS_ERRDOM	INVALID
$+\infty$	$+\infty$		
QNAN	QNAN

Notes:

- raises `INVALID` exception when real or imaginary part of the argument is `SNAN`
- $\text{Asinh}(\text{CONJ}(z)) = \text{CONJ}(\text{Asinh}(z))$
- $\text{Asinh}(-z) = -\text{Asinh}(z)$.

v?Atanh

Computes inverse hyperbolic tangent of vector elements.

Syntax

```
vsAtanh( n, a, y );
```

```
vmsAtanh( n, a, y, mode );
```

```
vdAtanh( n, a, y );
```

```
vmdAtanh( n, a, y, mode );
```

```
vcAtanh( n, a, y );
```

```
vmcAtanh( n, a, y, mode );
vzAtanh( n, a, y );
vmzAtanh( n, a, y, mode );
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>n</i>	const MKL_INT	Specifies the number of elements to be calculated.
<i>a</i>	const float* for vsAtanh, vmsAtanh const double* for vdAtanh, vmdAtanh const MKL_Complex8* for vcAtanh, vmcAtanh const MKL_Complex16* for vzAtanh, vmzAtanh	Pointer to an array that contains the input vector <i>a</i> .
<i>mode</i>	const MKL_INT64	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
<i>y</i>	float* for vsAtanh, vmsAtanh double* for vdAtanh, vmdAtanh MKL_Complex8* for vcAtanh, vmcAtanh MKL_Complex16* for vzAtanh, vmzAtanh	Pointer to an array that contains the output vector <i>y</i> .

Description

The `v?Atanh` function computes inverse hyperbolic tangent of vector elements.

Special Values for Real Function `v?Atanh(x)`

Argument	Result	VM Error Status	Exception
+1	$+\infty$	VML_STATUS_SING	ZERODIVIDE
-1	$-\infty$	VML_STATUS_SING	ZERODIVIDE
$ X > 1$	QNaN	VML_STATUS_ERRDOM	INVALID
$+\infty$	QNaN	VML_STATUS_ERRDOM	INVALID
$-\infty$	QNaN	VML_STATUS_ERRDOM	INVALID
QNaN	QNaN		
SNAN	QNaN		INVALID

See the [Special Value Notations](#) section for the conventions used in the table below.

Special Values for Complex Function $v\text{?Atanh}(z)$

RE(z) i·IM(z)	$-\infty$	-X	-0	+0	+X	$+\infty$	NAN
$+i\cdot\infty$	$-0+i\cdot\pi/2$	$-0+i\cdot\pi/2$	$-0+i\cdot\pi/2$	$+0+i\cdot\pi/2$	$+0+i\cdot\pi/2$	$+0+i\cdot\pi/2$	$+0+i\cdot\pi/2$
$+i\cdot Y$	$-0+i\cdot\pi/2$					$+0+i\cdot\pi/2$	QNAN+i·QNAN
$+i\cdot 0$	$-0+i\cdot\pi/2$		$-0+i\cdot 0$	$+0+i\cdot 0$		$+0+i\cdot\pi/2$	QNAN+i·QNAN
$-i\cdot 0$	$-0-i\cdot\pi/2$		$-0-i\cdot 0$	$+0-i\cdot 0$		$+0-i\cdot\pi/2$	QNAN-i·QNAN

Input Parameters

Name	Type	Description
<code>n</code>	<code>const MKL_INT</code>	Specifies the number of elements to be calculated.
<code>a</code>	<code>const float*</code> for <code>vsErf</code> , <code>vmsErf</code> <code>const double*</code> for <code>vdErf</code> , <code>vmdErf</code>	Pointer to an array that contains the input vector <code>a</code> .

Name	Type	Description
<i>mode</i>	const MKL_INT64	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
<i>y</i>	float* for vsErf, vmsErf double* for vdErf, vmdErf	Pointer to an array that contains the output vector <i>y</i> .

Description

The `Erf` function computes the error function values for elements of the input vector *a* and writes them to the output vector *y*.

The error function is defined as given by:

$$\text{erf}(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt .$$

Useful relations:

$$1. \quad \text{erfc}(x) = 1 - \text{erf}(x) ,$$

where `erfc` is the complementary error function.

$$2. \quad \Phi(x) = \frac{1}{2} \text{erf} (x/\sqrt{2}) ,$$

where

$$\Phi(x) = \frac{1}{\sqrt{2\pi}} \int_0^x \exp (- t^2/2) dt$$

is the cumulative normal distribution function.

$$3. \quad \Phi^{-1}(x) = \sqrt{2} \text{erf}^{-1}(2x - 1) ,$$

where $\Phi^{-1}(x)$ and $\text{erf}^{-1}(x)$ are the inverses to $\Phi(x)$ and $\text{erf}(x)$ respectively.

The following figure illustrates the relationships among `Erf` family functions (`Erf`, `Erfc`, `CdfNorm`).

Erf Family Functions Relationship

Useful relations for these functions:

$\text{erf}(x) + \text{erfc}(x) = 1$

$\text{cdfnorm}(x) = \frac{1}{2} \left(1 + \text{erf} \left(\frac{x}{\sqrt{2}} \right) \right) = 1 - \frac{1}{2} \text{erfc} \left(\frac{x}{\sqrt{2}} \right)$

v?Erfc

Computes the complementary error function value of vector elements.

Syntax

```
vsErfc( n, a, y );  
vmsErfc( n, a, y, mode );  
vdErfc( n, a, y );  
vmdErfc( n, a, y, mode );
```

Include Files

- `mkl.h`

Input Parameters

Name	Type	Description
<i>n</i>	<code>const MKL_INT</code>	Specifies the number of elements to be calculated.
<i>a</i>	<code>const float*</code> for <code>vsErfc</code> , <code>vmsErfc</code> <code>const double*</code> for <code>vdErfc</code> , <code>vmdErfc</code>	Pointer to an array that contains the input vector <i>a</i> .
<i>mode</i>	<code>const MKL_INT64</code>	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
<i>y</i>	<code>float*</code> for <code>vsErfc</code> , <code>vmsErfc</code> <code>double*</code> for <code>vdErfc</code> , <code>vmdErfc</code>	Pointer to an array that contains the output vector <i>y</i> .

Description

The `Erfc` function computes the complementary error function values for elements of the input vector *a* and writes them to the output vector *y*.

The complementary error function is defined as follows:

$$\operatorname{erfc}(x) = 1 - \operatorname{erf}(x)$$

Useful relations:

$$1. \quad \operatorname{erfc}(x) = 1 - \operatorname{erf}(x).$$

$$2. \quad \Phi(x) = \frac{1}{2} \operatorname{erf}(x/\sqrt{2}),$$

where

$$\Phi(x) = \frac{1}{\sqrt{2\pi}} \int_0^x \exp(-t^2/2) dt$$

is the cumulative normal distribution function.

$$3. \quad \Phi^{-1}(x) = \sqrt{2} \operatorname{erf}^{-1}(2x - 1),$$

where $\Phi^{-1}(x)$ and $\operatorname{erf}^{-1}(x)$ are the inverses to $\Phi(x)$ and $\operatorname{erf}(x)$ respectively.

<i>n</i>	<code>const MKL_INT</code>	Specifies the number of elements to be calculated.
<i>a</i>	<code>const float*</code> for <code>vsCdfNorm</code> , <code>vmsCdfNorm</code> <code>const double*</code> for <code>vdCdfNorm</code> , <code>vmdCdfNorm</code>	Pointer to an array that contains the input vector <i>a</i> .
<i>mode</i>	<code>const MKL_INT64</code>	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
<i>y</i>	<code>float*</code> for <code>vsCdfNorm</code> , <code>vmsCdfNorm</code> <code>double*</code> for <code>vdCdfNorm</code> , <code>vmdCdfNorm</code>	Pointer to an array that contains the output vector <i>y</i> .

Description

The `CdfNorm` function computes the cumulative normal distribution function values for elements of the input vector *a* and writes them to the output vector *y*.

The cumulative normal distribution function is defined as given by:

$$\text{CdfNorm}(x) = \frac{1}{\sqrt{2\pi}} \int_{-\infty}^x e^{-\frac{t^2}{2}} dt .$$

Useful relations:

$$\text{cdfnorm}(x) = \frac{1}{2} \left(1 + \text{erf} \left(\frac{x}{\sqrt{2}} \right) \right) = 1 - \frac{1}{2} \text{erfc} \left(\frac{x}{\sqrt{2}} \right)$$

where `Erf` and `Erfc` are the error and complementary error functions.

Output Parameters

Name	Type	Description
<i>y</i>	float* for vsErfInv, vmsErfInv double* for vdErfInv, vmdErfInv	Pointer to an array that contains the output vector <i>y</i> .

Description

The `ErfInv` function computes the inverse error function values for elements of the input vector *a* and writes them to the output vector *y*

$$y = \text{erf}^{-1}(a),$$

where `erf(x)` is the error function defined as given by:

$$\text{erf}(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt .$$

Useful relations:

$$1. \quad \text{erf}^{-1}(x) = \text{erfc}^{-1}(1 - x),$$

where `erfc` is the complementary error function.

$$2. \quad \Phi(x) = \frac{1}{2} \text{erf} (x/\sqrt{2}),$$

where

$$\Phi(x) = \frac{1}{\sqrt{2\pi}} \int_0^x \exp (- t^2/2) dt$$

is the cumulative normal distribution function.

$$3. \Phi^{-1}(x) = \sqrt{2} \operatorname{erf}^{-1}(2x - 1),$$

where $\Phi^{-1}(x)$ and $\operatorname{erf}^{-1}(x)$ are the inverses to $\Phi(x)$ and $\operatorname{erf}(x)$ respectively.

Figure "ErfInv Family Functions Relationship" illustrates the relationships among ErfInv family functions (ErfInv, ErfcInv, CdfNormInv).

ErfInv Family Functions Relationship

Useful relations for these functions:

$$\operatorname{erfcinv}(x) = \operatorname{erfinv}(1 - x)$$

$$\operatorname{cdfnorminv}(x) = \sqrt{2} \operatorname{erfinv}(2x - 1) = \sqrt{2} \operatorname{erfcinv}(2 - 2x)$$

Description

The `ErfcInv` function computes the inverse complimentary error function values for elements of the input vector *a* and writes them to the output vector *y*.

The inverse complementary error function is defined as given by:

$$\operatorname{erfcinv}(x) = \operatorname{erfinv}(1 - x)$$

$$\operatorname{erfinv}(x) = \operatorname{erf}^{-1}(x)$$

$$\operatorname{erf}(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt$$

where $\operatorname{erf}(x)$ denotes the error function and $\operatorname{erfinv}(x)$ denotes the inverse error function.

See also [Figure "ErfInv Family Functions Relationship"](#) in `ErfInv` function description for `ErfcInv` function relationship with the other functions of `ErfInv` family.

Output Parameters

Name	Type	Description
<i>y</i>	float* for vsCdfNormInv, vmsCdfNormInv double* for vdCdfNormInv, vmdCdfNormInv	Pointer to an array that contains the output vector <i>y</i> .

Description

The `CdfNormInv` function computes the inverse cumulative normal distribution function values for elements of the input vector *a* and writes them to the output vector *y*.

The inverse cumulative normal distribution function is defined as given by:

$$\text{CdfNormInv}(x) = \text{CdfNorm}^{-1}(x) ,$$

where $\text{CdfNorm}(x)$ denotes the cumulative normal distribution function.

Useful relations:

$$\text{cdfnorminv}(x) = \sqrt{2}\text{erfinv}(2x - 1) = \sqrt{2}\text{erfcinv}(2 - 2x)$$

where $\text{erfinv}(x)$ denotes the inverse error function and $\text{erfcinv}(x)$ denotes the inverse complementary error functions.

`v?Rint`

Computes a rounded integer value in the current rounding mode.

Syntax

```
vsRint( n, a, y );
vmsRint( n, a, y, mode );
vdRint( n, a, y );
vmdRint( n, a, y, mode );
```

Include Files

- `mk1.h`

Input Parameters

Name	Type	Description
<i>n</i>	const MKL_INT	Specifies the number of elements to be calculated.
<i>a</i>	const float* for vsRint, vmsRint const double* for vdRint, vmdRint	Pointer to an array that contains the input vector <i>a</i> .
<i>mode</i>	const MKL_INT64	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
<i>y</i>	float* for vsRint, vmsRint double* for vdRint, vmdRint	Pointer to an array that contains the output vector <i>y</i> .

Description

The `v?Rint` function computes a rounded floating-point integer value using the current rounding mode for each vector element.

The rounding mode affects the results computed for inputs that fall between consecutive integers. For example:

- $f(0.5) = 0$, for rounding modes set to round to nearest round toward zero or to minus infinity.
- $f(0.5) = 1$, for rounding modes set to plus infinity.
- $f(-1.5) = -2$, for rounding modes set to round to nearest or to minus infinity.
- $f(-1.5) = -1$, for rounding modes set to round toward zero or to plus infinity.

Special Values for Real Function `v?Rint(x)`

Argument	Result	Exception
+0	+0	
-0	-0	
$+\infty$	$+\infty$	
$-\infty$	$-\infty$	
SNAN	QNAN	INVALID
QNAN	QNAN	

`v?Modf`

Computes a truncated integer value and the remaining fraction part for each vector element.

Syntax

```
vsModf( n, a, y, z );
vmsModf( n, a, y, z, mode );
vdModf( n, a, y, z );
vmdModf( n, a, y, z, mode );
```

Include Files

Input Parameters

Name	Type	Description
n	<code>const MKL_INT</code>	Specifies the number of elements to be calculated.
a	<code>const float*</code> for <code>vsModf</code> , <code>vmsModf</code> <code>const double*</code> for <code>vdModf</code> , <code>vmdModf</code>	Pointer to an array that contains the input vector a .
$mode$	<code>const MKL_INT64</code>	Overrides global VM mode setting for this function call. See vmlSetMode for possible values and their description.

Output Parameters

Name	Type	Description
y, z	<code>float*</code> for <code>vsModf</code> , <code>vmsModf</code> <code>double*</code> for <code>vdModf</code> , <code>vmdModf</code>	Pointer to an array that contains the output vector y and z .

Description

The function computes a truncated integer value and the remaining fraction part for each vector element.

$$a_i \geq 0, \begin{cases} y_i = \lfloor a_i \rfloor \\ z_i = a_i - \lfloor a_i \rfloor \end{cases}$$

$$a_i < 0, \begin{cases} y_i = \lceil a_i \rceil \\ z_i = a_i - \lceil a_i \rceil \end{cases}$$

Special Values for Real Function `v?Modf(x)`

Argument	Result: $y(i)$	Result: $z(i)$	Exception

QNAN	QNAN	QNAN	

`v?Frac`

Computes a signed fractional part for each vector element.

Syntax

```
vsFrac( n, a, y );
```

```
vmsFrac( n, a, y, mode );
```

```
vdFrac( n, a, y );
```

```
vmdFrac( n, a, y, mode );
```

Include Files

- `mkL.h`

Input Parameters

Name	Type	Description
<i>n</i>	<code>const MKL_INT</code>	Specifies the number of elements to be calculated.
<i>a</i>	<code>const float*</code> for <code>vsFrac</code> , <code>vmsFrac</code> <code>const double*</code> for <code>vdFrac</code> , <code>vmdFrac</code>	Pointer to an array that contains the input vector <i>a</i> .
<i>mode</i>	<code>const MKL_INT64</code>	Overrides global VM mode setting for this function call. See vmLSetMode for possible values and their description.

Output Parameters

Name	Type	Description
<i>y</i>	<code>float*</code> for <code>vsFrac</code> , <code>vmsFrac</code> <code>double*</code> for <code>vdFrac</code> , <code>vmdFrac</code>	Pointer to an array that contains the output vector <i>y</i> .

Description

The function computes a signed fractional part for each vector element.

$$y_i = \begin{cases} a_i - \lfloor a_i \rfloor, & a_i \geq 0 \\ a_i - \lceil a_i \rceil, & a_i < 0 \end{cases}$$

VM Pack/Unpack Functions

This section describes VM functions that convert vectors with unit increment to and from vectors with positive increment indexing, vector indexing, and mask indexing (see Appendix B for details on vector indexing methods).

The table below lists available VM Pack/Unpack functions, together with data types and indexing methods associated with them.

VM Pack/Unpack Functions

Function Short Name	Data Types	Indexing Methods	Description
<code>v?Pack</code>	<code>s, d, c, z</code>	<code>I, V, M</code>	Gathers elements of arrays, indexed by different methods.
<code>v?Unpack</code>	<code>s, d, c, z</code>	<code>I, V, M</code>	Scatters vector elements to arrays with different indexing.

See Also

Vector Arguments in VM

v?Pack

Copies elements of an array with specified indexing to a vector with unit increment.

Syntax

```
vsPackI( n, a, inca, y );
vsPackV( n, a, ia, y );
vsPackM( n, a, ma, y );
vdPackI( n, a, inca, y );
vdPackV( n, a, ia, y );
vdPackM( n, a, ma, y );
vcPackI( n, a, inca, y );
vcPackV( n, a, ia, y );
vcPackM( n, a, ma, y );
vzPackI( n, a, inca, y );
vzPackV( n, a, ia, y );
vzPackM( n, a, ma, y );
```

Include Files

- `mk1.h`

Input Parameters

Name	Type	Description
<code>n</code>	<code>const MKL_INT</code>	Specifies the number of elements to be calculated.
<code>a</code>	<code>const float*</code> for <code>vsPackI</code> , <code>vsPackV</code> , <code>vsPackM</code> <code>const double*</code> for <code>vdPackI</code> , <code>vdPackV</code> , <code>vdPackM</code> <code>const MKL_Complex8*</code> for <code>vcPackI</code> , <code>vcPackV</code> , <code>vcPackM</code>	Specifies pointer to an array that contains the input vector <code>a</code> . The arrays must be: for <code>v?PackI</code> , at least $(1 + (n-1) * inca)$ for <code>v?PackV</code> , at least $\max(n, \max(ia[j]))$, $j=0, \dots, n-1$ for <code>v?PackM</code> , at least n .

Name	Type	Description
	const MKL_Complex16* for vzPackI, vzPackV, vzPackM	
<i>inca</i>	const MKL_INT for vsPackI, vdPackI, vcPackI, vzPackI	Specifies the increment for the elements of <i>a</i> .
<i>ia</i>	const int* for vsPackV, vdPackV, vcPackV, vzPackV	Specifies the pointer to an array of size at least <i>n</i> that contains the index vector for the elements of <i>a</i> .
<i>ma</i>	const int* for vsPackM, vdPackM, vcPackM, vzPackM	Specifies the pointer to an array of size at least <i>n</i> that contains the mask vector for the elements of <i>a</i> .

Output Parameters

Name	Type	Description
<i>y</i>	float* for vsPackI, vsPackV, vsPackM double* for vdPackI, vdPackV, vdPackM const MKL_Complex8* for vcPackI, vcPackV, vcPackM const MKL_Complex16* for vzPackI, vzPackV, vzPackM	Pointer to an array of size at least <i>n</i> that contains the output vector <i>y</i> .

v?Unpack

Copies elements of a vector with unit increment to an array with specified indexing.

Syntax

```
vsUnpackI( n, a, y, incy );
vsUnpackV( n, a, y, iy );
vsUnpackM( n, a, y, my );
vdUnpackI( n, a, y, incy );
vdUnpackV( n, a, y, iy );
vdUnpackM( n, a, y, my );
vcUnpackI( n, a, y, incy );
vcUnpackV( n, a, y, iy );
vcUnpackM( n, a, y, my );
vzUnpackI( n, a, y, incy );
vzUnpackV( n, a, y, iy );
vzUnpackM( n, a, y, my );
```

Include Files

- `mk1.h`

Input Parameters

Name	Type	Description
n	<code>const MKL_INT</code>	Specifies the number of elements to be calculated.
a	<code>const float* for vsUnpackI,</code> <code>vsUnpackV, vsUnpackM</code> <code>const double* for vdUnpackI,</code> <code>vdUnpackV, vdUnpackM</code> <code>const MKL_Complex8* for</code> <code>vcUnpackI, vcUnpackV, vcUnpackM</code> <code>const MKL_Complex16* for</code> <code>vzUnpackI, vzUnpackV, vzUnpackM</code>	Specifies the pointer to an array of size at least n that contains the input vector a .
$incy$	<code>const MKL_INT for vsUnpackI,</code> <code>vdUnpackI, vcUnpackI, vzUnpackI</code>	Specifies the increment for the elements of y .
iy	<code>const int* for vsUnpackV,</code> <code>vdUnpackV, vcUnpackV, vzUnpackV</code>	Specifies the pointer to an array of size at least n that contains the index vector for the elements of a .
my	<code>const int* for vsUnpackM,</code> <code>vdUnpackM, vcUnpackM, vzUnpackM</code>	Specifies the pointer to an array of size at least n that contains the mask vector for the elements of a .

Output Parameters

Name	Type	Description
y	<code>float* for vsUnpackI, vsUnpackV,</code> <code>vsUnpackM</code> <code>double* for vdUnpackI,</code> <code>vdUnpackV, vdUnpackM</code> <code>const MKL_Complex8* for</code> <code>vcUnpackI, vcUnpackV, vcUnpackM</code> <code>const MKL_Complex16* for</code> <code>vzUnpackI, vzUnpackV, vzUnpackM</code>	Specifies the pointer to an array that contains the output vector y. The array must be: for $v?UnpackI$, at least $(1 + (n-1)*incy)$ for $v?UnpackV$, at least $\max(n, \max(ia[j]), j=0, \dots, n-1,$ for $v?UnpackM$, at least n.

VM Service Functions

The VM Service functions enable you to set/get the accuracy mode and error code. These functions are available both in the Fortran and C interfaces. The table below lists available VM Service functions and their short description.

VM Service Functions

Function Short Name	Description
<code>vm1SetMode</code>	Sets the VM mode

Function Short Name	Description
<code>vmlGetMode</code>	Gets the VM mode
<code>MKLFreeTls</code>	Frees allocated VM/VS thread local storage memory from within DllMain routine (Windows* OS only)
<code>vmlSetErrStatus</code>	Sets the VM Error Status
<code>vmlGetErrStatus</code>	Gets the VM Error Status
<code>vmlClearErrStatus</code>	Clears the VM Error Status
<code>vmlSetErrorCallback</code>	Sets the additional error handler callback function
<code>vmlGetErrorCallback</code>	Gets the additional error handler callback function
<code>vmlClearErrorCallback</code>	Deletes the additional error handler callback function

Optimization Notice

Notice revision #20110804

vmlSetMode

Sets a new mode for VM functions according to the *mode* parameter and stores the previous VM mode to *oldmode*.

Syntax

```
oldmode = vmlSetMode( mode );
```

Include Files

- `mkl.h`

Input Parameters

Name	Type	Description
<i>mode</i>	<code>const MKL_UINT</code>	Specifies the VM mode to be set.

Output Parameters

Name	Type	Description
<i>oldmode</i>	<code>unsigned int</code>	Specifies the former VM mode.

Description

The `vmlSetMode` function sets a new mode for VM functions according to the *mode* parameter and stores the previous VM mode to *oldmode*. The mode change has a global effect on all the VM functions within a thread.

NOTE

You can override the global mode setting and change the mode for a given VM function call by using a respective `vm[s,d]<Func>` variant of the function.

The *mode* parameter is designed to control accuracy, handling of denormalized numbers, and error handling. Table "Values of the *mode* Parameter" lists values of the *mode* parameter. You can obtain all other possible values of the *mode* parameter from the *mode* parameter values by using bitwise OR (`|`) operation to combine one value for accuracy, one value for handling of denormalized numbers, and one value for error control options. The default value of the *mode* parameter is `VML_HA | VML_FTZDAZ_OFF | VML_ERRMODE_DEFAULT`.

The `VML_FTZDAZ_ON` mode is specifically designed to improve the performance of computations that involve denormalized numbers at the cost of reasonable accuracy loss. This mode changes the numeric behavior of the functions: denormalized input values are treated as zeros (`DAZ` = denormals-are-zero) and denormalized results are flushed to zero (`FTZ` = flush-to-zero). Accuracy loss may occur if input and/or output values are close to denormal range.

Values of the *mode* Parameter

Value of <i>mode</i>	Description
Accuracy Control	
<code>VML_HA</code>	high accuracy versions of VM functions
<code>VML_LA</code>	low accuracy versions of VM functions
<code>VML_EP</code>	enhanced performance accuracy versions of VM functions
Denormalized Numbers Handling Control	
<code>VML_FTZDAZ_ON</code>	Faster processing of denormalized inputs is enabled.
<code>VML_FTZDAZ_OFF</code>	Faster processing of denormalized inputs is disabled.
Error Mode Control	
<code>VML_ERRMODE_IGNORE</code>	No action is set for computation errors.
<code>VML_ERRMODE_ERRNO</code>	On error, the <i>errno</i> variable is set.
<code>VML_ERRMODE_STDERR</code>	On error, the error text information is written to <i>stderr</i> .
<code>VML_ERRMODE_EXCEPT</code>	On error, an exception is raised.
<code>VML_ERRMODE_CALLBACK</code>	On error, an additional error handler function is called.
<code>VML_ERRMODE_DEFAULT</code>	On error, the <i>errno</i> variable is set, an exception is raised, and an additional error handler function is called.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Examples

The following example shows how to set low accuracy, fast processing for denormalized numbers and *stderr* error mode:

```
vmlSetMode( VML_LA );
vmlSetMode( VML_LA | VML_FTZDAZ_ON | VML_ERRMODE_STDERR );
```

vmlGetMode

Gets the VM mode.

Syntax

```
mod = vmlGetMode( void );
```

Include Files

- mkl.h

Output Parameters

Name	Type	Description
<i>mod</i>	unsigned int	Specifies the packed <i>mode</i> parameter.

Description

The function `vmlGetMode` returns the VM *mode* parameter that controls accuracy, handling of denormalized numbers, and error handling options. The *mod* variable value is a combination of the values listed in the table "Values of the *mode* Parameter". You can obtain these values using the respective mask from the table "Values of Mask for the *mode* Parameter".

Values of Mask for the *mode* Parameter

Value of mask	Description
VML_ACCURACY_MASK	Specifies mask for accuracy <i>mode</i> selection.
VML_FTZDAZ_MASK	Specifies mask for FTZDAZ <i>mode</i> selection.
VML_ERRMODE_MASK	Specifies mask for error <i>mode</i> selection.

See example below:

Examples

```
accm = vmlGetMode(void ) & VML_ACCURACY_MASK;  
denm = vmlGetMode(void ) & VML_FTZDAZ_MASK;  
errm = vmlGetMode(void ) & VML_ERRMODE_MASK;
```

MKLFreeTls

Frees allocated VM/VS thread local storage memory from within DllMain routine. Use on Windows OS only.*

Syntax

```
void MKLFreeTls( const MKL_UINT fdwReason );
```

Include Files

- mkl_vml_functions_win.h

Description

The `MKLFreeTls` routine frees thread local storage (TLS) memory which has been allocated when using MKL static libraries to link into a DLL on the Windows* OS. The routine should only be used within `DllMain`.

NOTE

It is only necessary to use `MKLFreeTls` for TLS data in the VM and VS domains.

Input Parameters

Name	Type	Description
<i>fdwReason</i>	<code>const MKL_UINT</code>	Reason code from the <code>DllMain</code> call.

Example

```

BOOL WINAPI DllMain(HINSTANCE hInst, DWORD fdwReason, LPVOID lpvReserved)
{
    /*customer code*/
    MKLFreeTls(fdwReason);
    /*customer code*/
}

```

vmlSetErrStatus

Sets the new VM Error Status according to `err` and stores the previous VM Error Status to `olderr`.

Syntax

```
olderr = vmlSetErrStatus( status );
```

Include Files

- `mk1.h`

Input Parameters

Name	Type	Description
<i>status</i>	<code>const MKL_INT</code>	Specifies the VM error status to be set.

Output Parameters

Name	Type	Description
<i>olderr</i>	<code>int</code>	Specifies the former VM error status.

Description

Table "Values of the VM Status" lists possible values of the *err* parameter.

Values of the VM Status

Status	Description
Successful Execution	
<code>VML_STATUS_OK</code>	The execution was completed successfully.
Warnings	
<code>VML_STATUS_ACCURACYWARNING</code>	The execution was completed successfully in a different accuracy mode.
Errors	

Status	Description
VML_STATUS_BADSIZE	The function does not support the preset accuracy mode. The Low Accuracy mode is used instead.
VML_STATUS_BADMEM	NULL pointer is passed.
VML_STATUS_ERRDOM	At least one of array values is out of a range of definition.
VML_STATUS_SING	At least one of the input array values causes a divide-by-zero exception or produces an invalid (QNaN) result.
VML_STATUS_OVERFLOW	An overflow has happened during the calculation process.
VML_STATUS_UNDERFLOW	An underflow has happened during the calculation process.

Examples

```
olderr = vmlSetErrStatus( VML_STATUS_OK );
```

```
olderr = vmlSetErrStatus( VML_STATUS_ERRDOM );
```

```
olderr = vmlSetErrStatus( VML_STATUS_UNDERFLOW );
```

vmlGetErrStatus

Gets the VM Error Status.

Syntax

```
err = vmlGetErrStatus( void );
```

Include Files

- mkl.h

Output Parameters

Name	Type	Description
<i>err</i>	int	Specifies the VM error status.

vmlClearErrStatus

Sets the VM Error Status to VML_STATUS_OK and stores the previous VM Error Status to olderr.

Syntax

```
olderr = vmlClearErrStatus( void );
```

Include Files

- mkl.h

Output Parameters

Name	Type	Description
<i>olderr</i>	int	Specifies the former VM error status.

vmlSetErrorCallback

Sets the additional error handler callback function and gets the old callback function.

Syntax

```
oldcallback = vmlSetErrorCallBack( callback );
```

Include Files

- mkl.h

Input Parameters

Name

callback

Pointer to the callback function.

Description

The callback function has the following format:

```
static int __stdcall
MyHandler(DefVmlErrorContext*
pContext)
{
    /* Handler body */
};
```

The passed error structure is defined as follows:

```
typedef struct _DefVmlErrorContext
{
    int iCode; /* Error status value */
    int iIndex; /* Index for bad array
                element, or bad array
                dimension, or bad
                array pointer */
    double dbA1; /* Error argument 1 */
    double dbA2; /* Error argument 2 */
    double dbR1; /* Error result 1 */
    double dbR2; /* Error result 2 */
    char cFuncName[64]; /* Function name */
    int iFuncNameLen; /* Length of functionname*/
    double dbA1Im; /* Error argument 1, imag part*/
    double dbA2Im; /* Error argument 2, imag part*/
    double dbR1Im; /* Error result 1, imag part*/
    double dbR2Im; /* Error result 2, imag part*/
} DefVmlErrorContext;
```

Output Parameters

Name	Type	Description
<i>oldcallback</i>	int	Pointer to the former callback function.

Description

The callback function is called on each VM mathematical function error if `VML_ERRMODE_CALLBACK` error mode is set (see "Values of the *mode* Parameter").

Use the `vmlSetErrorCallBack()` function if you need to define your own callback function instead of default empty callback function.

The input structure for a callback function contains the following information about the error encountered:

- the input value that caused an error
- location (array index) of this value
- the computed result value
- error code
- name of the function in which the error occurred.

You can insert your own error processing into the callback function. This may include correcting the passed result values in order to pass them back and resume computation. The standard error handler is called after the callback function only if it returns 0.

vmlGetErrorCallBack

Gets the additional error handler callback function.

Syntax

```
callback = vmlGetErrorCallBack( void );
```

Include Files

- `mkl.h`

Output Parameters

Name	Description
<i>callback</i>	Pointer to the callback function

vmlClearErrorCallBack

Deletes the additional error handler callback function and retrieves the former callback function.

Syntax

```
oldcallback = vmlClearErrorCallBack( void );
```

Include Files

- `mkl.h`

Output Parameters

Name	Type	Description
<i>oldcallback</i>	int	Pointer to the former callback function

Statistical Functions

Statistical functions in Intel® MKL are known as the Vector Statistics (VS). They are designed for the purpose of

- generating vectors of pseudorandom, quasi-random, and non-deterministic random numbers
- performing mathematical operations of convolution and correlation
- computing basic statistical estimates for single and double precision multi-dimensional datasets

The corresponding functionality is described in the respective [Random Number Generators](#), [Convolution and Correlation](#), and [Summary Statistics](#) sections.

See VS performance data in the online VS Performance Data document available at <http://software.intel.com/en-us/articles/intel-math-kernel-library-documentation/>

The basic notion in VS is a task. The task object is a data structure or descriptor that holds the parameters related to a specific statistical operation: random number generation, convolution and correlation, or summary statistics estimation. Such parameters can be an identifier of a random number generator, its internal state and parameters, data arrays, their shape and dimensions, an identifier of the operation and so forth. You can modify the VS task parameters using the VS service functions.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Random Number Generators

Intel MKL VS provides a set of routines implementing commonly used pseudorandom, quasi-random, or non-deterministic random number generators with continuous and discrete distribution. To improve performance, all these routines were developed using the calls to the highly optimized *Basic Random Number Generators* (BRNGs) and vector mathematical functions (VM, see [Chapter 9, "Vector Mathematical Functions"](#)).

VS provides interfaces both for Fortran and C languages. For users of the C and C++ languages the `mkl_vs1.h` header file is provided. All header files are found in the following directory:

```
${MKL}/include
```

All VS routines can be classified into three major categories:

- Transformation routines for different types of statistical distributions, for example, uniform, normal (Gaussian), binomial, etc. These routines indirectly call basic random number generators, which are pseudorandom, quasi-random, or non-deterministic random number generators. Detailed description of the generators can be found in [Distribution Generators](#) section.
- Service routines to handle random number streams: create, initialize, delete, copy, save to a binary file, load from a binary file, get the index of a basic generator. The description of these routines can be found in [Service Routines](#) section.
- Registration routines for basic pseudorandom generators and routines that obtain properties of the registered generators (see [Advanced Service Routines](#) section).

The last two categories are referred to as service routines.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Conventions

This document makes no specific differentiation between random, pseudorandom, and quasi-random numbers, nor between random, pseudorandom, and quasi-random number generators unless the context requires otherwise. For details, refer to the 'Random Numbers' section in [VS Notes](#) document provided at the Intel® MKL web page.

All generators of nonuniform distributions, both discrete and continuous, are built on the basis of the uniform distribution generators, called Basic Random Number Generators (BRNGs). The pseudorandom numbers with nonuniform distribution are obtained through an appropriate transformation of the uniformly distributed pseudorandom numbers. Such transformations are referred to as *generation methods*. For a given distribution, several generation methods can be used. See [VS Notes](#) for the description of methods available for each generator.

An RNG task determines environment in which random number generation is performed, in particular parameters of the BRNG and its internal state. Output of VS generators is a stream of random numbers that are used in Monte Carlo simulations. A *random stream descriptor* and a *random stream* are used as synonyms of an *RNG task* in the document unless the context requires otherwise.

The *random stream descriptor* specifies which BRNG should be used in a given transformation method. See the *Random Streams and RNGs in Parallel Computation* section of [VS Notes](#).

The term *computational node* means a logical or physical unit that can process data in parallel.

Mathematical Notation

The following notation is used throughout the text:

N	The set of natural numbers $N = \{1, 2, 3 \dots\}$.
Z	The set of integers $Z = \{\dots -3, -2, -1, 0, 1, 2, 3 \dots\}$.
R	The set of real numbers.
$\lfloor a \rfloor$	The floor of a (the largest integer less than or equal to a).
$\oplus$ or xor	Bitwise exclusive OR.
C_{α}^k or $\binom{\alpha}{k}$	Binomial coefficient or combination ($\alpha \in R, \alpha \geq 0; k \in \mathbb{N} \cup \{0\}$).
C_{α}^0	$C_{\alpha}^0 = 1$
	For $\alpha \geq k$ binomial coefficient is defined as

$$C_{\alpha}^k = \frac{\alpha(\alpha - 1) \dots (\alpha - k + 1)}{k!}$$

If $\alpha < k$, then

$$C_{\alpha}^k = 0$$

$\Phi(x)$

Cumulative Gaussian distribution function

$$\Phi(x) = \int_{-\infty}^x \frac{1}{\sqrt{2\pi}} \exp\left(-\frac{y^2}{2}\right) dy$$

defined over $-\infty < x < +\infty$.

$\Phi(-\infty) = 0$, $\Phi(+\infty) = 1$.

$\Gamma(\alpha)$

The complete gamma function

$$\Gamma(\alpha) = \int_0^{\infty} t^{\alpha-1} e^{-t} dt$$

where $\alpha > 0$.

$B(p, q)$

The complete beta function

$$B(p, q) = \int_0^1 t^{p-1} (1-t)^{q-1} dt$$

where $p > 0$ and $q > 0$.

$LCG(a, c, m)$

Linear Congruential Generator $x_{n+1} = (ax_n + c) \bmod m$, where a is called the *multiplier*, c is called the *increment*, and m is called the *modulus* of the generator.

$MCG(a, m)$

Multiplicative Congruential Generator $x_{n+1} = (ax_n) \bmod m$ is a special case of Linear Congruential Generator, where the increment c is taken to be 0.

$GFSR(p, q)$

Generalized Feedback Shift Register Generator

$$x_n = x_{n-p} \oplus x_{n-q}$$

Naming Conventions

The names of the routines, types, and constants in VS random number generators are case-sensitive and can contain lowercase and uppercase characters (`viRngUniform`).

The names of generator routines have the following structure:

```
v<type of result>Rng<distribution>
```

where

- *v* is the prefix of a VS vector function.
- *<type of result>* is either *s*, *d*, or *i* and specifies one of the following types:

<i>s</i>	float
<i>d</i>	double
<i>i</i>	int

Prefixes *s* and *d* apply to continuous distributions only, prefix *i* applies only to discrete case.

- *rng* indicates that the routine is a random generator.
- *<distribution>* specifies the type of statistical distribution.

Names of service routines follow the template below:

```
vsl<name>
```

where

- *vsl* is the prefix of a VS service function.
- *<name>* contains a short function name.

For a more detailed description of service routines, refer to [Service Routines](#) and [Advanced Service Routines](#) sections.

The prototype of each generator routine corresponding to a given probability distribution fits the following structure:

```
status = <function name>( method, stream, n, r, [<distribution parameters>] )
```

where

- *method* defines the method of generation. A detailed description of this parameter can be found in table "[Values of <method> in method parameter](#)". See the next page, where the structure of the *method* parameter name is explained.
- *stream* defines the descriptor of the random stream and must have a non-zero value. Random streams, descriptors, and their usage are discussed further in [Random Streams](#) and [Service Routines](#).
- *n* defines the number of random values to be generated. If *n* is less than or equal to zero, no values are generated. Furthermore, if *n* is negative, an error condition is set.
- *r* defines the destination array for the generated numbers. The dimension of the array must be large enough to store at least *n* random numbers.
- *status* defines the error status of a VS routine. See [Error Reporting](#) section for a detailed description of error status values.

Additional parameters included into *<distribution parameters>* field are individual for each generator routine and are described in detail in [Distribution Generators](#) section.

To invoke a distribution generator, use a call to the respective VS routine. For example, to obtain a vector *r*, composed of *n* independent and identically distributed random numbers with normal (Gaussian) distribution, that have the mean value *a* and standard deviation *sigma*, write the following:

```
status = vsRngGaussian( method, stream, n, r, a, sigma )
```

The name of a *method* parameter has the following structure:

```
VSL_RNG_METHOD_method<distribution>_<method>
```

```
VSL_RNG_METHOD_<distribution>_<method>_ACCURATE
```

where

- `<distribution>` is the probability distribution.
- `<method>` is the method name.

Type of the name structure for the `method` parameter corresponds to fast and accurate modes of random number generation (see "Distribution Generators" section and VS Notes for details).

Method names `VSL_RNG_METHOD_<distribution>_<method>`

and

`VSL_RNG_METHOD_<distribution>_<method>_ACCURATE`

should be used with

`v<precision>Rng<distribution>`

function only, where

- `<precision>` is
 - `s` for single precision continuous distribution
 - `d` for double precision continuous distribution
 - `i` for discrete distribution
- `<distribution>` is the probability distribution.

is the probability distribution. Table "Values of `<method>` in `method` parameter" provides specific predefined values of the `method` name. The third column contains names of the functions that use the given method.

Values of `<method>` in `method` parameter

Method	Short Description	Functions
STD	Standard method. Currently there is only one method for these functions.	Uniform (continuous), Uniform (discrete), UniformBits, UniformBits32, UniformBits64
BOXMULLER	BOXMULLER generates normally distributed random number x thru the pair of uniformly distributed numbers u_1 and u_2 according to the formula: $x = \sqrt{-2 \ln u_1} \sin 2\pi u_2$	Gaussian, GaussianMV
BOXMULLER2	BOXMULLER2 generates normally distributed random numbers x_1 and x_2 thru the pair of uniformly distributed numbers u_1 and u_2 according to the formulas: $x_1 = \sqrt{-2 \ln u_1} \sin 2\pi u_2$ $x_2 = \sqrt{-2 \ln u_1} \cos 2\pi u_2$	Gaussian, GaussianMV, Lognormal
ICDF	Inverse cumulative distribution function method.	Exponential, Laplace, Weibull, Cauchy, Rayleigh,

Method	Short Description	Functions
		Gumbel, Bernoulli, Geometric, Gaussian, GaussianMV, Lognormal
GNORM	For $\alpha > 1$, a gamma distributed random number is generated as a cube of properly scaled normal random number; for $0.6 \leq \alpha < 1$, a gamma distributed random number is generated using rejection from Weibull distribution; for $\alpha < 0.6$, a gamma distributed random number is obtained using transformation of exponential power distribution; for $\alpha = 1$, gamma distribution is reduced to exponential distribution.	Gamma
CJA	For $\min(p, q) > 1$, Cheng method is used; for $\min(p, q) < 1$, Johnk method is used, if $q + K \cdot p^2 + C \leq 0$ ($K = 0.852...$, $C = -0.956...$) otherwise, Atkinson switching algorithm is used; for $\max(p, q) < 1$, method of Johnk is used; for $\min(p, q) < 1$, $\max(p, q) > 1$, Atkinson switching algorithm is used (CJA stands for the first letters of Cheng, Johnk, Atkinson); for $p = 1$ or $q = 1$, inverse cumulative distribution function method is used; for $p = 1$ and $q = 1$, beta distribution is reduced to uniform distribution.	Beta
BTPE	Acceptance/rejection method for $n_{trial} \cdot \min(p, 1 - p) \geq 30$ with decomposition into 4 regions: – 2 parallelograms – triangle – left exponential tail – right exponential tail	Binomial
H2PE	Acceptance/rejection method for large mode of distribution with decomposition into 3 regions: – rectangular – left exponential tail – right exponential tail	Hypergeometric
PTPE	Acceptance/rejection method for $\lambda \geq 27$ with decomposition into 4 regions: – 2 parallelograms – triangle – left exponential tail – right exponential tail; otherwise, table lookup method is used.	Poisson
POISNORM	for $\lambda \geq 1$, method based on Poisson inverse CDF approximation by Gaussian inverse CDF; for $\lambda < 1$, table lookup method is used.	Poisson, PoissonV
NBAR	Acceptance/rejection method for ,	NegBinomial

Method	Short Description	Functions
	$\frac{(a-1) \cdot (1-p)}{p} \geq 100$	
	with decomposition into 5 regions: - rectangular - 2 trapezoid - left exponential tail - right exponential tail	

NOTE

In this document, routines are often referred to by their base name (`Gaussian`) when this does not lead to ambiguity. In the routine reference, the full name (`vsrnggaussian`, `vsRngGaussian`) is always used in prototypes and code examples.

Basic Generators

VS provides pseudorandom, quasi-random, and non-deterministic random number generators. This includes the following BRNGs, which differ in speed and other properties:

- the 31-bit multiplicative congruential pseudorandom number generator `MCG(1132489760, 231-1)` [[L'Ecuyer99](#)]
- the 32-bit generalized feedback shift register pseudorandom number generator `GFSR(250,103)` [[Kirkpatrick81](#)]
- the combined multiple recursive pseudorandom number generator `MRG32k3a` [[L'Ecuyer99a](#)]
- the 59-bit multiplicative congruential pseudorandom number generator `MCG(1313, 259)` from NAG Numerical Libraries [[NAG](#)]
- Wichmann-Hill pseudorandom number generator (a set of 273 basic generators) from NAG Numerical Libraries [[NAG](#)]
- Mersenne Twister pseudorandom number generator `MT19937` [[Matsumoto98](#)] with period length 2¹⁹⁹³⁷-1 of the produced sequence
- Set of 6024 Mersenne Twister pseudorandom number generators `MT2203` [[Matsumoto98](#)], [[Matsumoto00](#)]. Each of them generates a sequence of period length equal to 2²²⁰³-1. Parameters of the generators provide mutual independence of the corresponding sequences.
- SIMD-oriented Fast Mersenne Twister pseudorandom number generator `SFMT19937` [[Saito08](#)] with a period length equal to 2¹⁹⁹³⁷-1 of the produced sequence.
- Sobol quasi-random number generator [[Sobol76](#)], [[Bratley88](#)], which works in arbitrary dimension. For dimensions greater than 40 the user should supply initialization parameters (initial direction numbers and primitive polynomials or direction numbers) by using `vs1NewStreamEx` function. See additional details on interface for registration of the parameters in the library in [VS Notes](#).
- Niederreiter quasi-random number generator [[Bratley92](#)], which works in arbitrary dimension. For dimensions greater than 318 the user should supply initialization parameters (irreducible polynomials or direction numbers) by using `vs1NewStreamEx` function. See additional details on interface for registration of the parameters in the library in [VS Notes](#).
- Non-deterministic random number generator (RDRAND-based generators only) [[AVX](#)], [[IntelSWMan](#)].

NOTE

You can use a non-deterministic random number generator only if the underlying hardware supports it. For instructions on how to detect if an Intel CPU supports a non-deterministic random number generator see, for example, *Chapter 8: Post-32nm Processor Instructions* in [AVX] or *Chapter 4: RdRand Instruction Usage* in [BMT].

NOTE

The time required by some non-deterministic sources to generate a random number is not constant, so you might have to make multiple requests before the next random number is available. VS limits the number of retries for requests to the non-deterministic source to 10. You can redefine the maximum number of retries during the initialization of the non-deterministic random number generator with the `vslNewStreamEx` function.

For more details on the non-deterministic source implementation for Intel CPUs please refer to Section 7.3.17, Volume 1, *Random Number Generator Instruction* in [IntelSWMan] and Section 4.2.2, *RdRand Retry Loop* in [BMT].

- Philox4x32-10 counter-based pseudorandom number generator with a period of 2^{128} `PHILOX4X32X10` [Salmon11].
- ARS-5 counter-based pseudorandom number generator with a period of 2^{128} , which uses instructions from the AES-NI set `ARS5` [Salmon11].

See some testing results for the generators in [VS Notes](#) and comparative performance data at <https://software.intel.com/en-us/articles/intel-math-kernel-library-documentation>.

VS provides means of registration of such user-designed generators through the steps described in [Advanced Service Routines](#) section.

For some basic generators, VS provides two methods of creating independent random streams in multiprocessor computations, which are the leapfrog method and the block-splitting method. These sequence splitting methods are also useful in sequential Monte Carlo.

In addition, MT2203 pseudorandom number generator is a set of 6024 generators designed to create up to 6024 independent random sequences, which might be used in parallel Monte Carlo simulations. Another generator that has the same feature is Wichmann-Hill. It allows creating up to 273 independent random streams. The properties of the generators designed for parallel computations are discussed in detail in [Coddington94].

You may want to design and use your own basic generators. VS provides means of registration of such user-designed generators through the steps described in [Advanced Service Routines](#) section.

There is also an option to utilize externally generated random numbers in VS distribution generator routines. For this purpose VS provides three additional basic random number generators:

- for external random data packed in 32-bit integer array
- for external random data stored in double precision floating-point array; data is supposed to be uniformly distributed over (a,b) interval
- for external random data stored in single precision floating-point array; data is supposed to be uniformly distributed over (a,b) interval.

Such basic generators are called the abstract basic random number generators.

See [VS Notes](#) for a more detailed description of the generator properties.

Optimization Notice

Optimization Notice

optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

BRNG Parameter Definition

Predefined values for the *brng* input parameter are as follows:

Values of *brng* parameter

Value	Short Description
VSL_BRNG_MCG31	A 31-bit multiplicative congruential generator.
VSL_BRNG_R250	A generalized feedback shift register generator.
VSL_BRNG_MRG32K3A	A combined multiple recursive generator with two components of order 3.
VSL_BRNG_MCG59	A 59-bit multiplicative congruential generator.
VSL_BRNG_WH	A set of 273 Wichmann-Hill combined multiplicative congruential generators.
VSL_BRNG_MT19937	A Mersenne Twister pseudorandom number generator.
VSL_BRNG_MT2203	A set of 6024 Mersenne Twister pseudorandom number generators.
VSL_BRNG_SFMT19937	A SIMD-oriented Fast Mersenne Twister pseudorandom number generator.
VSL_BRNG_SOBOL	A 32-bit Gray code-based generator producing low-discrepancy sequences for dimensions $1 \leq s \leq 40$; user-defined dimensions are also available.
VSL_BRNG_NIEDERR	A 32-bit Gray code-based generator producing low-discrepancy sequences for dimensions $1 \leq s \leq 318$; user-defined dimensions are also available.
VSL_BRNG_IABSTRACT	An abstract random number generator for integer arrays.
VSL_BRNG_DABSTRACT	An abstract random number generator for double precision floating-point arrays.
VSL_BRNG_SABSTRACT	An abstract random number generator for single precision floating-point arrays.
VSL_BRNG_NONDETERM	A non-deterministic random number generator.
VSL_BRNG_PHILOX4X32X10	A Philox4x32-10 counter-based pseudorandom number generator.
VSL_BRNG_ARS5	An ARS-5 counter-based pseudorandom number generator that uses instructions from the AES-NI set.

See [VS Notes](#) for detailed description.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Random Streams

Random stream (or *stream*) is an abstract source of pseudo- and quasi-random sequences of uniform distribution. You can operate with stream state descriptors only. A stream state descriptor, which holds state descriptive information for a particular BRNG, is a necessary parameter in each routine of a distribution generator. Only the distribution generator routines operate with random streams directly. See [VS Notes](#) for details.

NOTE

Random streams associated with abstract basic random number generator are called the abstract random streams. See [VS Notes](#) for detailed description of abstract streams and their use.

You can create unlimited number of random streams by VS [Service Routines](#) like [NewStream](#) and utilize them in any distribution generator to get the sequence of numbers of given probability distribution. When they are no longer needed, the streams should be deleted calling service routine [DeleteStream](#).

VS provides service functions [SaveStreamF](#) and [LoadStreamF](#) to save random stream descriptive data to a binary file and to read this data from a binary file respectively. See [VS Notes](#) for detailed description.

Data Types

```
typedef(void*)VSLStreamStatePtr;
```

See [Advanced Service Routines](#) for the format of the stream state structure for user-designed generators.

Error Reporting

VS RNG routines return status codes of the performed operation to report errors to the calling program. The application should perform error-related actions and/or recover from the error. The status codes are of integer type and have the following format:

VSL_ERROR_<ERROR_NAME> - indicates VS errors common for all VS domains.

VSL_RNG_ERROR_<ERROR_NAME> - indicates VS RNG errors.

VS RNG errors are of negative values while warnings are of positive values. The status code of zero value indicates successful completion of the operation: VSL_ERROR_OK (or synonymic VSL_STATUS_OK).

Status Codes

Status Code	Description
Common VSL	
VSL_ERROR_OK, VSL_STATUS_OK	No error, execution is successful.
VSL_ERROR_BADARGS	Input argument value is not valid.

Status Code	Description
VSL_ERROR_CPU_NOT_SUPPORTED	CPU version is not supported.
VSL_ERROR_FEATURE_NOT_IMPLEMENTED	Feature invoked is not implemented.
VSL_ERROR_MEM_FAILURE	System cannot allocate memory.
VSL_ERROR_NULL_PTR	Input pointer argument is NULL.
VSL_ERROR_UNKNOWN	Unknown error.
VS RNG Specific	
VSL_RNG_ERROR_BAD_FILE_FORMAT	File format is unknown.
VSL_RNG_ERROR_BAD_MEM_FORMAT	Descriptive random stream format is unknown.
VSL_RNG_ERROR_BAD_NBITS	The value in <code>NBits</code> field is bad.
VSL_RNG_ERROR_BAD_NSEEDS	The value in <code>NSeeds</code> field is bad.
VSL_RNG_ERROR_BAD_STREAM	The random stream is invalid.
VSL_RNG_ERROR_BAD_STREAM_STATE_SIZE	The value in <code>StreamStateSize</code> field is bad.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> n_{\max}$.
VSL_RNG_ERROR_BAD_WORD_SIZE	The value in <code>WordSize</code> field is bad.
VSL_RNG_ERROR_BRNG_NOT_SUPPORTED	BRNG is not supported by the function.
VSL_RNG_ERROR_BRNG_TABLE_FULL	Registration cannot be completed due to lack of free entries in the table of registered BRNGs.
VSL_RNG_ERROR_BRNGS_INCOMPATIBLE	Two BRNGs are not compatible for the operation.
VSL_RNG_ERROR_FILE_CLOSE	Error in closing the file.
VSL_RNG_ERROR_FILE_OPEN	Error in opening the file.
VSL_RNG_ERROR_FILE_READ	Error in reading the file.
VSL_RNG_ERROR_FILE_WRITE	Error in writing the file.
VSL_RNG_ERROR_INVALID_ABSTRACT_STREAM	The abstract random stream is invalid.
VSL_RNG_ERROR_INVALID_BRNG_INDEX	BRNG index is not valid.
VSL_RNG_ERROR_LEAPFROG_UNSUPPORTED	BRNG does not support Leapfrog method.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns zero as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator is exceeded.
VSL_RNG_ERROR_SKIPAHEAD_UNSUPPORTED	BRNG does not support Skip-Ahead method.

Status Code	Description
VSL_RNG_ERROR_UNSUPPORTED_FILE_VER	File format version is not supported.
VSL_RNG_ERROR_NONDETERM_NOT_SUPPORTED	Non-deterministic random number generator is not supported on the CPU running the application.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number using non-deterministic random number generator exceeds threshold (see Section 7.2.1.12 <i>Non-deterministic</i> in [VS Notes] for more details)
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

VS RNG Usage Model

A typical algorithm for VS random number generators is as follows:

1. Create and initialize stream/streams. Functions `vslNewStream`, `vslNewStreamEx`, `vslCopyStream`, `vslCopyStreamState`, `vslLeapfrogStream`, `vslSkipAheadStream`.
2. Call one or more RNGs.
3. Process the output.
4. Delete the stream/streams. Function `vslDeleteStream`.

NOTE

You may reiterate steps 2-3. Random number streams may be generated for different threads.

The following example demonstrates generation of a random stream that is output of basic generator MT19937. The seed is equal to 777. The stream is used to generate 10,000 normally distributed random numbers in blocks of 1,000 random numbers with parameters $a = 5$ and $\sigma = 2$. Delete the streams after completing the generation. The purpose of the example is to calculate the sample mean for normal distribution with the given parameters.

Example of VS RNG Usage

```
#include <stdio.h>
#include "mkl_vsl.h"

int main()
{
    double r[1000]; /* buffer for random numbers */
    double s; /* average */
    VSLStreamStatePtr stream;
    int i, j;
```

```

/* Initializing */
s = 0.0;
vslNewStream( &stream, VSL_BRNG_MT19937, 777 );

/* Generating */
for ( i=0; i<10; i++ ) {
    vdRngGaussian( VSL_RNG_METHOD_GAUSSIAN_ICDF, stream, 1000, r, 5.0, 2.0 );
    for ( j=0; j<1000; j++ ) {
        s += r[j];
    }
}
s /= 10000.0;

/* Deleting the stream */
vslDeleteStream( &stream );

/* Printing results */
printf( "Sample mean of normal distribution = %f\n", s );

return 0;
}

```

Additionally, examples that demonstrate usage of VS random number generators are available in:

`${MKL}/examples/vslc/source`

Service Routines

Stream handling comprises routines for creating, deleting, or copying the streams and getting the index of a basic generator. A random stream can also be saved to and then read from a binary file. [Table "Service Routines"](#) lists all available service routines

Service Routines

Routine	Short Description
<code>vslNewStream</code>	Creates and initializes a random stream.
<code>vslNewStreamEx</code>	Creates and initializes a random stream for the generators with multiple initial conditions.
<code>vsliNewAbstractStream</code>	Creates and initializes an abstract random stream for integer arrays.
<code>vsldNewAbstractStream</code>	Creates and initializes an abstract random stream for double precision floating-point arrays.
<code>vslsNewAbstractStream</code>	Creates and initializes an abstract random stream for single precision floating-point arrays.
<code>vslDeleteStream</code>	Deletes previously created stream.
<code>vslCopyStream</code>	Copies a stream to another stream.
<code>vslCopyStreamState</code>	Creates a copy of a random stream state.
<code>vslSaveStreamF</code>	Writes a stream to a binary file.
<code>vslLoadStreamF</code>	Reads a stream from a binary file.
<code>vslSaveStreamM</code>	Writes a random stream descriptive data, including state, to a memory buffer.

Routine	Short Description
vslLoadStreamM	Creates a new stream and reads stream descriptive data, including state, from the memory buffer.
vslGetStreamSize	Computes size of memory necessary to hold the random stream.
vslLeapfrogStream	Initializes the stream by the leapfrog method to generate a subsequence of the original sequence.
vslSkipAheadStream	Initializes the stream by the skip-ahead method.
vslGetStreamStateBrng	Obtains the index of the basic generator responsible for the generation of a given random stream.
vslGetNumRegBrngs	Obtains the number of currently registered basic generators.

Most of the generator-based work comprises three basic steps:

1. Creating and initializing a stream ([vslNewStream](#), [vslNewStreamEx](#), [vslCopyStream](#), [vslCopyStreamState](#), [vslLeapfrogStream](#), [vslSkipAheadStream](#)).
2. Generating random numbers with given distribution, see [Distribution Generators](#).
3. Deleting the stream ([vslDeleteStream](#)).

Note that you can concurrently create multiple streams and obtain random data from one or several generators by using the stream state. You must use the [vslDeleteStream](#) function to delete all the streams afterwards.

vslNewStream

Creates and initializes a random stream.

Syntax

```
status = vslNewStream( &stream, brng, seed );
```

Include Files

- `mkl.h`

Input Parameters

Name	Type	Description
<i>brng</i>	<code>const MKL_INT</code>	Index of the basic generator to initialize the stream. See Table Values of <i>brng</i> parameter for specific value.
<i>seed</i>	<code>const MKL_UINT</code>	Initial condition of the stream. In the case of a quasi-random number generator seed parameter is used to set the dimension. If the dimension is greater than the dimension that <i>brng</i> can support or is less than 1, then the dimension is assumed to be equal to 1.

Output Parameters

Name	Type	Description
<i>stream</i>	<code>VSLStreamStatePtr*</code>	Stream state descriptor

Description

For a basic generator with number *brng*, this function creates a new stream and initializes it with a 32-bit seed. The seed is an initial value used to select a particular sequence generated by the basic generator *brng*. The function is also applicable for generators with multiple initial conditions. Use this function to create and initialize a new stream with a 32-bit seed only. If you need to provide multiple initial conditions such as several 32-bit or wider seeds, use the function [vslNewStreamEx](#). See [VS Notes](#) for a more detailed description of stream initialization for different basic generators.

NOTE

This function is not applicable for abstract basic random number generators. Please use [vslNewAbstractStream](#), [vslsNewAbstractStream](#) or [vsldNewAbstractStream](#) to utilize integer, single-precision or double-precision external random data respectively.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_RNG_ERROR_INVALID_BRNG_INDEX	BRNG index is invalid.
VSL_ERROR_MEM_FAILURE	System cannot allocate memory for <i>stream</i> .
VSL_RNG_ERROR_NONDETERMINISTIC_NOT_SUPPORTED	Non-deterministic random number generator is not supported.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

vslNewStreamEx

Creates and initializes a random stream for generators with multiple initial conditions.

Syntax

```
status = vslNewStreamEx( &stream, brng, n, params );
```

Include Files

- `mk1.h`

Input Parameters

Name	Type	Description
<i>brng</i>	const MKL_INT	Index of the basic generator to initialize the stream. See Table "Values of <i>brng</i> parameter" for specific value.
<i>n</i>	const MKL_INT	Number of initial conditions contained in <i>params</i>
<i>params</i>	const unsigned int	Array of initial conditions necessary for the basic generator <i>brng</i> to initialize the stream. In the case of a quasi-random number generator only the first element in <i>params</i> parameter is used to set the dimension. If the dimension is greater than the dimension that <i>brng</i> can support or is less than 1, then the dimension is assumed to be equal to 1.

Output Parameters

Name	Type	Description
<i>stream</i>	VSLStreamStatePtr*	Stream state descriptor

Description

The `vslNewStreamEx` function provides an advanced tool to set the initial conditions for a basic generator if its input arguments imply several initialization parameters. Initial values are used to select a particular sequence generated by the basic generator *brng*. Whenever possible, use `vslNewStream`, which is analogous to `vslNewStreamEx` except that it takes only one 32-bit initial condition. In particular, `vslNewStreamEx` may be used to initialize the state table in Generalized Feedback Shift Register Generators (GFSRs). A more detailed description of this issue can be found in [VS Notes](#).

This function is also used to pass user-defined initialization parameters of quasi-random number generators into the library. See [VS Notes](#) for the format for their passing and registration in VS.

NOTE

This function is not applicable for abstract basic random number generators. Please use `vsliNewAbstractStream`, `vslsNewAbstractStream` or `vsldNewAbstractStream` to utilize integer, single-precision or double-precision external random data respectively.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Return Values

<code>VSL_ERROR_OK</code> , <code>VSL_STATUS_OK</code>	Indicates no error, execution is successful.

VSL_RNG_ERROR_INVALID_BRNG_INDEX	BRNG index is invalid.
VSL_ERROR_MEM_FAILURE	System cannot allocate memory for <i>stream</i> .
VSL_RNG_ERROR_NONDETERMINISTIC_NOT_SUPPORTED	Non-deterministic random number generator is not supported.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

vsliNewAbstractStream

Creates and initializes an abstract random stream for integer arrays.

Syntax

```
status = vsliNewAbstractStream( &stream, n, ibuf, icallback );
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>n</i>	const MKL_INT	Size of the array <i>ibuf</i>
<i>ibuf</i>	const unsigned int	Array of <i>n</i> 32-bit integers
<i>icallback</i>		Pointer to the callback function used for <i>ibuf</i> update

NOTE

Format of the callback function:

```
int iUpdateFunc( VSLStreamStatePtrstream, int* n, unsigned int ibuf[], int* nmin, int* nmax, int* idx );
```

The callback function returns the number of elements in the array actually updated by the function. [Table icallback Callback Function Parameters](#) gives the description of the callback function parameters.

icallback Callback Function Parameters

Parameters	Short Description
<i>stream</i>	Abstract random stream descriptor
<i>n</i>	Size of <i>ibuf</i>
<i>ibuf</i>	Array of random numbers associated with the stream <i>stream</i>
<i>nmin</i>	Minimal quantity of numbers to update
<i>nmax</i>	Maximal quantity of numbers that can be updated
<i>idx</i>	Position in cyclic buffer <i>ibuf</i> to start update $0 \leq idx < n$.

Output Parameters

Name	Type	Description
<i>stream</i>	VSLStreamStatePtr*	Descriptor of the stream state structure

Description

The `vsliNewAbstractStream` function creates a new abstract stream and associates it with an integer array *ibuf* and your callback function *icallback* that is intended for updating of *ibuf* content.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_BADARGS	Parameter <i>n</i> is not positive.
VSL_ERROR_MEM_FAILURE	System cannot allocate memory for <i>stream</i> .
VSL_ERROR_NULL_PTR	Either buffer or callback function parameter is a NULL pointer.

vsldNewAbstractStream

Creates and initializes an abstract random stream for double precision floating-point arrays.

Syntax

```
status = vsldNewAbstractStream( &stream, n, dbuf, a, b, dcallback );
```

Include Files

- `mk1.h`

Input Parameters

Name	Type	Description
<i>n</i>	const MKL_INT	Size of the array <i>dbuf</i>
<i>dbuf</i>	const double	Array of <i>n</i> double precision floating-point random numbers with uniform distribution over interval (a,b)
<i>a</i>	const double	Left boundary a
<i>b</i>	const double	Right boundary b
<i>dcallback</i>	See <i>Note</i> below	Pointer to the callback function used for update of the array <i>dbuf</i>

Output Parameters

Name	Type	Description
<i>stream</i>	VSLStreamStatePtr*	Descriptor of the stream state structure

NOTE

Format of the callback function:

```
int dUpdateFunc( VSLStreamStatePtr stream, int* n, double dbuf[], int* nmin, int* nmax, int*
idx );
```

The callback function returns the number of elements in the array actually updated by the function. [Table dcallback Callback Function Parameters](#) gives the description of the callback function parameters.

dcallback Callback Function Parameters

Parameters	Short Description
<i>stream</i>	Abstract random stream descriptor
<i>n</i>	Size of <i>dbuf</i>
<i>dbuf</i>	Array of random numbers associated with the stream <i>stream</i>
<i>nmin</i>	Minimal quantity of numbers to update
<i>nmax</i>	Maximal quantity of numbers that can be updated
<i>idx</i>	Position in cyclic buffer <i>dbuf</i> to start update $0 \leq idx < n$.

Description

The `vsldNewAbstractStream` function creates a new abstract stream for double precision floating-point arrays with random numbers of the uniform distribution over interval (a,b). The function associates the stream with a double precision array *dbuf* and your callback function *dcallback* that is intended for updating of *dbuf* content.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_BADARGS	Parameter <i>n</i> is not positive.
VSL_ERROR_MEM_FAILURE	System cannot allocate memory for <i>stream</i> .
VSL_ERROR_NULL_PTR	Either buffer or callback function parameter is a NULL pointer.

vsldNewAbstractStream

Creates and initializes an abstract random stream for single precision floating-point arrays.

Syntax

```
status = vsldNewAbstractStream( &stream, n, sbuf, a, b, scallback );
```

Include Files

- `mk1.h`

Input Parameters

Name	Type	Description
<i>n</i>	const MKL_INT	Size of the array <i>sbuf</i>
<i>sbuf</i>	const float	Array of <i>n</i> single precision floating-point random numbers with uniform distribution over interval (a,b)
<i>a</i>	const float	Left boundary a
<i>b</i>	const float	Right boundary b
<i>scallback</i>	See <i>Note</i> below	Pointer to the callback function used for update of the array <i>sbuf</i>

Output Parameters

Name	Type	Description
<i>stream</i>	VSLStreamStatePtr*	Descriptor of the stream state structure

NOTE

Format of the callback function in C:

```
int sUpdateFunc( VSLStreamStatePtr stream, int* n, float sbuf[], int* nmin, int* nmax, int* idx );
```

The callback function returns the number of elements in the array actually updated by the function. [Table *scallback* Callback Function Parameters](#) gives the description of the callback function parameters.

scallback Callback Function Parameters

Parameters	Short Description
<i>stream</i>	Abstract random stream descriptor
<i>n</i>	Size of <i>sbuf</i>
<i>sbuf</i>	Array of random numbers associated with the stream <i>stream</i>
<i>nmin</i>	Minimal quantity of numbers to update
<i>nmax</i>	Maximal quantity of numbers that can be updated
<i>idx</i>	Position in cyclic buffer <i>sbuf</i> to start update $0 \leq idx < n$.

Description

The `vslsNewAbstractStream` function creates a new abstract stream for single precision floating-point arrays with random numbers of the uniform distribution over interval (a,b). The function associates the stream with a single precision array *sbuf* and your callback function *scallback* that is intended for updating of *sbuf* content.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_BADARGS	Parameter <i>n</i> is not positive.

VSL_ERROR_MEM_FAILURE	System cannot allocate memory for <i>stream</i> .
VSL_ERROR_NULL_PTR	Either buffer or callback function parameter is a NULL pointer.

vslDeleteStream

Deletes a random stream.

Syntax

```
status = vslDeleteStream( &stream );
```

Include Files

- mkl.h

Input/Output Parameters

Name	Type	Description
<i>stream</i>	VSLStreamStatePtr*	Stream state descriptor. Must have non-zero value. After the stream is successfully deleted, the pointer is set to NULL.

Description

The function deletes the random stream created by one of the initialization functions.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> parameter is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.

vslCopyStream

Creates a copy of a random stream.

Syntax

```
status = vslCopyStream( &newstream, srcstream );
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>srcstream</i>	const VSLStreamStatePtr	Pointer to the stream state structure to be copied

Output Parameters

Name	Type	Description
<i>newstream</i>	VSLStreamStatePtr*	Copied random stream descriptor

Description

The function creates an exact copy of *srcstream* and stores its descriptor to *newstream*.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>srcstream</i> parameter is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>srcstream</i> is not a valid random stream.
VSL_ERROR_MEM_FAILURE	System cannot allocate memory for <i>newstream</i> .

vslCopyStreamState

Creates a copy of a random stream state.

Syntax

```
status = vslCopyStreamState( deststream, srcstream );
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>srcstream</i>	const VSLStreamStatePtr	Pointer to the stream state structure, from which the state structure is copied

Output Parameters

Name	Type	Description
<i>deststream</i>	VSLStreamStatePtr	Pointer to the stream state structure where the stream state is copied

Description

The `vslCopyStreamState` function copies a stream state from *srcstream* to the existing *deststream* stream. Both the streams should be generated by the same basic generator. An error message is generated when the index of the BRNG that produced *deststream* stream differs from the index of the BRNG that generated *srcstream* stream.

Unlike `vslCopyStream` function, which creates a new stream and copies both the stream state and other data from *srcstream*, the function `vslCopyStreamState` copies only *srcstream* stream state data to the generated *deststream* stream.

Return Values

<code>VSL_ERROR_OK, VSL_STATUS_OK</code>	Indicates no error, execution is successful.
<code>VSL_ERROR_NULL_PTR</code>	Either <i>srcstream</i> or <i>deststream</i> is a <code>NULL</code> pointer.
<code>VSL_RNG_ERROR_BAD_STREAM</code>	Either <i>srcstream</i> or <i>deststream</i> is not a valid random stream.
<code>VSL_RNG_ERROR_BRNGS_INCOMPATIBLE</code>	BRNG associated with <i>srcstream</i> is not compatible with BRNG associated with <i>deststream</i> .

vslSaveStreamF

Writes random stream descriptive data, including stream state, to binary file.

Syntax

```
errstatus = vslSaveStreamF( stream, fname );
```

Include Files

- `mkl.h`

Input Parameters

Name	Type	Description
<i>stream</i>	<code>const VSLStreamStatePtr</code>	Random stream to be written to the file
<i>fname</i>	<code>const char*</code>	File name specified as a null-terminated string

Output Parameters

Name	Type	Description
<i>errstatus</i>	<code>int</code>	Error status of the operation

Description

The `vslSaveStreamF` function writes the random stream descriptive data, including the stream state, to the binary file. Random stream descriptive data is saved to the binary file with the name *fname*. The random stream *stream* must be a valid stream created by `vslNewStream`-like or `vslCopyStream`-like service routines. If the stream cannot be saved to the file, *errstatus* has a non-zero value. The random stream can be read from the binary file using the `vslLoadStreamF` function.

Return Values

<code>VSL_ERROR_OK, VSL_STATUS_OK</code>	Indicates no error, execution is successful.
<code>VSL_ERROR_NULL_PTR</code>	Either <i>fname</i> or <i>stream</i> is a <code>NULL</code> pointer.
<code>VSL_RNG_ERROR_BAD_STREAM</code>	<i>stream</i> is not a valid random stream.
<code>VSL_RNG_ERROR_FILE_OPEN</code>	Indicates an error in opening the file.
<code>VSL_RNG_ERROR_FILE_WRITE</code>	Indicates an error in writing the file.

VSL_RNG_ERROR_FILE_CLOSE	Indicates an error in closing the file.
VSL_ERROR_MEM_FAILURE	System cannot allocate memory for internal needs.

vslLoadStreamF

Creates new stream and reads stream descriptive data, including stream state, from binary file.

Syntax

```
errstatus = vslLoadStreamF( &stream, fname );
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>fname</i>	const char*	File name specified as a null-terminated string

Output Parameters

Name	Type	Description
<i>stream</i>	VSLStreamStatePtr*	Pointer to a new random stream
<i>errstatus</i>	int	Error status of the operation

Description

The `vslLoadStreamF` function creates a new stream and reads stream descriptive data, including the stream state, from the binary file. A new random stream is created using the stream descriptive data from the binary file with the name *fname*. If the stream cannot be read (for example, an I/O error occurs or the file format is invalid), *errstatus* has a non-zero value. To save random stream to the file, use `vslSaveStreamF` function.

CAUTION

Calling `vslLoadStreamF` with a previously initialized *stream* pointer can have unintended consequences such as a memory leak. To initialize a stream which has been in use until calling `vslLoadStreamF`, you should call the `vslDeleteStream` function first to deallocate the resources.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>fname</i> is a NULL pointer.
VSL_RNG_ERROR_FILE_OPEN	Indicates an error in opening the file.
VSL_RNG_ERROR_FILE_WRITE	Indicates an error in writing the file.
VSL_RNG_ERROR_FILE_CLOSE	Indicates an error in closing the file.
VSL_ERROR_MEM_FAILURE	System cannot allocate memory for internal needs.
VSL_RNG_ERROR_BAD_FILE_FORMAT	Unknown file format.
VSL_RNG_ERROR_UNSUPPORTED_FILE_VER	File format version is unsupported.
VSL_RNG_ERROR_NONDETERMINISTIC_NOT_SUPPORTED	Non-deterministic random number generator is not supported.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

vslSaveStreamM

Writes random stream descriptive data, including stream state, to a memory buffer.

Syntax

```
errstatus = vslSaveStreamM( stream, memptr );
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>stream</i>	const VSLStreamStatePtr	Random stream to be written to the memory
<i>memptr</i>	char*	Memory buffer to save random stream descriptive data to

Output Parameters

Name	Type	Description
<i>errstatus</i>	int	Error status of the operation

Description

The `vslSaveStreamM` function writes the random stream descriptive data, including the stream state, to the memory at *memptr*. Random stream *stream* must be a valid stream created by `vslNewStream`-like or `vslCopyStream`-like service routines. The *memptr* parameter must be a valid pointer to the memory of size sufficient to hold the random stream *stream*. Use the service routine `vslGetStreamSize` to determine this amount of memory.

If the stream cannot be saved to the memory, *errstatus* has a non-zero value. The random stream can be read from the memory pointed by *memptr* using the [vslLoadStreamM](#) function.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	Either <i>memptr</i> or <i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is a NULL pointer.

vslLoadStreamM

Creates a new stream and reads stream descriptive data, including stream state, from the memory buffer.

Syntax

```
errstatus = vslLoadStreamM( &stream, memptr );
```

Include Files

- `mkl.h`

Input Parameters

Name	Type	Description
<i>memptr</i>	<code>const char*</code>	Memory buffer to load random stream descriptive data from

Output Parameters

Name	Type	Description
<i>stream</i>	<code>VSLStreamStatePtr*</code>	Pointer to a new random stream
<i>errstatus</i>	<code>int</code>	Error status of the operation

Description

The [vslLoadStreamM](#) function creates a new stream and reads stream descriptive data, including the stream state, from the memory buffer. A new random stream is created using the stream descriptive data from the memory pointer by *memptr*. If the stream cannot be read (for example, *memptr* is invalid), *errstatus* has a non-zero value. To save random stream to the memory, use [vslSaveStreamM](#) function. Use the service routine [vslGetStreamSize](#) to determine the amount of memory sufficient to hold the random stream.

CAUTION

Calling [LoadStreamM](#) with a previously initialized *stream* pointer can have unintended consequences such as a memory leak. To initialize a stream which has been in use until calling [vslLoadStreamM](#), you should call the [vslDeleteStream](#) function first to deallocate the resources.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or

Optimization Notice

effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Notice revision #20110804

Return Values

<code>VSL_ERROR_OK, VSL_STATUS_OK</code>	Indicates no error, execution is successful.
<code>VSL_ERROR_NULL_PTR</code>	<i>memptr</i> is a <code>NULL</code> pointer.
<code>VSL_ERROR_MEM_FAILURE</code>	System cannot allocate memory for internal needs.
<code>VSL_RNG_ERROR_BAD_MEM_FORMAT</code>	Descriptive random stream format is unknown.
<code>VSL_RNG_ERROR_NONDETERMINISTIC_NOT_SUPPORTED</code>	Non-deterministic random number generator is not supported.
<code>VSL_RNG_ERROR_ARS5_NOT_SUPPORTED</code>	ARS-5 random number generator is not supported on the CPU running the application.

vslGetStreamSize

Computes size of memory necessary to hold the random stream.

Syntax

```
memsiz = vslGetStreamSize( stream );
```

Include Files

- `mkl.h`

Input Parameters

Name	Type	Description
<i>stream</i>	<code>const VSLStreamStatePtr</code>	Random stream

Output Parameters

Name	Type	Description
<i>memsiz</i>	<code>int</code>	Amount of memory in bytes necessary to hold descriptive data of random stream <i>stream</i>

Description

The `vslGetStreamSize` function returns the size of memory in bytes which is necessary to hold the given random stream. Use the output of the function to allocate the buffer to which you will save the random stream by means of the `vslSaveStreamM` function.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is a NULL pointer.

vslLeapfrogStream

Initializes a stream using the leapfrog method.

Syntax

```
status = vslLeapfrogStream( stream, k, nstreams );
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>stream</i>	VSLStreamStatePtr	Pointer to the stream state structure to which leapfrog method is applied
<i>k</i>	const MKL_INT	Index of the computational node, or stream number
<i>nstreams</i>	const MKL_INT	Largest number of computational nodes, or stride

Description

The `vslLeapfrogStream` function generates random numbers in a random stream with non-unit stride. This feature is particularly useful in distributing random numbers from the original stream across the *nstreams* buffers without generating the original random sequence with subsequent manual distribution.

One of the important applications of the leapfrog method is splitting the original sequence into non-overlapping subsequences across *nstreams* computational nodes. The function initializes the original random stream (see [Figure "Leapfrog Method"](#)) to generate random numbers for the computational node *k*, $0 \leq k < nstreams$, where *nstreams* is the largest number of computational nodes used.

Leapfrog Method

The leapfrog method is supported only for those basic generators that allow splitting elements by the leapfrog method, which is more efficient than simply generating them by a generator with subsequent manual distribution across computational nodes. See [VS Notes](#) for details.

For quasi-random basic generators, the leapfrog method allows generating individual components of quasi-random vectors instead of whole quasi-random vectors. In this case *nstreams* parameter should be equal to the dimension of the quasi-random vector while *k* parameter should be the index of a component to be generated ($0 \leq k < nstreams$). Other parameters values are not allowed.

The following code illustrates the initialization of three independent streams using the leapfrog method:

Code for Leapfrog Method

```
...
VSLStreamStatePtr stream1;
VSLStreamStatePtr stream2;
VSLStreamStatePtr stream3;

/* Creating 3 identical streams */
status = vslNewStream(&stream1, VSL_BRNG_MCG31, 174);
status = vslCopyStream(&stream2, stream1);
status = vslCopyStream(&stream3, stream1);

/* Leapfrogging the streams
*/
status = vslLeapfrogStream(stream1, 0, 3);
status = vslLeapfrogStream(stream2, 1, 3);
status = vslLeapfrogStream(stream3, 2, 3);

/* Generating random numbers
*/
...
/* Deleting the streams
*/
status = vslDeleteStream(&stream1);
status = vslDeleteStream(&stream2);
status = vslDeleteStream(&stream3);
...
```

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_LEAPFROG_UNSUPPORTED	BRNG does not support Leapfrog method.

vslSkipAheadStream

Initializes a stream using the block-splitting method.

Syntax

```
status = vslSkipAheadStream( stream, nskip);
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>stream</i>	VSLStreamStatePtr	Pointer to the stream state structure to which block-splitting method is applied
<i>nskip</i>	const long long int	Number of skipped elements

Description

The `vslSkipAheadStream` function skips a given number of elements in a random stream. This feature is particularly useful in distributing random numbers from original random stream across different computational nodes. If the largest number of random numbers used by a computational node is *nskip*, then the original random sequence may be split by `vslSkipAheadStream` into non-overlapping blocks of *nskip* size so that each block corresponds to the respective computational node. The number of computational nodes is unlimited. This method is known as the block-splitting method or as the skip-ahead method. (see [Figure "Block-Splitting Method"](#)).

Block-Splitting Method

The skip-ahead method is supported only for those basic generators that allow skipping elements by the skip-ahead method, which is more efficient than simply generating them by generator with subsequent manual skipping. See [VS Notes](#) for details.

Please note that for quasi-random basic generators the skip-ahead method works with components of quasi-random vectors rather than with whole quasi-random vectors. Therefore, to skip *NS* quasi-random vectors, set the *nskip* parameter equal to the *NS*DIMEN*, where *DIMEN* is the dimension of the quasi-random vector. If this operation results in exceeding the period of the quasi-random number generator, which is $2^{32}-1$, the library returns the `VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED` error code.

The following code illustrates how to initialize three independent streams using the `vslSkipAheadStream` function:

Code for Block-Splitting Method

```
VSLStreamStatePtr stream1;
VSLStreamStatePtr stream2;
VSLStreamStatePtr stream3;
```

```

/* Creating the 1st stream
*/
status = vslNewStream(&stream1, VSL_BRNG_MCG31, 174);

/* Skipping ahead by 7 elements the 2nd stream */
status = vslCopyStream(&stream2, stream1);
status = vslSkipAheadStream(stream2, 7);

/* Skipping ahead by 7 elements the 3rd stream */
status = vslCopyStream(&stream3, stream2);
status = vslSkipAheadStream(stream3, 7);

/* Generating random numbers
*/
...
/* Deleting the streams
*/
status = vslDeleteStream(&stream1);
status = vslDeleteStream(&stream2);
status = vslDeleteStream(&stream3);
...

```

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_SKIPAHEAD_UNSUPPORTED	BRNG does not support the Skip-Ahead method.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the quasi-random number generator is exceeded.

vslGetStreamStateBrng

Returns index of a basic generator used for generation of a given random stream.

Syntax

```
brng = vslGetStreamStateBrng( stream );
```

Include Files

- `mk1.h`

Input Parameters

Name	Type	Description
<i>stream</i>	<code>const VSLStreamStatePtr</code>	Pointer to the stream state structure

Output Parameters

Name	Type	Description
<i>brng</i>	int	Index of the basic generator assigned for the generation of <i>stream</i> ; negative in case of an error

Description

The `vslGetStreamStateBrng` function retrieves the index of a basic generator used for generation of a given random stream.

Return Values

VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.

vslGetNumRegBrngs

Obtains the number of currently registered basic generators.

Syntax

```
nregbrngs = vslGetNumRegBrngs( void );
```

Include Files

- `mk1.h`

Output Parameters

Name	Type	Description
<i>nregbrngs</i>	int	Number of basic generators registered at the moment of the function call

Description

The `vslGetNumRegBrngs` function obtains the number of currently registered basic generators. Whenever user registers a user-designed basic generator, the number of registered basic generators is incremented. The maximum number of basic generators that can be registered is determined by the `VSL_MAX_REG_BRNGS` parameter.

Distribution Generators

Intel MKL VS routines are used to generate random numbers with different types of distribution. Each function group is introduced below by the type of underlying distribution and contains a short description of its functionality, as well as specifications of the call sequence and the explanation of input and output parameters. [Table "Continuous Distribution Generators"](#) and [Table "Discrete Distribution Generators"](#) list the random number generator routines with data types and output distributions, and sets correspondence between data types of the generator routines and the basic random number generators.

Continuous Distribution Generators

Type of Distribution	Data Types	BRNG Data Type	Description
<code>vRngUniform</code>	s, d	s, d	Uniform continuous distribution on the interval $[a,b)$

Type of Distribution	Data Types	BRNG Data Type	Description
<code>vRngGaussian</code>	s, d	s, d	Normal (Gaussian) distribution
<code>vRngGaussianMV</code>	s, d	s, d	Multivariate normal (Gaussian) distribution
<code>vRngExponential</code>	s, d	s, d	Exponential distribution
<code>vRngLaplace</code>	s, d	s, d	Laplace distribution (double exponential distribution)
<code>vRngWeibull</code>	s, d	s, d	Weibull distribution
<code>vRngCauchy</code>	s, d	s, d	Cauchy distribution
<code>vRngRayleigh</code>	s, d	s, d	Rayleigh distribution
<code>vRngLognormal</code>	s, d	s, d	Lognormal distribution
<code>vRngGumbel</code>	s, d	s, d	Gumbel (extreme value) distribution
<code>vRngGamma</code>	s, d	s, d	Gamma distribution
<code>vRngBeta</code>	s, d	s, d	Beta distribution

Discrete Distribution Generators

Type of Distribution	Data Types	BRNG Data Type	Description
<code>vRngUniform</code>	i	d	Uniform discrete distribution on the interval $[a, b]$
<code>vRngUniformBits</code>	i	i	Underlying BRNG integer recurrence
<code>vRngUniformBits 32</code>	i	i	Uniformly distributed bits in 32-bit chunks
<code>vRngUniformBits 64</code>	i	i	Uniformly distributed bits in 64-bit chunks
<code>vRngBernoulli</code>	i	s	Bernoulli distribution
<code>vRngGeometric</code>	i	s	Geometric distribution
<code>vRngBinomial</code>	i	d	Binomial distribution
<code>vRngHypergeometric</code>	i	d	Hypergeometric distribution
<code>vRngPoisson</code>	i	s (for <code>VSL_RNG_METHOD_POISSON_POISNORM</code>) s (for distribution parameter $\lambda \geq 27$) and d (for $\lambda < 27$) (for <code>VSL_RNG_METHOD_POISSON_PTPE</code>)	Poisson distribution
<code>vRngPoissonV</code>	i	s	Poisson distribution with varying mean
<code>vRngNegBinomial</code>	i	d	Negative binomial distribution, or Pascal distribution

Modes of random number generation

The library provides two modes of random number generation, accurate and fast. Accurate generation mode is intended for the applications that are highly demanding to accuracy of calculations. When used in this mode, the generators produce random numbers lying completely within definitional domain for all values of the distribution parameters. For example, random numbers obtained from the generator of continuous distribution that is uniform on interval $[a,b]$ belong to this interval irrespective of what a and b values may be. Fast mode provides high performance of generation and also guarantees that generated random numbers belong to the definitional domain except for some specific values of distribution parameters. The generation mode is set by specifying relevant value of the method parameter in generator routines. List of distributions that support accurate mode of generation is given in the table below.

Distribution Generators Supporting Accurate Mode

Type of Distribution	Data Types
<code>vRngUniform</code>	s, d
<code>vRngExponential</code>	s, d
<code>vRngWeibull</code>	s, d
<code>vRngRayleigh</code>	s, d
<code>vRngLognormal</code>	s, d
<code>vRngGamma</code>	s, d
<code>vRngBeta</code>	s, d

See additional details about accurate and fast mode of random number generation in [VS Notes](#).

New method names

The current version of Intel MKL has a modified structure of VS RNG method names. (See [RNG Naming Conventions](#) for details.) The old names are kept for backward compatibility. The set correspondence between the new and legacy method names for VS random number generators.

Method Names for Continuous Distribution Generators

RNG	Legacy Method Name	New Method Name
<code>vRngUniform</code>	VSL_METHOD_SUNIFORM_STD, VSL_METHOD_DUNIFORM_STD, VSL_METHOD_SUNIFORM_STD_ACCURATE, VSL_METHOD_DUNIFORM_STD_ACCURATE	VSL_RNG_METHOD_UNIFORM_STD, VSL_RNG_METHOD_UNIFORM_STD_ACCURATE
<code>vRngGaussia n</code>	VSL_METHOD_SGAUSSIAN_BOXMULLER, VSL_METHOD_SGAUSSIAN_BOXMULLER2, VSL_METHOD_SGAUSSIAN_ICDF, VSL_METHOD_DGAUSSIAN_BOXMULLER, VSL_METHOD_DGAUSSIAN_BOXMULLER2, VSL_METHOD_DGAUSSIAN_ICDF	VSL_RNG_METHOD_GAUSSIAN_BOXMULLER, VSL_RNG_METHOD_GAUSSIAN_BOXMULLER2, VSL_RNG_METHOD_GAUSSIAN_ICDF
<code>vRngGaussia nMV</code>	VSL_METHOD_SGAUSSIANMV_BOXMULLER, VSL_METHOD_SGAUSSIANMV_BOXMULLER2, VSL_METHOD_SGAUSSIANMV_ICDF, VSL_METHOD_DGAUSSIANMV_BOXMULLER, VSL_METHOD_DGAUSSIANMV_BOXMULLER2, VSL_METHOD_DGAUSSIANMV_ICDF	VSL_RNG_METHOD_GAUSSIANMV_BOXMULLER , VSL_RNG_METHOD_GAUSSIANMV_BOXMULLER 2, VSL_RNG_METHOD_GAUSSIANMV_ICDF

RNG	Legacy Method Name	New Method Name

Continuous Distributions

This section describes routines for generating random numbers with continuous distribution.

vRngUniform

Generates random numbers with uniform distribution.

Syntax

```
status = vsRngUniform( method, stream, n, r, a, b );
```

```
status = vdRngUniform( method, stream, n, r, a, b );
```

Include Files

- `mk1.h`

Input Parameters

Name	Type	Description
<code>method</code>	<code>const MKL_INT</code>	Generation method; the specific values are as follows: <code>VSL_RNG_METHOD_UNIFORM_STD</code> <code>VSL_RNG_METHOD_UNIFORM_STD_ACCURATE</code> Standard method.
<code>stream</code>	<code>VSLStreamStatePtr</code>	Pointer to the stream state structure
<code>n</code>	<code>const MKL_INT</code>	Number of random values to be generated
<code>a</code>	<code>const float</code> for <code>vsRngUniform</code> <code>const double</code> for <code>vdRngUniform</code>	Left bound a
<code>b</code>	<code>const float</code> for <code>vsRngUniform</code>	Right bound b

Name	Type	Description
	<code>const double for vdRngUniform</code>	

Output Parameters

Name	Type	Description
<i>r</i>	<code>float* for vsRngUniform double* for vdRngUniform</code>	Vector of <i>n</i> random numbers uniformly distributed over the interval $[a, b)$

Description

The `vdRngUniform` function generates random numbers uniformly distributed over the interval $[a, b)$, where a, b are the left and right bounds of the interval, respectively, and $a, b \in \mathbb{R}$; $a < b$.

The probability density function is given by:

$$f(x) = \frac{1}{b-a} \quad \text{for } a \leq x < b$$

The cumulative distribution function is as follows:

$$F(x) = \frac{x-a}{b-a} \quad \text{for } a \leq x < b$$

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Return Values

<code>VSL_ERROR_OK, VSL_STATUS_OK</code>	Indicates no error, execution is successful.
<code>VSL_ERROR_NULL_PTR</code>	<i>stream</i> is a NULL pointer.

VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> nmax$.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

vRngGaussian

Generates normally distributed random numbers.

Syntax

```
status = vsRngGaussian( method, stream, n, r, a, sigma );
status = vdRngGaussian( method, stream, n, r, a, sigma );
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>method</i>	const MKL_INT	Generation method. The specific values are as follows: VSL_RNG_METHOD_GAUSSIAN_BOXMULLER VSL_RNG_METHOD_GAUSSIAN_BOXMULLER2 VSL_RNG_METHOD_GAUSSIAN_ICDF See brief description of the methods BOXMULLER, BOXMULLER2, and ICDF in Table "Values of <method> in method parameter"
<i>stream</i>	VSLStreamStatePtr	Pointer to the stream state structure
<i>n</i>	const MKL_INT	Number of random values to be generated
<i>a</i>	const float for vsRngGaussian const double for vdRngGaussian	Mean value μ .
<i>sigma</i>	const float for vsRngGaussian	Standard deviation σ .

Name	Type	Description

	const double for vdRngGaussian	

Output Parameters

Name	Type	Description

r	float* for vsRngGaussian double* for vdRngGaussian	Vector of n normally distributed random numbers

Description

The `vdRngGaussian` function generates random numbers with normal (Gaussian) distribution with mean value a and standard deviation σ , where

$a, \sigma \in \mathbb{R}$; $\sigma > 0$.

The probability density function is given by:

$$f_{a,\sigma}(x) = \frac{1}{\sigma\sqrt{2\pi}} \exp\left(-\frac{(x-a)^2}{2\sigma^2}\right), \quad -\infty < x < +\infty.$$

The cumulative distribution function is as follows:

$$F_{a,\sigma}(x) = \int_{-\infty}^x \frac{1}{\sigma\sqrt{2\pi}} \exp\left(-\frac{(y-a)^2}{2\sigma^2}\right) dy, \quad -\infty < x < +\infty.$$

The cumulative distribution function $F_{a,\sigma}(x)$ can be expressed in terms of standard normal distribution $\Phi(x)$ as

$$F_{a,\sigma}(x) = \Phi((x-a)/\sigma)$$

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Return Values

VSL_ERROR_OK, VSL_STATUS_OK

Indicates no error, execution is successful.

VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> nmax$.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

vRngGaussianMV

Generates random numbers from multivariate normal distribution.

Syntax

```
status = vsRngGaussianMV( method, stream, n, r, dimen, mstorage, a, t );
status = vdRngGaussianMV( method, stream, n, r, dimen, mstorage, a, t );
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>method</i>	const MKL_INT	Generation method. The specific values are as follows: VSL_RNG_METHOD_GAUSSIANMV_BOXMULLER VSL_RNG_METHOD_GAUSSIANMV_BOXMULLER2 VSL_RNG_METHOD_GAUSSIANMV_ICDF See brief description of the methods BOXMULLER, BOXMULLER2, and ICDF in Table "Values of <method> in method parameter"
<i>stream</i>	VSLStreamStatePtr	Pointer to the stream state structure
<i>n</i>	const MKL_INT	Number of d -dimensional vectors to be generated
<i>dimen</i>	const MKL_INT	Dimension d ($d \geq 1$) of output random vectors
<i>mstorage</i>	const MKL_INT	Matrix storage scheme for lower triangular matrix T . The routine supports three matrix storage schemes:

Name	Type	Description
		- VSL_MATRIX_STORAGE_FULL— all $d \times d$ elements of the matrix T are passed, however, only the lower triangle part is actually used in the routine. - VSL_MATRIX_STORAGE_PACKED— lower triangle elements of T are packed by rows into a one-dimensional array. - VSL_MATRIX_STORAGE_DIAGONAL— only diagonal elements of T are passed.
a	const float* for vsRngGaussianMV const double* for vdRngGaussianMV	Mean vector a of dimension d
t	const float* for vsRngGaussianMV const double* for vdRngGaussianMV	Elements of the lower triangular matrix passed according to the matrix T storage scheme <i>mstorage</i> .

Output Parameters

Name	Type	Description
r	float* for vsRngGaussianMV double* for vdRngGaussianMV	Array of n random vectors of dimension <i>dimen</i>

Description

The `vsRngGaussianMV` function generates random numbers with d -variate normal (Gaussian) distribution with mean value a and variance-covariance matrix C , where $a \in \mathbb{R}^d$; C is a $d \times d$ symmetric positive-definite matrix.

The probability density function is given by:

$$f_{a,C}(x) = \frac{1}{\sqrt{\det(2\pi C)}} \exp(-1/2(x-a)^T C^{-1}(x-a)),$$

where $x \in \mathbb{R}^d$.

Matrix C can be represented as $C = TT^T$, where T is a lower triangular matrix - Cholesky factor of C .

Instead of variance-covariance matrix C the generation routines require Cholesky factor of C in input. To compute Cholesky factor of matrix C , the user may call Intel MKL LAPACK routines for matrix factorization: `?potrf` or `?pptrf` for `v?RngGaussianMV/v?rnggaussianmv` routines (`?` means either `s` or `d` for single and double precision respectively). See [Application Notes](#) for more details.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-

Optimization Notice

dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Application Notes

Since matrices are stored in Fortran by columns, while in C they are stored by rows, the usage of Intel MKL factorization routines (assuming Fortran matrices storage) in combination with multivariate normal RNG (assuming C matrix storage) is slightly different in C and Fortran. The following tables help in using these routines in C and Fortran. For further information please refer to the appropriate VS example file.

Using Cholesky Factorization Routines in C

Matrix Storage Scheme	Variance-Covariance Matrix Argument	Factorization Routine	UPLO Parameter in Factorization Routine	Result of Factorization as Input Argument for RNG
VSL_MATRIX_STORAGE_FULL	C in C two-dimensional array	spotrf for vsRngGaussianMV dpotrf for vdRngGaussianMV	'U'	Lower triangle of T . Upper triangle is not used.
VSL_MATRIX_STORAGE_PACKED	Lower triangle of C packed by columns into one-dimensional array	spptrf for vsRngGaussianMV dpptrf for vdRngGaussianMV	'L'	Lower triangle of T packed by columns into a one-dimensional array.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> nmax$.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.

VSL_RNG_ERROR_ARS5_NOT_SUPPORTED

ARS-5 random number generator is not supported on the CPU running the application.

vRngExponential

Generates exponentially distributed random numbers.

Syntax

```
status = vsRngExponential( method, stream, n, r, a, beta );
```

```
status = vdRngExponential( method, stream, n, r, a, beta );
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>method</i>	const MKL_INT	Generation method. The specific values are as follows: VSL_RNG_METHOD_EXPONENTIAL_ICDF VSL_RNG_METHOD_EXPONENTIAL_ICDF_ACCURATE Inverse cumulative distribution function method
<i>stream</i>	VSLStreamStatePtr	Pointer to the stream state structure
<i>n</i>	const MKL_INT	Number of random values to be generated
<i>a</i>	const float for vsRngExponential const double for vdRngExponential	Displacement <i>a</i>
<i>beta</i>	const float for vsRngExponential const double for vdRngExponential	Scalefactor β .

Output Parameters

Name	Type	Description
<i>r</i>	float* for vsRngExponential double* for vdRngExponential	Vector of <i>n</i> exponentially distributed random numbers

Description

The `vsRngExponential` function generates random numbers with exponential distribution that has displacement *a* and scalefactor β , where $a, \beta \in \mathbb{R}$; $\beta > 0$.

The probability density function is given by:

$$f_{a,\beta}(x) = \begin{cases} \frac{1}{\beta} \exp(-(x-a)/\beta), & x \geq a \\ 0, & x < a \end{cases}, -\infty < x < +\infty.$$

The cumulative distribution function is as follows:

$$F_{a,\beta}(x) = \begin{cases} 1 - \exp(-(x-a)/\beta), & x \geq a \\ 0, & x < a \end{cases}, -\infty < x < +\infty.$$

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

vRngLaplace

Generates random numbers with Laplace distribution.

Syntax

```
status = vsRngLaplace( method, stream, n, r, a, beta );
status = vdRngLaplace( method, stream, n, r, a, beta );
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>method</i>	const MKL_INT	Generation method. The specific values are as follows: VSL_RNG_METHOD_LAPLACE_ICDF Inverse cumulative distribution function method
<i>stream</i>	VSLStreamStatePtr	Pointer to the stream state structure
<i>n</i>	const MKL_INT	Number of random values to be generated
<i>a</i>	const float for vsRngLaplace const double for vdRngLaplace	Mean value <i>a</i>
<i>beta</i>	const float for vsRngLaplace const double for vdRngLaplace	Scalefactor β .

Output Parameters

Name	Type	Description
<i>r</i>	float* for vsRngLaplace double* for vdRngLaplace	Vector of <i>n</i> Laplace distributed random numbers

Description

The `vsRngLaplace` function generates random numbers with Laplace distribution with mean value (or average) *a* and scalefactor β , where $a, \beta \in \mathbb{R}$; $\beta > 0$. The scalefactor value determines the standard deviation as

The probability density function is given by:

$$f_{a,\beta}(x) = \frac{1}{\sqrt{2\beta}} \exp\left(-\frac{|x-a|}{\beta}\right), -\infty < x < +\infty.$$

The cumulative distribution function is as follows:

$$f_{a,\beta}(x) = \begin{cases} \frac{1}{2} \exp\left(-\frac{|x-a|}{\beta}\right), & x \geq a \\ 1 - \frac{1}{2} \exp\left(-\frac{|x-a|}{\beta}\right), & x < a \end{cases}, -\infty < x < +\infty.$$

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Notice revision #20110804

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

vRngWeibull

Generates Weibull distributed random numbers.

Syntax

```
status = vsRngWeibull( method, stream, n, r, alpha, a, beta );
status = vdRngWeibull( method, stream, n, r, alpha, a, beta );
```

Include Files

- `mk1.h`

Input Parameters

Name	Type	Description
<i>method</i>	<code>const MKL_INT</code>	Generation method. The specific values are as follows: <code>VSL_RNG_METHOD_WEIBULL_ICDF</code> <code>VSL_RNG_METHOD_WEIBULL_ICDF_ACCURATE</code> Inverse cumulative distribution function method
<i>stream</i>	<code>VSLStreamStatePtr</code>	Pointer to the stream state structure
<i>n</i>	<code>const MKL_INT</code>	Number of random values to be generated
<i>alpha</i>	<code>const float</code> for <code>vsRngWeibull</code> <code>const double</code> for <code>vdRngWeibull</code>	Shape α .
<i>a</i>	<code>const float</code> for <code>vsRngWeibull</code> <code>const double</code> for <code>vdRngWeibull</code>	Displacement a
<i>beta</i>	<code>const float</code> for <code>vsRngWeibull</code> <code>const double</code> for <code>vdRngWeibull</code>	Scalefactor β .

Output Parameters

Name	Type	Description
<i>r</i>	<code>float*</code> for <code>vsRngWeibull</code> <code>double*</code> for <code>vdRngWeibull</code>	Vector of n Weibull distributed random numbers

Description

The `vsRngWeibull` function generates Weibull distributed random numbers with displacement a , scalefactor β , and shape α , where $\alpha, \beta, a \in \mathbb{R}$; $\alpha > 0, \beta > 0$.

The probability density function is given by:

$$f_{\alpha, \beta, a}(x) = \begin{cases} \frac{\alpha}{\beta^\alpha} (x - a)^{\alpha-1} \exp\left(-\left(\frac{x - a}{\beta}\right)^\alpha\right), & x \geq a \\ 0, & x < a \end{cases}$$

The cumulative distribution function is as follows:

$$F_{a,\alpha,\beta}(x) = \begin{cases} 1 - \exp\left(-\left(\frac{x-a}{\beta}\right)^\alpha\right), & x \geq a \\ 0, & x < a \end{cases}, -\infty < x < +\infty.$$

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

vRngCauchy

Generates Cauchy distributed random values.

Syntax

```
status = vsRngCauchy( method, stream, n, r, a, beta );
```

```
status = vdRngCauchy( method, stream, n, r, a, beta );
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>method</i>	const MKL_INT	Generation method. The specific values are as follows: VSL_RNG_METHOD_CAUCHY_ICDF Inverse cumulative distribution function method
<i>stream</i>	VSLStreamStatePtr	Pointer to the stream state structure
<i>n</i>	const MKL_INT	Number of random values to be generated
<i>a</i>	const float for vsRngCauchy const double for vdRngCauchy	Displacement <i>a</i> .
<i>beta</i>	const float for vsRngCauchy const double for vdRngCauchy	Scalefactor <i>β</i> .

Output Parameters

Name	Type	Description
<i>r</i>	float* for vsRngCauchy double* for vdRngCauchy	Vector of <i>n</i> Cauchy distributed random numbers

Description

The function generates Cauchy distributed random numbers with displacement *a* and scalefactor *β*, where *a*, *β* ∈ *R* ; *β* > 0.

The probability density function is given by:

$$f_{a,\beta}(x) = \frac{1}{\pi\beta \left(1 + \left(\frac{x - a}{\beta}\right)^2\right)}, -\infty < x < +\infty.$$

The cumulative distribution function is as follows:

$$F_{a,\beta}(x) = \frac{1}{2} + \frac{1}{\pi} \arctan\left(\frac{x - a}{\beta}\right), -\infty < x < +\infty.$$

Optimization Notice
Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

vRngRayleigh

Generates Rayleigh distributed random values.

Syntax

```
status = vsRngRayleigh( method, stream, n, r, a, beta );
status = vdRngRayleigh( method, stream, n, r, a, beta );
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>method</i>	const MKL_INT	Generation method. The specific values are as follows: VSL_RNG_METHOD_RAYLEIGH_ICDF VSL_RNG_METHOD_RAYLEIGH_ICDF_ACCURATE Inverse cumulative distribution function method
<i>stream</i>	VSLStreamStatePtr	Pointer to the stream state structure
<i>n</i>	const MKL_INT	Number of random values to be generated

Name	Type	Description
<i>a</i>	const float for vsRngRayleigh const double for vdRngRayleigh	Displacement <i>a</i>
<i>beta</i>	const float for vsRngRayleigh const double for vdRngRayleigh	Scalefactor β .

Output Parameters

Name	Type	Description
<i>r</i>	float* for vsRngRayleigh double* for vdRngRayleigh	Vector of <i>n</i> Rayleigh distributed random numbers

Description

The `vsRngRayleigh` function generates Rayleigh distributed random numbers with displacement *a* and scalefactor β , where $a, \beta \in R ; \beta > 0$.

The Rayleigh distribution is a special case of the `Weibull` distribution, where the shape parameter $\alpha = 2$.

The probability density function is given by:

$$f_{a,\beta}(x) = \begin{cases} \frac{2(x-a)}{\beta^2} \exp\left(-\frac{(x-a)^2}{\beta^2}\right), & x \geq a \\ 0, & x < a \end{cases}, -\infty < x < +\infty.$$

The cumulative distribution function is as follows:

$$F_{a,\beta}(x) = \begin{cases} 1 - \exp\left(-\frac{(x-a)^2}{\beta^2}\right), & x \geq a \\ 0, & x < a \end{cases}, -\infty < x < +\infty.$$

Optimization Notice

Notice revision #20110804

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

vRngLognormal

Generates lognormally distributed random numbers.

Syntax

```
status = vsRngLognormal( method, stream, n, r, a, sigma, b, beta );
status = vdRngLognormal( method, stream, n, r, a, sigma, b, beta );
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>method</i>	const MKL_INT	Generation method. The specific values are as follows: VSL_RNG_METHOD_LOGNORMAL_BOXMULLER2 VSL_RNG_METHOD_LOGNORMAL_BOXMULLER2_ACCURATE Box Muller 2 based method VSL_RNG_METHOD_LOGNORMAL_ICDF VSL_RNG_METHOD_LOGNORMAL_ICDF_ACCURATE

Name	Type	Description
		Inverse cumulative distribution function based method
<i>stream</i>	VSLStreamStatePtr	Pointer to the stream state structure
<i>n</i>	const MKL_INT	Number of random values to be generated
<i>a</i>	const float for vsRngLognormal const double for vdRngLognormal	Average <i>a</i> of the subject normal distribution
<i>sigma</i>	const float for vsRngLognormal const double for vdRngLognormal	Standard deviation σ of the subject normal distribution
<i>b</i>	const float for vsRngLognormal const double for vdRngLognormal	Displacement <i>b</i>
<i>beta</i>	const float for vsRngLognormal const double for vdRngLognormal	Scalefactor β .

Output Parameters

Name	Type	Description
<i>r</i>	float* for vsRngLognormal double* for vdRngLognormal	Vector of <i>n</i> lognormally distributed random numbers

Description

The `vsRngLognormal` function generates lognormally distributed random numbers with average of distribution *a* and standard deviation σ of subject normal distribution, displacement *b*, and scalefactor β , where *a*, σ , *b*, $\beta \in \mathbb{R}$; $\sigma > 0$, $\beta > 0$.

The probability density function is given by:

$$f_{a,\sigma,b,\beta}(x) = \begin{cases} \frac{1}{\sigma(x-b)\sqrt{2\pi}} \exp\left(-\frac{[\ln((x-b)/\beta) - a]^2}{2\sigma^2}\right), & x > b \\ 0, & x \leq b \end{cases}$$

The cumulative distribution function is as follows:

$$F_{a,\sigma,b,\beta}(x) = \begin{cases} \Phi((\ln((x-b)/\beta) - a)/\sigma), & x > b \\ 0, & x \leq b \end{cases}$$

Optimization Notice

Notice revision #20110804

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

vRngGumbel

Generates Gumbel distributed random values.

Syntax

```
status = vsRngGumbel( method, stream, n, r, a, beta );
status = vdRngGumbel( method, stream, n, r, a, beta );
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>method</i>	const MKL_INT	Generation method. The specific values are as follows: VSL_RNG_METHOD_GUMBEL_ICDF Inverse cumulative distribution function method
<i>stream</i>	VSLStreamStatePtr	Pointer to the stream state structure
<i>n</i>	const MKL_INT	Number of random values to be generated
<i>a</i>	const float for vsRngGumbel const double for vdRngGumbel	Displacement <i>a</i> .
<i>beta</i>	const float for vsRngGumbel const double for vdRngGumbel	Scalefactor <i>β</i> .

Output Parameters

Name	Type	Description
<i>r</i>	float* for vsRngGumbel double* for vdRngGumbel	Vector of <i>n</i> random numbers with Gumbel distribution

Description

The `vsRngGumbel` function generates Gumbel distributed random numbers with displacement *a* and scalefactor *β*, where *a*, *β* ∈ *R* ; *β* > 0.

The probability density function is given by:

$$f_{a,\beta}(x) = \left\{ \frac{1}{\beta} \exp \left(\frac{x - a}{\beta} \right) \exp \left(- \exp \left((x - a) / \beta \right) \right), -\infty < x < +\infty . \right.$$

The cumulative distribution function is as follows:

$$F_{a,\beta}(x) = 1 - \exp \left(- \exp \left((x - a) / \beta \right) \right), -\infty < x < +\infty$$

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. Optimization Notice

Notice revision #20110804

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

vRngGamma*Generates gamma distributed random values.***Syntax**

```
status = vsRngGamma( method, stream, n, r, alpha, a, beta );
status = vdRngGamma( method, stream, n, r, alpha, a, beta );
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>method</i>	const MKL_INT	Generation method. The specific values are as follows: VSL_RNG_METHOD_GAMMA_GNORM VSL_RNG_METHOD_GAMMA_GNORM_ACCURATE Acceptance/rejection method using random numbers with Gaussian distribution. See brief description of the method GNORM in Table "Values of <method> in method parameter"
<i>stream</i>	VSLStreamStatePtr	Pointer to the stream state structure
<i>n</i>	const MKL_INT	Number of random values to be generated

Name	Type	Description
<i>alpha</i>	const float for vsRngGamma const double for vdRngGamma	Shape α .
<i>a</i>	const float for vsRngGamma const double for vdRngGamma	Displacement a .
<i>beta</i>	const float for vsRngGamma const double for vdRngGamma	Scale factor β .

Output Parameters

Name	Type	Description
<i>r</i>	float* for vsRngGamma double* for vdRngGamma	Vector of n random numbers with gamma distribution

Description

The `vsRngGamma` function generates random numbers with gamma distribution that has shape parameter α , displacement a , and scale parameter β , where α, β , and $a \in \mathbb{R}$; $\alpha > 0$, $\beta > 0$.

The probability density function is given by:

$$f_{\alpha,a,\beta}(x) = \begin{cases} \frac{1}{\Gamma(\alpha)\beta^\alpha} (x - a)^{\alpha-1} e^{-(x-a)/\beta}, & x \geq a \\ 0, & x < a \end{cases}, -\infty < x < +\infty$$

where $\Gamma(\alpha)$ is the complete gamma function.

The cumulative distribution function is as follows:

$$F_{\alpha,a,\beta}(x) = \begin{cases} \int_a^x \frac{1}{\Gamma(\alpha)\beta^\alpha} (y - a)^{\alpha-1} e^{-(y-a)/\beta} dy, & x \geq a \\ 0, & x < a \end{cases}, -\infty < x < +\infty$$

Optimization Notice
Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice. Notice revision #20110804

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

vRngBeta

Generates beta distributed random values.

Syntax

```
status = vsRngBeta( method, stream, n, r, p, q, a, beta );
```

```
status = vdRngBeta( method, stream, n, r, p, q, a, beta );
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>method</i>	const MKL_INT	Generation method. The specific values are as follows: VSL_RNG_METHOD_BETA_CJA VSL_RNG_METHOD_BETA_CJA_ACCURATE See brief description of the method CJA in Table "Values of <method> in method parameter"
<i>stream</i>	VSLStreamStatePtr	Pointer to the stream state structure
<i>n</i>	const MKL_INT	Number of random values to be generated
<i>p</i>	const float for vsRngBeta const double for vdRngBeta	Shape <i>p</i>
<i>q</i>	const float for vsRngBeta	Shape <i>q</i>

Name	Type	Description
	const double for vdRngBeta	
<i>a</i>	const float for vsRngBeta const double for vdRngBeta	Displacement <i>a</i> .
<i>beta</i>	const float for vsRngBeta const double for vdRngBeta	Scalefactor <i>β</i> .

Output Parameters

Name	Type	Description
<i>r</i>	float* for vsRngBeta double* for vdRngBeta	Vector of <i>n</i> random numbers with beta distribution

Description

The `vdRngBeta` function generates random numbers with beta distribution that has shape parameters *p* and *q*, displacement *a*, and scale parameter *β*, where *p*, *q*, *a*, and *β* ∈ ℝ ; *p* > 0, *q* > 0, *β* > 0.

The probability density function is given by:

$$f_{p,q,a,\beta}(x) = \begin{cases} \frac{1}{B(p,q)\beta^{p+q-1}} (x-a)^{p-1}(\beta+a-x)^{q-1}, & a \leq x < a+\beta \\ 0, & x < a, x \geq a+\beta \end{cases}, -\infty < x < \infty,$$

where *B*(*p*, *q*) is the complete beta function.

The cumulative distribution function is as follows:

$$F_{p,q,a,\beta}(x) = \begin{cases} 0, & x < a \\ \int_a^x \frac{1}{B(p,q)\beta^{p+q-1}} (y-a)^{p-1}(\beta+a-y)^{q-1} dy, & a \leq x < a+\beta \\ 1, & x \geq a+\beta \end{cases}, -\infty < x < \infty.$$

Optimization Notice
Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice. Notice revision #20110804

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEED ED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

Discrete Distributions

This section describes routines for generating random numbers with discrete distribution.

vRngUniform

Generates random numbers uniformly distributed over the interval $[a, b)$.

Syntax

```
status = viRngUniform( method, stream, n, r, a, b );
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>method</i>	const MKL_INT	Generation method; the specific value is as follows: VSL_RNG_METHOD_UNIFORM_STD
<i>stream</i>	VSLStreamStatePtr	Pointer to the stream state structure
<i>n</i>	const MKL_INT	Number of random values to be generated
<i>a</i>	const int	Left interval bound a
<i>b</i>	const int	Right interval bound b

Output Parameters

Name	Type	Description
r	<code>int*</code>	Vector of n random numbers uniformly distributed over the interval $[a, b)$

Description

The `vRngUniform` function generates random numbers uniformly distributed over the interval $[a, b)$, where a, b are the left and right bounds of the interval respectively, and $a, b \in \mathbb{Z}; a < b$.

The probability distribution is given by:

$$P(X = k) = \frac{1}{b - a}, k \in \{a, a + 1, \dots, b - 1\}.$$

The cumulative distribution function is as follows:

$$F_{a,b}(x) = \begin{cases} 0, & x < a \\ \frac{\lfloor x - a + 1 \rfloor}{b - a}, & a \leq x < b, x \in \mathbb{R}. \\ 1, & x \geq b \end{cases}$$

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Return Values

<code>VSL_ERROR_OK, VSL_STATUS_OK</code>	Indicates no error, execution is successful.
<code>VSL_ERROR_NULL_PTR</code>	<i>stream</i> is a <code>NULL</code> pointer.
<code>VSL_RNG_ERROR_BAD_STREAM</code>	<i>stream</i> is not a valid random stream.
<code>VSL_RNG_ERROR_BAD_UPDATE</code>	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> nmax$.

VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

vRngUniformBits

Generates bits of underlying BRNG integer recurrence.

Syntax

```
status = viRngUniformBits( method, stream, n, r );
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>method</i>	const MKL_INT	Generation method; the specific value is <code>VSL_RNG_METHOD_UNIFORMBITS_STD</code>
<i>stream</i>	VSLStreamStatePtr	Pointer to the stream state structure
<i>n</i>	const MKL_INT	Number of random values to be generated

Output Parameters

Name	Type	Description
<i>r</i>	unsigned int*	Vector of <i>n</i> random integer numbers. If the <i>stream</i> was generated by a 64 or a 128-bit generator, each integer value is represented by two or four elements of <i>r</i> respectively. The number of bytes occupied by each integer is contained in the field <i>WordSize</i> of the structure <code>VSLBRngProperties</code> . The total number of bits that are actually used to store the value are contained in the field <i>NBits</i> of the same structure. See Advanced Service Routines for a more detailed discussion of <code>VSLBRngProperties</code> .

Description

The `viRngUniformBits` function generates integer random values with uniform bit distribution. The generators of uniformly distributed numbers can be represented as recurrence relations over integer values in modular arithmetic. Apparently, each integer can be treated as a vector of several bits. In a truly random generator, these bits are random, while in pseudorandom generators this randomness can be violated. For example, a well known drawback of linear congruential generators is that lower bits are less random than higher bits (for example, see [Knuth81]). For this reason, care should be taken when using this function. Typically, in a 32-bit LCG only 24 higher bits of an integer value can be considered random. See [VS Notes](#) for details.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Return Values

<code>VSL_ERROR_OK, VSL_STATUS_OK</code>	Indicates no error, execution is successful.
<code>VSL_ERROR_NULL_PTR</code>	<i>stream</i> is a <code>NULL</code> pointer.
<code>VSL_RNG_ERROR_BAD_STREAM</code>	<i>stream</i> is not a valid random stream.
<code>VSL_RNG_ERROR_BAD_UPDATE</code>	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> nmax$.
<code>VSL_RNG_ERROR_NO_NUMBERS</code>	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
<code>VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED</code>	Period of the generator has been exceeded.
<code>VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEED</code>	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.
<code>VSL_RNG_ERROR_ARS5_NOT_SUPPORTED</code>	ARS-5 random number generator is not supported on the CPU running the application.

vRngUniformBits32

Generates uniformly distributed bits in 32-bit chunks.

Syntax

```
status = viRngUniformBits32( method, stream, n, r );
```

Include Files

- `mk1.h`

Input Parameters

Name	Type	Description
<i>method</i>	<code>const MKL_INT</code>	Generation method; the specific value is <code>VSL_RNG_METHOD_UNIFORMBITS32_STD</code>
<i>stream</i>	<code>VSLStreamStatePtr</code>	Pointer to the stream state structure

Name	Type	Description
<i>n</i>	const MKL_INT	Number of random values to be generated

Output Parameters

Name	Type	Description
<i>r</i>	unsigned int*	Vector of <i>n</i> 32-bit random integer numbers with uniform bit distribution.

Description

The `vRngUniformBits32` function generates uniformly distributed bits in 32-bit chunks. Unlike `vRngUniformBits`, which provides the output of underlying integer recurrence and does not guarantee uniform distribution across bits, `vRngUniformBits32` is designed to ensure each bit in the 32-bit chunk is uniformly distributed. See [VS Notes](#) for details.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BRNG_NOT_SUPPORTED	BRNG is not supported by the function.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

vRngUniformBits64

Generates uniformly distributed bits in 64-bit chunks.

Syntax

```
status = viRngUniformBits64( method, stream, n, r );
```

Include Files

- `mkh.h`

Input Parameters

Name	Type	Description
<i>method</i>	const MKL_INT	Generation method; the specific value is <code>VSL_RNG_METHOD_UNIFORMBITS64_STD</code>
<i>stream</i>	VSLStreamStatePtr	Pointer to the stream state structure
<i>n</i>	const MKL_INT	Number of random values to be generated

Output Parameters

Name	Type	Description
<i>r</i>	unsigned MKL_INT64*	Vector of <i>n</i> 64-bit random integer numbers with uniform bit distribution.

Description

The `vRngUniformBits64` function generates uniformly distributed bits in 64-bit chunks. Unlike `vRngUniformBits`, which provides the output of underlying integer recurrence and does not guarantee uniform distribution across bits, `vRngUniformBits64` is designed to ensure each bit in the 64-bit chunk is uniformly distributed. See [VS Notes](#) for details.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. <code>VSL_ERROR_NULL_PTR</code>	<i>stream</i> is a NULL pointer.
<code>VSL_RNG_ERROR_BAD_STREAM</code>	<i>stream</i> is not a valid random stream.
<code>VSL_RNG_ERROR_BRNG_NOT_SUPPORTED</code>	BRNG is not supported by the function.
<code>VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED</code>	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.
<code>VSL_RNG_ERROR_ARS5_NOT_SUPPORTED</code>	ARS-5 random number generator is not supported on the CPU running the application.

vRngBernoulli

Generates Bernoulli distributed random values.

Syntax

```
status = viRngBernoulli( method, stream, n, r, p );
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>method</i>	const MKL_INT	Generation method. The specific value is as follows: VSL_RNG_METHOD_BERNOULLI_ICDF Inverse cumulative distribution function method.
<i>stream</i>	VSLStreamStatePtr	Pointer to the stream state structure
<i>n</i>	const MKL_INT	Number of random values to be generated
<i>p</i>	const double	Success probability p of a trial

Output Parameters

Name	Type	Description
<i>r</i>	int*	Vector of n Bernoulli distributed random values

Description

The `viRngBernoulli` function generates Bernoulli distributed random numbers with probability p of a single trial success, where

$p \in \mathbb{R}; 0 \leq p \leq 1$.

A variate is called Bernoulli distributed, if after a trial it is equal to 1 with probability of success p , and to 0 with probability $1 - p$.

The probability distribution is given by:

$P(X = 1) = p$

$P(X = 0) = 1 - p$

The cumulative distribution function is as follows:

$$F_p(x) = \begin{cases} 0, & x < 0 \\ 1 - p, & 0 \leq x < 1, x \in \mathbb{R}. \\ 1, & x \geq 1 \end{cases}$$

Optimization Notice

Notice revision #20110804

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> nmax$.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

vRngGeometric

Generates geometrically distributed random values.

Syntax

```
status = viRngGeometric( method, stream, n, r, p );
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>method</i>	const MKL_INT	Generation method. The specific value is as follows: VSL_RNG_METHOD_GEOMETRIC_ICDF Inverse cumulative distribution function method.
<i>stream</i>	VSLStreamStatePtr	Pointer to the stream state structure
<i>n</i>	const MKL_INT	Number of random values to be generated
<i>p</i>	const double	Success probability p of a trial

Output Parameters

Name	Type	Description
r	int*	Vector of n geometrically distributed random values

Description

The `vRngGeometric` function generates geometrically distributed random numbers with probability p of a single trial success, where $p \in \mathbb{R}$; $0 < p < 1$.

A geometrically distributed variate represents the number of independent Bernoulli trials preceding the first success. The probability of a single Bernoulli trial success is p .

The probability distribution is given by:

$$P(X = k) = p \cdot (1 - p)^k, k \in \{0, 1, 2, \dots\}.$$

The cumulative distribution function is as follows:

$$F_p(x) = \begin{cases} 0, & x < 0 \\ 1 - (1 - p)^{\lfloor x+1 \rfloor}, & 0 \leq x \end{cases} \quad x \in \mathbb{R}.$$

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Notice revision #20110804

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> nmax$.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.

VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEED ED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

vRngBinomial
Generates binomially distributed random numbers.

Syntax

```
status = viRngBinomial( method, stream, n, r, ntrial, p );
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>method</i>	const MKL_INT	Generation method. The specific value is as follows: VSL_RNG_METHOD_BINOMIAL_BTPE See brief description of the BTPE method in Table "Values of <method> in method parameter" .
<i>stream</i>	VSLStreamStatePtr	Pointer to the stream state structure
<i>n</i>	const MKL_INT	Number of random values to be generated
<i>ntrial</i>	const int	Number of independent trials m
<i>p</i>	const double	Success probability p of a single trial

Output Parameters

Name	Type	Description
<i>r</i>	int*	Vector of n binomially distributed random values

Description

The `viRngBinomial` function generates binomially distributed random numbers with number of independent Bernoulli trials m , and with probability p of a single trial success, where $p \in R$; $0 \leq p \leq 1$, $m \in N$.

A binomially distributed variate represents the number of successes in m independent Bernoulli trials with probability of a single trial success p .

The probability distribution is given by:

$$P(X = k) = C_m^k p^k (1 - p)^{m-k}, k \in \{0, 1, \dots, m\}.$$

The cumulative distribution function is as follows:

$$F_{m,p}(x) = \begin{cases} 0, & x < 0 \\ \sum_{k=0}^{\lfloor x \rfloor} C_m^k p^k (1-p)^{m-k}, & 0 \leq x < m, x \in \mathbb{R} \\ 1, & x \geq m \end{cases}$$

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

vRngHypergeometric

Generates hypergeometrically distributed random values.

Syntax

```
status = viRngHypergeometric( method, stream, n, r, l, s, m );
```

Include Files

- `mk1.h`

Input Parameters

Name	Type	Description
<i>method</i>	<code>const MKL_INT</code>	Generation method. The specific value is as follows: <code>VSL_RNG_METHOD_HYPERGEOMETRIC_H2PE</code> See brief description of the H2PE method in Table "Values of <method> in method parameter"
<i>stream</i>	<code>VSLStreamStatePtr</code>	Pointer to the stream state structure
<i>n</i>	<code>const MKL_INT</code>	Number of random values to be generated
<i>l</i>	<code>const int</code>	Lot size l
<i>s</i>	<code>const int</code>	Size of sampling without replacement s
<i>m</i>	<code>const int</code>	Number of marked elements m

Output Parameters

Name	Type	Description
<i>r</i>	<code>int*</code>	Vector of n hypergeometrically distributed random values

Description

The `vRngHypergeometric` function generates hypergeometrically distributed random values with lot size l , size of sampling s , and number of marked elements in the lot m , where $l, m, s \in \mathbb{N} \cup \{0\}$; $l \geq \max(s, m)$.

Consider a lot of l elements comprising m "marked" and $l-m$ "unmarked" elements. A trial sampling without replacement of exactly s elements from this lot helps to define the hypergeometric distribution, which is the probability that the group of s elements contains exactly k marked elements.

The probability distribution is given by:)

$$P(X = k) = \frac{C_m^k C_{l-m}^{s-k}}{C_l^s}$$

, $k \in \{\max(0, s + m - l), \dots, \min(s, m)\}$

The cumulative distribution function is as follows:

$$F_{l,s,m}(x) = \begin{cases} 0, & x < \max(0, s + m - l) \\ \sum_{k=\max(0, s+m-l)}^{\lfloor x \rfloor} \frac{C_m^k C_{l-m}^{s-k}}{C_l^s}, & \max(0, s + m - l) \leq x \leq \min(s, m) \\ 1, & x > \min(s, m) \end{cases}$$

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Notice revision #20110804

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

vRngPoisson

Generates Poisson distributed random values.

Syntax

```
status = viRngPoisson( method, stream, n, r, lambda );
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>method</i>	const MKL_INT	Generation method. The specific values are as follows: VSL_RNG_METHOD_POISSON_PTPE VSL_RNG_METHOD_POISSON_POISNORM

Name	Type	Description
		See brief description of the PTPE and POISNORM methods in Table "Values of <method> in method parameter".
<i>stream</i>	VSLStreamStatePtr	Pointer to the stream state structure
<i>n</i>	const MKL_INT	Number of random values to be generated
<i>lambda</i>	const double	Distribution parameter λ .

Output Parameters

Name	Type	Description
<i>r</i>	int*	Vector of <i>n</i> Poisson distributed random values

Description

The `vRng"Poisson"` function generates Poisson distributed random numbers with distribution parameter λ , where $\lambda \in R$; $\lambda > 0$.

The probability distribution is given by:

$$P(X=k) = \frac{\lambda^k e^{-\lambda}}{k!}, \quad k \in \{0, 1, 2, \dots\}.$$

$k \in \{0, 1, 2, \dots\}$.

The cumulative distribution function is as follows:

$$F_{\lambda}(x) = \begin{cases} \sum_{k=0}^{\lfloor x \rfloor} \frac{\lambda^k e^{-\lambda}}{k!}, & x \geq 0 \\ 0, & x < 0 \end{cases}, x \in R$$

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.

VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or $> nmax$.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEED ED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

vRngPoissonV

Generates Poisson distributed random values with varying mean.

Syntax

```
status = viRngPoissonV( method, stream, n, r, lambda );
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>method</i>	const MKL_INT	Generation method. The specific value is as follows: <code>VSL_RNG_METHOD_POISSONV_POISNORM</code> See brief description of the POISNORM method in Table "Values of <method> in method parameter"
<i>stream</i>	VSLStreamStatePtr	Pointer to the stream state structure
<i>n</i>	const MKL_INT	Number of random values to be generated
<i>lambda</i>	const double*	Array of n distribution parameters λ_i .

Output Parameters

Name	Type	Description
<i>r</i>	int*	Vector of n Poisson distributed random values

Description

The `viRngPoissonV` function generates n Poisson distributed random numbers $x_i (i = 1, \dots, n)$ with distribution parameter λ_i , where $\lambda_i \in R; \lambda_i > 0$.

The probability distribution is given by:

$$P(X_i = k) = \frac{\lambda_i^k \exp(-\lambda_i)}{k!}, k \in \{0, 1, 2, \dots\}.$$

The cumulative distribution function is as follows:

$$F_{\lambda_i}(x) = \begin{cases} \sum_{k=0}^{\lfloor x \rfloor} \frac{\lambda_i^k e^{-\lambda_i}}{k!}, & x \geq 0 \\ 0, & x < 0 \end{cases}, x \in \mathbb{R}$$

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_NONDETERM_NRETRIES_EXCEEDED	Number of retries to generate a random number by using non-deterministic random number generator exceeds threshold.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

vRngNegBinomial

Generates random numbers with negative binomial distribution.

Syntax

```
status = viRngNegbinomial( method, stream, n, r, a, p );
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>method</i>	const MKL_INT	Generation method. The specific value is: VSL_RNG_METHOD_NEGBINOMIAL_NBAR See brief description of the NBAR method in Table "Values of <method> in method parameter"
<i>stream</i>	VSLStreamStatePtr	pointer to the stream state structure
<i>n</i>	const MKL_INT	Number of random values to be generated
<i>a</i>	const double	The first distribution parameter <i>a</i>
<i>p</i>	const double	The second distribution parameter <i>p</i>

Output Parameters

Name	Type	Description
<i>r</i>	int*	Vector of <i>n</i> random values with negative binomial distribution.

Description

The `vRngNegBinomial` function generates random numbers with negative binomial distribution and distribution parameters *a* and *p*, where $p, a \in \mathbb{R}$; $0 < p < 1$; $a > 0$.

If the first distribution parameter $a \in \mathbb{N}$, this distribution is the same as Pascal distribution. If $a \in \mathbb{N}$, the distribution can be interpreted as the expected time of *a*-th success in a sequence of Bernoulli trials, when the probability of success is *p*.

The probability distribution is given by:

$$P(X = k) = C_{a+k-1}^k p^a (1 - p)^k, k \in \{0, 1, 2, \dots\}.$$

The cumulative distribution function is as follows:

$$F_{a,p}(x) = \begin{cases} \sum_{k=0}^{\lfloor x \rfloor} C_{a+k-1}^k p^a (1 - p)^k, & x \geq 0 \\ 0, & x < 0 \end{cases}, x \in \mathbb{R}$$

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_ERROR_NULL_PTR	<i>stream</i> is a NULL pointer.
VSL_RNG_ERROR_BAD_STREAM	<i>stream</i> is not a valid random stream.
VSL_RNG_ERROR_BAD_UPDATE	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_RNG_ERROR_NO_NUMBERS	Callback function for an abstract BRNG returns 0 as the number of updated entries in a buffer.
VSL_RNG_ERROR_QRNG_PERIOD_ELAPSED	Period of the generator has been exceeded.
VSL_RNG_ERROR_ARS5_NOT_SUPPORTED	ARS-5 random number generator is not supported on the CPU running the application.

Advanced Service Routines

This section describes service routines for registering a user-designed basic generator ([vslRegisterBrng](#)) and for obtaining properties of the previously registered basic generators ([vslGetBrngProperties](#)). See [VS Notes](#) ("Basic Generators" section of VS Structure chapter) for substantiation of the need for several basic generators including user-defined BRNGs.

Data types

The Advanced Service routines refer to a structure defining the properties of the basic generator.

This structure is described as follows:

```
typedef struct _VSLBRngProperties {
    int StreamStateSize;
    int NSeeds;
    int IncludesZero;
    int WordSize;
    int NBits;
    InitStreamPtr InitStream;
    sBRngPtr sBRng;
    dBRngPtr dBRng;
    iBRngPtr iBRng;
} VSLBRngProperties;
```

The following table provides brief descriptions of the fields engaged in the above structure:

Field Descriptions

Field	Short Description
StreamStateSize	The size, in bytes, of the stream state structure for a given basic generator.
NSeeds	The number of 32-bit initial conditions (seeds) necessary to initialize the stream state structure for a given basic generator.
IncludesZero	Flag value indicating whether the generator can produce a random 0.
WordSize	Machine word size, in bytes, used in integer-value computations. Possible values: 4, 8, and 16 for 32, 64, and 128-bit generators, respectively.
NBits	The number of bits required to represent a random value in integer arithmetic. Note that, for instance, 48-bit random values are stored to 64-bit (8 byte) memory locations. In this case, <code>wordsize/WordSize</code> is equal to 8 (number of bytes used to store the random value), while <code>nbits/NBits</code> contains the actual number of bits occupied by the value (in this example, 48).
InitStream	Contains the pointer to the initialization routine of a given basic generator.
sBRng	Contains the pointer to the basic generator of single precision real numbers uniformly distributed over the interval (a,b) (<code>float</code>).
dBRng	Contains the pointer to the basic generator of double precision real numbers uniformly distributed over the interval (a,b) (<code>double</code>).
iBRng	Contains the pointer to the basic generator of integer numbers with uniform bit distribution (<code>unsigned int</code>).

vslRegisterBrng

Registers user-defined basic generator.

Syntax

```
brng = vslRegisterBrng( &properties );
```

Include Files

- `mkl.h`

Input Parameters

Name	Type	Description
<code>properties</code>	<code>const VSLBRngProperties*</code>	Pointer to the structure containing properties of the basic generator to be registered

¹ A specific generator that permits operations over single bits and bit groups of random numbers.

Output Parameters

Name	Type	Description
<i>brng</i>	int	Number (index) of the registered basic generator; used for identification. Negative values indicate the registration error.

Description

An example of a registration procedure can be found in the respective directory of the VS examples.

Return Values

VSL_ERROR_OK, VSL_STATUS_OK	Indicates no error, execution is successful.
VSL_RNG_ERROR_BRNG_TABLE_FULL	Registration cannot be completed due to lack of free entries in the table of registered BRNGs.
VSL_RNG_ERROR_BAD_STREAM_STATE_SIZE	Bad value in <code>StreamStateSize</code> field.
VSL_RNG_ERROR_BAD_WORD_SIZE	Bad value in <code>WordSize</code> field.
VSL_RNG_ERROR_BAD_NSEEDS	Bad value in <code>NSeeds</code> field.
VSL_RNG_ERROR_BAD_NBITS	Bad value in <code>NBits</code> field.
VSL_ERROR_NULL_PTR	At least one of the fields <code>iBrng</code> , <code>dBrng</code> , <code>sBrng</code> or <code>InitStream</code> is a NULL pointer.

vslGetBrngProperties

Returns structure with properties of a given basic generator.

Syntax

```
status = vslGetBrngProperties( brng, &properties );
```

Include Files

- `mkl.h`

Input Parameters

Name	Type	Description
<i>brng</i>	const int	Number (index) of the registered basic generator; used for identification. See specific values in Table "Values of <i>brng</i> parameter" . Negative values indicate the registration error.

Output Parameters

Name	Type	Description
<i>properties</i>	VSLBRngProperties*	Pointer to the structure containing properties of the generator with number <i>brng</i>

Description

The `vslGetBrngProperties` function returns a structure with properties of a given basic generator.

Return Values

`VSL_ERROR_OK, VSL_STATUS_OK` Indicates no error, execution is successful.

`VSL_RNG_ERROR_INVALID_BRNG_INDEX` BRNG index is invalid.

Formats for User-Designed Generators

To register a user-designed basic generator using `vslRegisterBrng` function, you need to pass the pointer `iBrng` to the integer-value implementation of the generator; the pointers `sBrng` and `dBrng` to the generator implementations for single and double precision values, respectively; and pass the pointer `InitStream` to the stream initialization routine. See recommendations below on defining such functions with input and output arguments. An example of the registration procedure for a user-designed generator can be found in the respective directory of VS examples.

The respective pointers are defined as follows:

```
typedef int(*InitStreamPtr)( int method, VSLStreamStatePtr stream, int n, const unsigned int params[] );
```

```
typedef int(*sBrngPtr)( VSLStreamStatePtr stream, int n, float r[], float a, float b );
```

```
typedef int(*dBrngPtr)( VSLStreamStatePtr stream, int n, double r[], double a, double b );
```

```
typedef int(*iBrngPtr)( VSLStreamStatePtr stream, int n, unsigned int r[] );
```

InitStream

```
int MyBrngInitStream( int method, VSLStreamStatePtr stream, int n, const unsigned int params[] )
{
    /* Initialize the stream */
    ...
} /* MyBrngInitStream */
```

Description

The initialization routine of a user-designed generator must initialize *stream* according to the specified initialization *method*, initial conditions *params* and the argument *n*. The value of *method* determines the initialization method to be used.

- If *method* is equal to 1, the initialization is by the standard generation method, which must be supported by all basic generators. In this case the function assumes that the *stream* structure was not previously initialized. The value of *n* is used as the actual number of 32-bit values passed as initial conditions through *params*. Note, that the situation when the actual number of initial conditions passed to the function is not sufficient to initialize the generator is not an error. Whenever it occurs, the basic generator must initialize the missing conditions using default settings.
- If *method* is equal to 2, the generation is by the leapfrog method, where *n* specifies the number of computational nodes (independent streams). Here the function assumes that the *stream* was previously initialized by the standard generation method. In this case *params* contains only one element, which identifies the computational node. If the generator does not support the leapfrog method, the function must return the error code `VSL_RNG_ERROR_LEAPFROG_UNSUPPORTED`.
- If *method* is equal to 3, the generation is by the block-splitting method. Same as above, the *stream* is assumed to be previously initialized by the standard generation method; *params* is not used, *n* identifies the number of skipped elements. If the generator does not support the block-splitting method, the function must return the error code `VSL_RNG_ERROR_SKIPAHEAD_UNSUPPORTED`.

For a more detailed description of the leapfrog and the block-splitting methods, refer to the description of `vslLeapfrogStream` and `vslSkipAheadStream`, respectively.

Stream state structure is individual for every generator. However, each structure has a number of fields that are the same for all the generators:

```
typedef struct
{
    unsigned int Reserved1[2];
    unsigned int Reserved2[2];
    [fields specific for the given generator]
} MyStreamState;
```

The fields *Reserved1* and *Reserved2* are reserved for private needs only, and must not be modified by the user. When including specific fields into the structure, follow the rules below:

- The fields must fully describe the current state of the generator. For example, the state of a linear congruential generator can be identified by only one initial condition;
- If the generator can use both the leapfrog and the block-splitting methods, additional fields should be introduced to identify the independent streams. For example, in $LCG(a, c, m)$, apart from the initial conditions, two more fields should be specified: the value of the multiplier a^k and the value of the increment $(a^k - 1) c / (a - 1)$.

For a more detailed discussion, refer to [Knuth81], and [Gentle98]. An example of the registration procedure can be found in the respective directory of VS examples.

iBRng

```
int iMyBrng( VSLStreamStatePtr stream, int n, unsigned int r[] )
{
    int i; /* Loop variable */
    /* Generating integer random numbers */
    /* Pay attention to word size needed to
       store only random number */
    for( i = 0; i < n; i++)
    {
        r[i] = ...;
    }
    /* Update stream state */
    ...
    return errcode;
} /* iMyBrng */
```

NOTE

When using 64 and 128-bit generators, consider digit capacity to store the numbers to the random vector *r* correctly. For example, storing one 64-bit value requires two elements of *r*, the first to store the lower 32 bits and the second to store the higher 32 bits. Similarly, use 4 elements of *r* to store a 128-bit value.

sBRng

```
int sMyBrng( VSLStreamStatePtr stream, int n, float r[], float a, float b )
{
    int i; /* Loop variable */
    /* Generating float (a,b) random numbers */
    for ( i = 0; i < n; i++ )
    {
        r[i] = ...;
    }
    /* Update stream state */
    ...
    return errcode;
} /* sMyBrng */
```

dBRng

```
int dMyBrng( VSLStreamStatePtr stream, int n, double r[], double a, double b )
{
    int i;    /* Loop variable */
    /* Generating double (a,b) random numbers */
    for ( i = 0; i < n; i++ )
    {
        r[i] = ...;
    }
    /* Update stream state */
    ...
    return errcode;
} /* dMyBrng */
```

Convolution and Correlation

Intel MKL VS provides a set of routines intended to perform linear convolution and correlation transformations for single and double precision real and complex data.

For correct definition of implemented operations, see the [Mathematical Notation and Definitions](#) section.

The current implementation provides:

- Fourier algorithms for one-dimensional single and double precision real and complex data
- Fourier algorithms for multi-dimensional single and double precision real and complex data
- Direct algorithms for one-dimensional single and double precision real and complex data
- Direct algorithms for multi-dimensional single and double precision real and complex data

One-dimensional algorithms cover the following functions from the IBM* ESSL library:

SCONF, SCORF

SCOND, SCORD

SDCON, SDCOR

DDCON, DDCOR

SDDCON, SDDCOR.

Special wrappers are designed to simulate these ESSL functions. The wrappers are provided as sample sources:

```
${MKL}/examples/vslc/essl/vsl_wrappers
```

Additionally, you can browse the examples demonstrating the calculation of the ESSL functions through the wrappers:

```
${MKL}/examples/vslc/essl
```

The convolution and correlation API provides interfaces for Fortran 90 and C/89 languages. You can use the C89 interface with later versions of the C/C++.

Intel MKL provides the `mk1_vsl.h` header file. All header files are in the directory

```
${MKL}/include
```

The convolution and correlation API is implemented through task objects, or tasks. Task object is a data structure, or descriptor, which holds parameters that determine the specific convolution or correlation operation. Such parameters may be precision, type, and number of dimensions of user data, an identifier of the computation algorithm to be used, shapes of data arrays, and so on.

All the Intel MKL VS convolution and correlation routines process task objects in one way or another: either create a new task descriptor, change the parameter settings, compute mathematical results of the convolution or correlation using the stored parameters, or perform other operations. Accordingly, all routines are split into the following groups:

Task Constructors - routines that create a new task object descriptor and set up most common parameters.

Task Editors - routines that can set or modify some parameter settings in the existing task descriptor.

Task Execution Routines - compute results of the convolution or correlation operation over the actual input data, using the operation parameters held in the task descriptor.

Task Copy - routines used to make several copies of the task descriptor.

Task Destructors - routines that delete task objects and free the memory.

When the task is executed or copied for the first time, a special process runs which is called task commitment. During this process, consistency of task parameters is checked and the required work data are prepared. If the parameters are consistent, the task is tagged as committed successfully. The task remains committed until you edit its parameters. Hence, the task can be executed multiple times after a single commitment process. Since the task commitment process may include costly intermediate calculations such as preparation of Fourier transform of input data, launching the process only once can help speed up overall performance.

Naming Conventions

The names of routines, types, and constants in the convolution and correlation API are case-sensitive and can contain both lowercase and uppercase characters (`vslsConvExec`).

The names of routines have the following structure:

```
vsl[datatype]{Conv|Corr}<base name>
```

where

- `vsl` is a prefix indicating that the routine belongs to Intel® MKL Vector Statistics.
- `[datatype]` is optional. If present, the symbol specifies the type of the input and output data and can be `s` (for single precision real type), `d` (for double precision real type), `c` (for single precision complex type), or `z` (for double precision complex type).
- `Conv` or `Corr` specifies whether the routine refers to convolution or correlation task, respectively.
- `<base name>` field specifies a particular functionality that the routine is designed for, for example, `NewTask`, `DeleteTask`.

Data Types

All convolution or correlation routines use the following types for specifying data objects:

Type	Data Object
<code>VSLConvTaskPtr</code>	Pointer to a task descriptor for convolution
<code>VSLCorrTaskPtr</code>	Pointer to a task descriptor for correlation
<code>float</code>	Input/output user real data in single precision
<code>double</code>	Input/output user real data in double precision
<code>MKL_Complex8</code>	Input/output user complex data in single precision
<code>MKL_Complex16</code>	Input/output user complex data in double precision
<code>int</code>	All other data

Generic integer type (without specifying the byte size) is used for all integer data.

NOTE

The actual size of the generic integer type is platform-dependent. Before you compile your application, set an appropriate byte size for integers. See details in the 'Using the ILP64 Interface vs. LP64 Interface' section of the *Intel® MKL User's Guide*.

Parameters

Basic parameters held by the task descriptor are assigned values when the task object is created, copied, or modified by task editors. Parameters of the correlation or convolution task are initially set up by task constructors when the task object is created. Parameter changes or additional settings are made by task editors. More parameters which define location of the data being convolved need to be specified when the task execution routine is invoked.

According to how the parameters are passed or assigned values, all of them can be categorized as either explicit (directly passed as routine parameters when a task object is created or executed) or optional (assigned some default or implicit values during task construction).

The following table lists all applicable parameters used in the Intel MKL convolution and correlation API.

Convolution and Correlation Task Parameters

Name	Category	Type	Default Value Label	Description
<i>job</i>	explicit	integer	Implied by the constructor name	Specifies whether the task relates to convolution or correlation
<i>type</i>	explicit	integer	Implied by the constructor name	Specifies the type (real or complex) of the input/output data. Set to real in the current version.
<i>precision</i>	explicit	integer	Implied by the constructor name	Specifies precision (single or double) of the input/output data to be provided in arrays <i>x,y,z</i> .
<i>mode</i>	explicit	integer	None	Specifies whether the convolution/correlation computation should be done via Fourier transforms, or by a direct method, or by automatically choosing between the two. See SetMode for the list of named constants for this parameter.
<i>method</i>	optional	integer	"auto"	Hints at a particular computation method if several methods are available for the given <i>mode</i> . Setting this parameter to "auto" means that software will choose the best available method.
<i>internal_precision</i>	optional	integer	Set equal to the value of <i>precision</i>	Specifies precision of internal calculations. Can enforce double precision calculations even when input/output data are single precision. See SetInternalPrecision for the list of named constants for this parameter.
<i>dims</i>	explicit	integer	None	Specifies the rank (number of dimensions) of the user data provided in arrays <i>x,y,z</i> . Can be in the range from 1 to 7.
<i>x,y</i>	explicit	real arrays	None	Specify input data arrays. See Data Allocation for more information.

Name	Category	Type	Default Value Label	Description
<i>z</i>	explicit	real array	None	Specifies output data array. See Data Allocation for more information.
<i>xshape,</i> <i>yshape,</i> <i>zshape</i>	explicit	integer arrays	None	Define shapes of the arrays <i>x</i> , <i>y</i> , <i>z</i> . See Data Allocation for more information.
<i>xstride,</i> <i>ystride,</i> <i>zstride</i>	explicit	integer arrays	None	Define strides within arrays <i>x</i> , <i>y</i> , <i>z</i> , that is specify the physical location of the input and output data in these arrays. See Data Allocation for more information.
<i>start</i>	optional	integer array	Undefined	Defines the first element of the mathematical result that will be stored to output array <i>z</i> . See SetStart and Data Allocation for more information.
<i>decimation</i>	optional	integer array	Undefined	Defines how to thin out the mathematical result that will be stored to output array <i>z</i> . See SetDecimation and Data Allocation for more information.

Users may pass the NULL pointer instead of either or all of the parameters *xstride*, *ystride*, or *zstride* for multi-dimensional calculations. In this case, the software assumes the dense data allocation for the arrays *x*, *y*, or *z* due to the Fortran-style "by columns" representation of multi-dimensional arrays.

Task Status and Error Reporting

The task status is an integer value, which is zero if no error has been detected while processing the task, or a specific non-zero error code otherwise. Negative status values indicate errors, and positive values indicate warnings.

An error can be caused by invalid parameter values, a system fault like a memory allocation failure, or can be an internal error self-detected by the software.

Each task descriptor contains the current status of the task. When creating a task object, the constructor assigns the `VSL_STATUS_OK` status to the task. When processing the task afterwards, other routines such as editors or executors can change the task status if an error occurs and write a corresponding error code into the task status field.

Note that at the stage of creating a task or editing its parameters, the set of parameters may be inconsistent. The parameter consistency check is only performed during the task commitment operation, which is implicitly invoked before task execution or task copying. If an error is detected at this stage, task execution or task copying is terminated and the task descriptor saves the corresponding error code. Once an error occurs, any further attempts to process that task descriptor is terminated and the task keeps the same error code.

Normally, every convolution or correlation function (except `DeleteTask`) returns the status assigned to the task while performing the function operation.

The header files define symbolic names for the status codes. These names are defined as macros via the `#define` statements.

If there is no error, the `VSL_STATUS_OK` status is returned, which is defined as zero:

```
#define VSL_STATUS_OK 0
```

In case of an error, a non-zero error code is returned, which indicates the origin of the failure. The following status codes for the convolution/correlation error codes are pre-defined in the header files.

Convolution/Correlation Status Codes

Status Code	Description
VSL_CC_ERROR_NOT_IMPLEMENTED	Requested functionality is not implemented.
VSL_CC_ERROR_ALLOCATION_FAILURE	Memory allocation failure.
VSL_CC_ERROR_BAD_DESCRIPTOR	Task descriptor is corrupted.
VSL_CC_ERROR_SERVICE_FAILURE	A service function has failed.
VSL_CC_ERROR_EDIT_FAILURE	Failure while editing the task.
VSL_CC_ERROR_EDIT_PROHIBITED	You cannot edit this parameter.
VSL_CC_ERROR_COMMIT_FAILURE	Task commitment has failed.
VSL_CC_ERROR_COPY_FAILURE	Failure while copying the task.
VSL_CC_ERROR_DELETE_FAILURE	Failure while deleting the task.
VSL_CC_ERROR_BAD_ARGUMENT	Bad argument or task parameter.
VSL_CC_ERROR_JOB	Bad parameter: <i>job</i> .
SL_CC_ERROR_KIND	Bad parameter: <i>kind</i> .
VSL_CC_ERROR_MODE	Bad parameter: <i>mode</i> .
VSL_CC_ERROR_METHOD	Bad parameter: <i>method</i> .
VSL_CC_ERROR_TYPE	Bad parameter: <i>type</i> .
VSL_CC_ERROR_EXTERNAL_PRECISION	Bad parameter: <i>external_precision</i> .
VSL_CC_ERROR_INTERNAL_PRECISION	Bad parameter: <i>internal_precision</i> .
VSL_CC_ERROR_PRECISION	Incompatible external/internal precisions.
VSL_CC_ERROR_DIMS	Bad parameter: <i>dims</i> .
VSL_CC_ERROR_XSHAPE	Bad parameter: <i>xshape</i> .
VSL_CC_ERROR_YSHAPE	Bad parameter: <i>yshape</i> .
	Callback function for an abstract BRNG returns an invalid number of updated entries in a buffer, that is, < 0 or > nmax.
VSL_CC_ERROR_ZSHAPE	Bad parameter: <i>zshape</i> .
VSL_CC_ERROR_XSTRIDE	Bad parameter: <i>xstride</i> .
VSL_CC_ERROR_YSTRIDE	Bad parameter: <i>ystride</i> .
VSL_CC_ERROR_ZSTRIDE	Bad parameter: <i>zstride</i> .
VSL_CC_ERROR_X	Bad parameter: <i>x</i> .
VSL_CC_ERROR_Y	Bad parameter: <i>y</i> .
VSL_CC_ERROR_Z	Bad parameter: <i>z</i> .
VSL_CC_ERROR_START	Bad parameter: <i>start</i> .
VSL_CC_ERROR_DECIMATION	Bad parameter: <i>decimation</i> .

Status Code	Description
VSL_CC_ERROR_OTHER	Another error.

Task Constructors

Task constructors are routines intended for creating a new task descriptor and setting up basic parameters. No additional parameter adjustment is typically required and other routines can use the task object.

Intel® MKL implementation of the convolution and correlation API provides two different forms of constructors: a general form and an X-form. X-form constructors work in the same way as the general form constructors but also assign particular data to the first operand vector used in the convolution or correlation operation (stored in array *x*).

Using X-form constructors is recommended when you need to compute multiple convolutions or correlations with the same data vector held in array *x* against different vectors held in array *y*. This helps improve performance by eliminating unnecessary overhead in repeated computation of intermediate data required for the operation.

Each constructor routine has an associated one-dimensional version that provides algorithmic and computational benefits.

NOTE

If the constructor fails to create a task descriptor, it returns the `NULL` task pointer.

The Table "Task Constructors" lists available task constructors:

Task Constructors

Routine	Description
vslConvNewTask/vslCorrNewTask	Creates a new convolution or correlation task descriptor for a multidimensional case.
vslConvNewTask1D/vslCorrNewTask1D	Creates a new convolution or correlation task descriptor for a one-dimensional case.
vslConvNewTaskX/vslCorrNewTaskX	Creates a new convolution or correlation task descriptor as an X-form for a multidimensional case.
vslConvNewTaskX1D/vslCorrNewTaskX1D	Creates a new convolution or correlation task descriptor as an X-form for a one-dimensional case.

[vslConvNewTask/vslCorrNewTask](#)

Creates a new convolution or correlation task descriptor for multidimensional case.

Syntax

```
status = vslsConvNewTask(task, mode, dims, xshape, yshape, zshape);
status = vsldConvNewTask(task, mode, dims, xshape, yshape, zshape);
status = vslcConvNewTask(task, mode, dims, xshape, yshape, zshape);
status = vslzConvNewTask(task, mode, dims, xshape, yshape, zshape);
status = vslsCorrNewTask(task, mode, dims, xshape, yshape, zshape);
status = vsldCorrNewTask(task, mode, dims, xshape, yshape, zshape);
status = vslcCorrNewTask(task, mode, dims, xshape, yshape, zshape);
```

```
status = vslzCorrNewTask(task, mode, dims, xshape, yshape, zshape);
```

Input Parameters

Name	Type	Description
<i>mode</i>	const MKL_INT	Specifies whether convolution/correlation calculation must be performed by using a direct algorithm or through Fourier transform of the input data. See Table "Values of mode parameter" for a list of possible values.
<i>dims</i>	const MKL_INT	Rank of user data. Specifies number of dimensions for the input and output arrays <i>x</i> , <i>y</i> , and <i>z</i> used during the execution stage. Must be in the range from 1 to 7. The value is explicitly assigned by the constructor.
<i>xshape</i>	const int[]	Defines the shape of the input data for the source array <i>x</i> . See Data Allocation for more information.
<i>yshape</i>	const int[]	Defines the shape of the input data for the source array <i>y</i> . See Data Allocation for more information.
<i>zshape</i>	const int[]	Defines the shape of the output data to be stored in array <i>z</i> . See Data Allocation for more information.

Output Parameters

Name	Type	Description
<i>task</i>	VSLConvTaskPtr* for vslsConvNewTask, vsldConvNewTask, vslcConvNewTask, vslzConvNewTask VSLCorrTaskPtr* for vslsCorrNewTask, vsldCorrNewTask, vslcConvNewTask, vslzConvNewTask	Pointer to the task descriptor if created successfully or NULL pointer otherwise.
<i>status</i>	int	Set to VSL_STATUS_OK if the task is created successfully or set to non-zero error code otherwise.

Description

Each `vslConvNewTask/vslCorrNewTask` constructor creates a new convolution or correlation task descriptor with the user specified values for explicit parameters. The optional parameters are set to their default values (see [Table "Convolution and Correlation Task Parameters"](#)).

The parameters *xshape*, *yshape*, and *zshape* define the shapes of the input and output data provided by the arrays *x*, *y*, and *z*, respectively. Each shape parameter is an array of integers with its length equal to the value of *dims*. You explicitly assign the shape parameters when calling the constructor. If the value of the parameter *dims* is 1, then *xshape*, *yshape*, *zshape* are equal to the number of elements read from the arrays *x* and *y* or stored to the array *z*. Note that values of shape parameters may differ from physical shapes of arrays *x*, *y*, and *z* if non-trivial strides are assigned.

If the constructor fails to create a task descriptor, it returns a `NULL` task pointer.

vslConvNewTask1D/vslCorrNewTask1D

Creates a new convolution or correlation task descriptor for one-dimensional case.

Syntax

```
status = vs1sConvNewTask1D(task, mode, xshape, yshape, zshape);
status = vs1dConvNewTask1D(task, mode, xshape, yshape, zshape);
status = vs1cConvNewTask1D(task, mode, xshape, yshape, zshape);
status = vs1zConvNewTask1D(task, mode, xshape, yshape, zshape);
status = vs1sCorrNewTask1D(task, mode, xshape, yshape, zshape);
status = vs1dCorrNewTask1D(task, mode, xshape, yshape, zshape);
status = vs1cCorrNewTask1D(task, mode, xshape, yshape, zshape);
status = vs1zCorrNewTask1D(task, mode, xshape, yshape, zshape);
```

Input Parameters

Name	Type	Description
<i>mode</i>	<code>const MKL_INT</code>	Specifies whether convolution/correlation calculation must be performed by using a direct algorithm or through Fourier transform of the input data. See Table "Values of mode parameter" for a list of possible values.
<i>xshape</i>	<code>const MKL_INT</code>	Defines the length of the input data sequence for the source array <i>x</i> . See Data Allocation for more information.
<i>yshape</i>	<code>const MKL_INT</code>	Defines the length of the input data sequence for the source array <i>y</i> . See Data Allocation for more information.
<i>zshape</i>	<code>const MKL_INT</code>	Defines the length of the output data sequence to be stored in array <i>z</i> . See Data Allocation for more information.

Output Parameters

Name	Type	Description
<i>task</i>	<code>VSLConvTaskPtr*</code> for <code>vs1sConvNewTask1D</code> , <code>vs1dConvNewTask1D</code> , <code>vs1cConvNewTask1D</code> , <code>vs1zConvNewTask1D</code> <code>VSLCorrTaskPtr*</code> for <code>vs1sCorrNewTask1D</code> , <code>vs1dCorrNewTask1D</code> , <code>vs1cCorrNewTask1D</code> , <code>vs1zCorrNewTask1D</code>	Pointer to the task descriptor if created successfully or <code>NULL</code> pointer otherwise.

Name	Type	Description
<i>status</i>	int	Set to VSL_STATUS_OK if the task is created successfully or set to non-zero error code otherwise.

Description

Each `vslConvNewTask1D/vslCorrNewTask1D` constructor creates a new convolution or correlation task descriptor with the user specified values for explicit parameters. The optional parameters are set to their default values (see [Table "Convolution and Correlation Task Parameters"](#)). Unlike `vslConvNewTask/vslCorrNewTask`, these routines represent a special one-dimensional version of the constructor which assumes that the value of the parameter *dims* is 1. The parameters *xshape*, *yshape*, and *zshape* are equal to the number of elements read from the arrays *x* and *y* or stored to the array *z*. You explicitly assign the shape parameters when calling the constructor.

vslConvNewTaskX/vslCorrNewTaskX

Creates a new convolution or correlation task descriptor for multidimensional case and assigns source data to the first operand vector.

Syntax

```
status = vs1sConvNewTaskX(task, mode, dims, xshape, yshape, zshape, x, xstride);
status = vs1dConvNewTaskX(task, mode, dims, xshape, yshape, zshape, x, xstride);
status = vs1cConvNewTaskX(task, mode, dims, xshape, yshape, zshape, x, xstride);
status = vs1zConvNewTaskX(task, mode, dims, xshape, yshape, zshape, x, xstride);
status = vs1sCorrNewTaskX(task, mode, dims, xshape, yshape, zshape, x, xstride);
status = vs1dCorrNewTaskX(task, mode, dims, xshape, yshape, zshape, x, xstride);
status = vs1cCorrNewTaskX(task, mode, dims, xshape, yshape, zshape, x, xstride);
status = vs1zCorrNewTaskX(task, mode, dims, xshape, yshape, zshape, x, xstride);
```

<i>zshape</i>	<code>const int[]</code>	Defines the shape of the output data to be stored in array <i>z</i> . See Data Allocation for more information.
<i>x</i>	<code>const float[]</code> for real data in single precision flavors, <code>const double[]</code> for real data in double precision flavors, <code>const MKL_Complex8[]</code> for complex data in single precision flavors, <code>const MKL_Complex16[]</code> for complex data in double precision flavors	Pointer to the array containing input data for the first operand vector. See Data Allocation for more information.
<i>xstride</i>	<code>const int[]</code>	Strides for input data in the array <i>x</i> .

Output Parameters

Name	Type	Description
<i>task</i>	VSLConvTaskPtr* for vslsConvNewTaskX, vsldConvNewTaskX, vslcConvNewTaskX, vslzConvNewTaskX VSLCorrTaskPtr* for vslsCorrNewTaskX, vsldCorrNewTaskX, vslcCorrNewTaskX, vslzCorrNewTaskX	Pointer to the task descriptor if created successfully or NULL pointer otherwise.
<i>status</i>	<code>int</code>	Set to VSL_STATUS_OK if the task is created successfully or set to non-zero error code otherwise.

Description

Each `vslConvNewTaskX/vslCorrNewTaskX` constructor creates a new convolution or correlation task descriptor with the user specified values for explicit parameters. The optional parameters are set to their default values (see [Table "Convolution and Correlation Task Parameters"](#)).

Unlike `vslConvNewTask/vslCorrNewTask`, these routines represent the so called X-form version of the constructor, which means that in addition to creating the task descriptor they assign particular data to the first operand vector in array *x* used in convolution or correlation operation. The task descriptor created by the `vslConvNewTaskX/vslCorrNewTaskX` constructor keeps the pointer to the array *x* all the time, that is, until the task object is deleted by one of the destructor routines (see [vslConvDeleteTask/vslCorrDeleteTask](#)).

Using this form of constructors is recommended when you need to compute multiple convolutions or correlations with the same data vector in array *x* against different vectors in array *y*. This helps improve performance by eliminating unnecessary overhead in repeated computation of intermediate data required for the operation.

The parameters *xshape*, *yshape*, and *zshape* define the shapes of the input and output data provided by the arrays *x*, *y*, and *z*, respectively. Each shape parameter is an array of integers with its length equal to the value of *dims*. You explicitly assign the shape parameters when calling the constructor. If the value of the parameter *dims* is 1, then *xshape*, *yshape*, and *zshape* are equal to the number of elements read from the arrays *x* and *y* or stored to the array *z*. Note that values of shape parameters may differ from physical shapes of arrays *x*, *y*, and *z* if non-trivial strides are assigned.

The stride parameter *xstride* specifies the physical location of the input data in the array *x*. In a one-dimensional case, stride is an interval between locations of consecutive elements of the array. For example, if the value of the parameter *xstride* is *s*, then only every *s*th element of the array *x* will be used to form the input sequence. The stride value must be positive or negative but not zero.

vslConvNewTaskX1D/vslCorrNewTaskX1D

Creates a new convolution or correlation task descriptor for one-dimensional case and assigns source data to the first operand vector.

Syntax

```
status = vslsConvNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
status = vsldConvNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
status = vslcConvNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
status = vslzConvNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
status = vslsCorrNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
status = vsldCorrNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
status = vslcCorrNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
status = vslzCorrNewTaskX1D(task, mode, xshape, yshape, zshape, x, xstride);
```

<i>xstride</i>	const MKL_INT	Stride for input data sequence in the arrayx.

Output Parameters

Name	Type	Description
<i>task</i>	VSLConvTaskPtr* for vs1sConvNewTaskX1D, vs1dConvNewTaskX1D, vs1cConvNewTaskX1D, vs1zConvNewTaskX1D VSLCorrTaskPtr* for vs1sCorrNewTaskX1D, vs1dCorrNewTaskX1D, vs1cCorrNewTaskX1D, vs1zCorrNewTaskX1D	Pointer to the task descriptor if created successfully or NULL pointer otherwise.
<i>status</i>	int	Set to VSL_STATUS_OK if the task is created successfully or set to non-zero error code otherwise.

Description

Each `vs1ConvNewTaskX1D/vs1CorrNewTaskX1D` constructor creates a new convolution or correlation task descriptor with the user specified values for explicit parameters. The optional parameters are set to their default values (see [Table "Convolution and Correlation Task Parameters"](#)).

These routines represent a special one-dimensional version of the so called X-form of the constructor. This assumes that the value of the parameter `dims` is 1 and that in addition to creating the task descriptor, constructor routines assign particular data to the first operand vector in array `x` used in convolution or correlation operation. The task descriptor created by the `vs1ConvNewTaskX1D/vs1CorrNewTaskX1D` constructor keeps the pointer to the array `x` all the time, that is, until the task object is deleted by one of the destructor routines (see [vs1ConvDeleteTask/vs1CorrDeleteTask](#)).

Using this form of constructors is recommended when you need to compute multiple convolutions or correlations with the same data vector in array `x` against different vectors in array `y`. This helps improve performance by eliminating unnecessary overhead in repeated computation of intermediate data required for the operation.

The parameters `xshape`, `yshape`, and `zshape` are equal to the number of elements read from the arrays `x` and `y` or stored to the array `z`. You explicitly assign the shape parameters when calling the constructor.

The [stride parameters](#) `xstride` specifies the physical location of the input data in the array `x` and is an interval between locations of consecutive elements of the array. For example, if the value of the parameter `xstride` is `s`, then only every s^{th} element of the array `x` will be used to form the input sequence. The stride value must be positive or negative but not zero.

Task Editors

Task editors in convolution and correlation API of Intel MKL are routines intended for setting up or changing the following task parameters (see [Table "Convolution and Correlation Task Parameters"](#)):

- *mode*
- *internal_precision*
- *start*
- *decimation*

For setting up or changing each of the above parameters, a separate routine exists.

NOTE

Fields of the task descriptor structure are accessible only through the set of task editor routines provided with the software.

The work data computed during the last commitment process may become invalid with respect to new parameter settings. That is why after applying any of the editor routines to change the task descriptor settings, the task loses its commitment status and goes through the full commitment process again during the next execution or copy operation. For more information on task commitment, see the [Introduction to Convolution and Correlation](#).

[Table "Task Editors"](#) lists available task editors.

Task Editors

Routine	Description
vslConvSetMode/vslCorrSetMode	Changes the value of the parameter <i>mode</i> for the operation of convolution or correlation.
vslConvSetInternalPrecision/vslCorrSetInternalPrecision	Changes the value of the parameter <i>internal_precision</i> for the operation of convolution or correlation.
vslConvSetStart/vslCorrSetStart	Sets the value of the parameter <i>start</i> for the operation of convolution or correlation.
vslConvSetDecimation/vslCorrSetDecimation	Sets the value of the parameter <i>decimation</i> for the operation of convolution or correlation.

NOTE

You can use the `NULL` task pointer in calls to editor routines. In this case, the routine is terminated and no system crash occurs.

[vslConvSetMode/vslCorrSetMode](#)

*Changes the value of the parameter *mode* in the convolution or correlation task descriptor.*

Syntax

```
status = vslConvSetMode(task, newmode);
```

```
status = vslCorrSetMode(task, newmode);
```

Include Files

- `mkh.h`

Input Parameters

Name	Type	Description
<i>task</i>	VSLConvTaskPtr for vslConvSetMode VSLCorrTaskPtr for vslCorrSetMode	Pointer to the task descriptor.
<i>newmode</i>	const MKL_INT	New value of the parameter <i>mode</i> .

Output Parameters

Name	Type	Description
<i>status</i>	int	Current status of the task.

Description

This function is declared in `mk1_vsl_functions.h`.

The function routine changes the value of the parameter *mode* for the operation of convolution or correlation. This parameter defines whether the computation should be done via Fourier transforms of the input/output data or using a direct algorithm. Initial value for *mode* is assigned by a task constructor.

Predefined values for the *mode* parameter are as follows:

Values of *mode* parameter

Value	Purpose
VSL_CONV_MODE_FFT	Compute convolution by using fast Fourier transform.
VSL_CORR_MODE_FFT	Compute correlation by using fast Fourier transform.
VSL_CONV_MODE_DIRECT	Compute convolution directly.
VSL_CORR_MODE_DIRECT	Compute correlation directly.
VSL_CONV_MODE_AUTO	Automatically choose direct or Fourier mode for convolution.
VSL_CORR_MODE_AUTO	Automatically choose direct or Fourier mode for correlation.

vslConvSetInternalPrecision/vslCorrSetInternalPrecision

*Changes the value of the parameter *internal_precision* in the convolution or correlation task descriptor.*

Syntax

```
status = vslConvSetInternalPrecision(task, precision);
status = vslCorrSetInternalPrecision(task, precision);
```

Include Files

- `mk1.h`

Input Parameters

Name	Type	Description
<i>task</i>	VSLConvTaskPtr for vslConvSetInternalPrecision VSLCorrTaskPtr for vslCorrSetInternalPrecision	Pointer to the task descriptor.
<i>precision</i>	const MKL_INT	New value of the parameter <i>internal_precision</i> .

Output Parameters

Name	Type	Description
<i>status</i>	int	Current status of the task.

Description

The `vslConvSetInternalPrecision/vslCorrSetInternalPrecision` routine changes the value of the parameter *internal_precision* for the operation of convolution or correlation. This parameter defines whether the internal computations of the convolution or correlation result should be done in single or double precision. Initial value for *internal_precision* is assigned by a task constructor and set to either "single" or "double" according to the particular flavor of the constructor used.

Changing the *internal_precision* can be useful if the default setting of this parameter was "single" but you want to calculate the result with double precision even if input and output data are represented in single precision.

Predefined values for the *internal_precision* input parameter are as follows:

Values of *internal_precision* Parameter

Value	Purpose
VSL_CONV_PRECISION_SINGLE	Compute convolution with single precision.
VSL_CORR_PRECISION_SINGLE	Compute correlation with single precision.
VSL_CONV_PRECISION_DOUBLE	Compute convolution with double precision.
VSL_CORR_PRECISION_DOUBLE	Compute correlation with double precision.

vslConvSetStart/vslCorrSetStart

Changes the value of the parameter start in the convolution or correlation task descriptor.

Syntax

```
status = vslConvSetStart(task, start);
status = vslCorrSetStart(task, start);
```

Include Files

- `mkh.h`

Input Parameters

Name	Type	Description
<i>task</i>	VSLConvTaskPtr for vslConvSetStart VSLCorrTaskPtr for vslCorrSetStart	Pointer to the task descriptor.
<i>start</i>	const int[]	New value of the parameter <i>start</i> .

Output Parameters

Name	Type	Description
<i>status</i>	int	Current status of the task.

Description

The `vslConvSetStart/vslCorrSetStart` routine sets the value of the parameter *start* for the operation of convolution or correlation. In a one-dimensional case, this parameter points to the first element in the mathematical result that should be stored in the output array. In a multidimensional case, *start* is an array of indices and its length is equal to the number of dimensions specified by the parameter *dims*. For more information about the definition and effect of this parameter, see [Data Allocation](#).

During the initial task descriptor construction, the default value for *start* is undefined and this parameter is not used. Therefore the only way to set and use the *start* parameter is via assigning it some value by one of the `vslConvSetStart/vslCorrSetStart` routines.

vslConvSetDecimation/vslCorrSetDecimation

Changes the value of the parameter decimation in the convolution or correlation task descriptor.

Syntax

```
status = vslConvSetDecimation(task, decimation);
status = vslCorrSetDecimation(task, decimation);
```

Include Files

- `mkl.h`

Input Parameters

Name	Type	Description
<i>task</i>	VSLConvTaskPtr for vslConvSetDecimation VSLCorrTaskPtr for vslCorrSetDecimation	Pointer to the task descriptor.
<i>decimation</i> <i>n</i>	const int[]	New value of the parameter <i>decimation</i> .

Output Parameters

Name	Type	Description
<i>status</i>	int	Current status of the task.

Description

The routine sets the value of the parameter *decimation* for the operation of convolution or correlation. This parameter determines how to thin out the mathematical result of convolution or correlation before writing it into the output data array. For example, in a one-dimensional case, if *decimation* = $d > 1$, only every d -th element of the mathematical result is written to the output array *z*. In a multidimensional case, *decimation* is an array of indices and its length is equal to the number of dimensions specified by the parameter *dims*. For more information about the definition and effect of this parameter, see [Data Allocation](#).

During the initial task descriptor construction, the default value for *decimation* is undefined and this parameter is not used. Therefore the only way to set and use the *decimation* parameter is via assigning it some value by one of the `vslSetDecimation` routines.

Task Execution Routines

Task execution routines compute convolution or correlation results based on parameters held by the task descriptor and on the user data supplied for input vectors.

After you create and adjust a task, you can execute it multiple times by applying to different input/output data of the same type, precision, and shape.

Intel MKL provides the following forms of convolution/correlation execution routines:

- **General form** executors that use the task descriptor created by the general form constructor and expect to get two source data arrays *x* and *y* on input
- **X-form** executors that use the task descriptor created by the X-form constructor and expect to get only one source data array *y* on input because the first array *x* has been already specified on the construction stage

When the task is executed for the first time, the execution routine includes a task commitment operation, which involves two basic steps: parameters consistency check and preparation of auxiliary data (for example, this might be the calculation of Fourier transform for input data).

Each execution routine has an associated one-dimensional version that provides algorithmic and computational benefits.

NOTE

You can use the `NULL` task pointer in calls to execution routines. In this case, the routine is terminated and no system crash occurs.

If the task is executed successfully, the execution routine returns the zero status code. If an error is detected, the execution routine returns an error code which signals that a specific error has occurred. In particular, an error status code is returned in the following cases:

- if the task pointer is `NULL`
- if the task descriptor is corrupted
- if calculation has failed for some other reason.

NOTE

Intel® MKL does not control floating-point errors, like overflow or gradual underflow, or operations with NaNs, etc.

If an error occurs, the task descriptor stores the error code.

The table below lists all task execution routines.

Task Execution Routines

Routine	Description
vslConvExec/vslCorrExec	Computes convolution or correlation for a multidimensional case.
vslConvExec1D/vslCorrExec1D	Computes convolution or correlation for a one-dimensional case.
vslConvExecX/vslCorrExecX	Computes convolution or correlation as X-form for a multidimensional case.
vslConvExecX1D/vslCorrExecX1D	Computes convolution or correlation as X-form for a one-dimensional case.

[vslConvExec/vslCorrExec](#)

Computes convolution or correlation for multidimensional case.

Syntax

```
status = vslsConvExec(task, x, xstride, y, ystride, z, zstride);
status = vsldConvExec(task, x, xstride, y, ystride, z, zstride);
status = vslcConvExec(task, x, xstride, y, ystride, z, zstride);
status = vslzConvExec(task, x, xstride, y, ystride, z, zstride);
status = vslsCorrExec(task, x, xstride, y, ystride, z, zstride);
status = vsldCorrExec(task, x, xstride, y, ystride, z, zstride);
status = vslcCorrExec(task, x, xstride, y, ystride, z, zstride);
status = vslzCorrExec(task, x, xstride, y, ystride, z, zstride);
```

Include Files

- `mkl.h`

Input Parameters

Name	Type	Description
<code>task</code>	VSLConvTaskPtr for vslsConvExec, vsldConvExec, vslcConvExec, vslzConvExec VSLCorrTaskPtr for vslsCorrExec, vsldCorrExec, vslcCorrExec, vslzCorrExec	Pointer to the task descriptor
<code>x, y</code>	const float[] for vslsConvExec and vslsCorrExec, const double[] for vsldConvExec and vsldCorrExec,	Pointers to arrays containing input data. See Data Allocation for more information.

Name	Type	Description
	const MKL_Complex8[] for vslcConvExec and vslcCorrExec, const MKL_Complex16[] for vslzConvExec and vslzCorrExec	
<i>xstride</i> , <i>ystride</i> , <i>zstride</i>	const int[]	Strides for input and output data. For more information, see stride parameters .

Output Parameters

Name	Type	Description
<i>z</i>	const float[] for vslsConvExec and vslsCorrExec, const double[] for vsldConvExec and vsldCorrExec, const MKL_Complex8[] for vslcConvExec and vslcCorrExec, const MKL_Complex16[] for vslzConvExec and vslzCorrExec	Pointer to the array that stores output data. See Data Allocation for more information.
<i>status</i>	int	Set to VSL_STATUS_OK if the task is executed successfully or set to non-zero error code otherwise.

Description

Each of the `vslConvExec/vslCorrExec` routines computes convolution or correlation of the data provided by the arrays *x* and *y* and then stores the results in the array *z*. Parameters of the operation are read from the task descriptor created previously by a corresponding `vslConvNewTask/vslCorrNewTask` constructor and pointed to by *task*. If *task* is NULL, no operation is done.

The stride parameters *xstride*, *ystride*, and *zstride* specify the physical location of the input and output data in the arrays *x*, *y*, and *z*, respectively. In a one-dimensional case, stride is an interval between locations of consecutive elements of the array. For example, if the value of the parameter *zstride* is *s*, then only every *s*th element of the array *z* will be used to store the output data. The stride value must be positive or negative but not zero.

vslConvExec1D/vslCorrExec1D

Computes convolution or correlation for one-dimensional case.

Syntax

```
status = vslsConvExec1D(task, x, xstride, y, ystride, z, zstride);
status = vsldConvExec1D(task, x, xstride, y, ystride, z, zstride);
```

```

status = vslcConvExec1D(task, x, xstride, y, ystride, z, zstride);
status = vslzConvExec1D(task, x, xstride, y, ystride, z, zstride);
status = vslsCorrExec1D(task, x, xstride, y, ystride, z, zstride);
status = vsldCorrExec1D(task, x, xstride, y, ystride, z, zstride);
status = vslcCorrExec1D(task, x, xstride, y, ystride, z, zstride);
status = vslzCorrExec1D(task, x, xstride, y, ystride, z, zstride);

```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>task</i>	VSLConvTaskPtr for vslsConvExec1D, vsldConvExec1D, vslcConvExec1D, vslzConvExec1D VSLCorrTaskPtr for vslsCorrExec1D, vsldCorrExec1D, vslcCorrExec1D, vslzCorrExec1D	Pointer to the task descriptor.
<i>x, y</i>	const float[] for vslsConvExec1D and vslsCorrExec1D, const double[] for vsldConvExec1D and vsldCorrExec1D, const MKL_Complex8[] for vslcConvExec1D and vslcCorrExec1D, const MKL_Complex16[] for vslzConvExec1D and vslzCorrExec1D	Pointers to arrays containing input data. See Data Allocation for more information.
<i>xstride,</i> <i>ystride,</i> <i>zstride</i>	const MKL_INT	Strides for input and output data. For more information, see stride parameters .

Output Parameters

Name	Type	Description
<i>z</i>	const float[] for vslsConvExec1D and vslsCorrExec1D,	Pointer to the array that stores output data. See Data Allocation for more information.

Name	Type	Description
	<pre>const double[] for vsldConvExec1D and vsldCorrExec1D, const MKL_Complex8[] for vslcConvExec1D and vslcCorrExec1D, const MKL_Complex16[] for vslzConvExec1D and vslzCorrExec1D</pre>	
<i>status</i>	int	Set to VSL_STATUS_OK if the task is executed successfully or set to non-zero error code otherwise.

Description

Each of the `vslConvExec1D/vslCorrExec1D` routines computes convolution or correlation of the data provided by the arrays *x* and *y* and then stores the results in the array *z*. These routines represent a special one-dimensional version of the operation, assuming that the value of the parameter *dims* is 1. Using this version of execution routines can help speed up performance in case of one-dimensional data.

Parameters of the operation are read from the task descriptor created previously by a corresponding `vslConvNewTask1D/vslCorrNewTask1D` constructor and pointed to by *task*. If *task* is NULL, no operation is done.

vslConvExecX/vslCorrExecX

Computes convolution or correlation for multidimensional case with the fixed first operand vector.

Syntax

```
status = vslsConvExecX(task, y, ystride, z, zstride);
status = vsldConvExecX(task, y, ystride, z, zstride);
status = vslcConvExecX(task, y, ystride, z, zstride);
status = vslzConvExecX(task, y, ystride, z, zstride);
status = vslsCorrExecX(task, y, ystride, z, zstride);
status = vslcCorrExecX(task, y, ystride, z, zstride);
status = vslzCorrExecX(task, y, ystride, z, zstride);
status = vsldCorrExecX(task, y, ystride, z, zstride);
```

Include Files

- `mkl.h`

Input Parameters

Name	Type	Description
<i>task</i>	VSLConvTaskPtr for vslsConvExecX, vsldConvExecX, vslcConvExecX, vslzConvExecX VSLCorrTaskPtr for vslsCorrExecX, vsldCorrExecX, vslcCorrExecX, vslzCorrExecX	Pointer to the task descriptor.
<i>x ,y</i>	const float[] for vslsConvExecX and vslsCorrExecX, const double[] for vsldConvExecX and vsldCorrExecX, const MKL_Complex8[] for vslcConvExecX and vslcCorrExecX, const MKL_Complex16[] for vslzConvExecX and vslzCorrExecX	Pointer to array containing input data (for the second operand vector). See Data Allocation for more information.
<i>ystride ,z stride</i>	const int[]	Strides for input and output data. For more information, see stride parameters .

Output Parameters

Name	Type	Description
<i>z</i>	const float[] for vslsConvExecX and vslsCorrExecX, const double[] for vsldConvExecX and vsldCorrExecX, const MKL_Complex8[] for vslcConvExecX and vslcCorrExecX, const MKL_Complex16[] for vslzConvExecX and vslzCorrExecX	Pointer to the array that stores output data. See Data Allocation for more information.
<i>status</i>	int	Set to VSL_STATUS_OK if the task is executed successfully or set to non-zero error code otherwise.

Description

Each of the `vslConvExecX/vslCorrExecX` routines computes convolution or correlation of the data provided by the arrays `x` and `y` and then stores the results in the array `z`. These routines represent a special version of the operation, which assumes that the first operand vector was set on the task construction stage and the task object keeps the pointer to the array `x`.

Parameters of the operation are read from the task descriptor created previously by a corresponding `vslConvNewTaskX/vslCorrNewTaskX` constructor and pointed to by `task`. If `task` is `NULL`, no operation is done.

Using this form of execution routines is recommended when you need to compute multiple convolutions or correlations with the same data vector in array `x` against different vectors in array `y`. This helps improve performance by eliminating unnecessary overhead in repeated computation of intermediate data required for the operation.

vslConvExecX1D/vslCorrExecX1D

Computes convolution or correlation for one-dimensional case with the fixed first operand vector.

Syntax

```
status = vslsConvExecX1D(task, y, ystride, z, zstride);
status = vsldConvExecX1D(task, y, ystride, z, zstride);
status = vslcConvExecX1D(task, y, ystride, z, zstride);
status = vslzConvExecX1D(task, y, ystride, z, zstride);
status = vslsCorrExecX1D(task, y, ystride, z, zstride);
status = vslcCorrExecX1D(task, y, ystride, z, zstride);
status = vslzCorrExecX1D(task, y, ystride, z, zstride);
status = vsldCorrExecX1D(task, y, ystride, z, zstride);
```

Include Files

- `mkl.h`

Input Parameters

Name	Type	Description
<code>task</code>	VSLConvTaskPtr for vslsConvExecX1D, vsldConvExecX1D, vslcConvExecX1D, vslzConvExecX1D VSLCorrTaskPtr for vslsCorrExecX1D, vsldCorrExecX1D, vslcCorrExecX1D, vslzCorrExecX1D	Pointer to the task descriptor.
<code>x, y</code>	const float[] for vslsConvExecX1D and vslsCorrExecX1D,	Pointer to array containing input data (for the second operand vector). See Data Allocation for more information.

Name	Type	Description
	const double[] for vsldConvExecX1D and vsldCorrExecX1D, const MKL_Complex8[] for vslcConvExecX1D and vslcCorrExecX1D, const MKL_Complex16[] for vslzConvExecX1D and vslzCorrExecX1D	
<i>ystride</i> , <i>zstride</i>	const MKL_INT	Strides for input and output data. For more information, see stride parameters .

Output Parameters

Name	Type	Description
<i>z</i>	const float[] for vslsConvExecX1D and vslsCorrExecX1D, const double[] for vsldConvExecX1D and vsldCorrExecX1D, const MKL_Complex8[] for vslcConvExecX1D and vslcCorrExecX1D, const MKL_Complex16[] for vslzConvExecX1D and vslzCorrExecX1D	Pointer to the array that stores output data. See Data Allocation for more information.
<i>status</i>	int	Set to VSL_STATUS_OK if the task is executed successfully or set to non-zero error code otherwise.

Description

Each of the `vslConvExecX1D/vslCorrExecX1D` routines computes convolution or correlation of one-dimensional (assuming that `dims = 1`) data provided by the arrays `x` and `y` and then stores the results in the array `z`. These routines represent a special version of the operation, which expects that the first operand vector was set on the task construction stage.

Parameters of the operation are read from the task descriptor created previously by a corresponding `vslConvNewTaskX1D/vslCorrNewTaskX1D` constructor and pointed to by `task`. If `task` is NULL, no operation is done.

Using this form of execution routines is recommended when you need to compute multiple one-dimensional convolutions or correlations with the same data vector in array `x` against different vectors in array `y`. This helps improve performance by eliminating unnecessary overhead in repeated computation of intermediate data required for the operation.

Task Destructors

Task destructors are routines designed for deleting task objects and deallocating memory.

vslConvDeleteTask/vslCorrDeleteTask

Destroys the task object and frees the memory.

Syntax

```
errcode = vslConvDeleteTask(task);
```

```
errcode = vslCorrDeleteTask(task);
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>task</i>	VSLConvTaskPtr* for vslConvDeleteTask VSLCorrTaskPtr* for vslCorrDeleteTask	Pointer to the task descriptor.

Output Parameters

Name	Type	Description
<i>errcode</i>	int	Contains 0 if the task object is deleted successfully. Contains an error code if an error occurred.

Description

The `vslConvDeleteTask/vslCorrvDeleteTask` routine deletes the task descriptor object and frees any working memory and the memory allocated for the data structure. The task pointer is set to `NULL`.

Note that if the `vslConvDeleteTask/vslCorrvDeleteTask` routine does not delete the task successfully, the routine returns an error code. This error code has no relation to the task status code and does not change it.

NOTE

You can use the `NULL` task pointer in calls to destructor routines. In this case, the routine terminates with no system crash.

Task Copy

The routines are designed for copying convolution and correlation task descriptors.

vslConvCopyTask/vslCorrCopyTask

Copies a descriptor for convolution or correlation task.

Syntax

```
status = vslConvCopyTask(newtask, srctask);
```

```
status = vslCorrCopyTask(newtask, srctask);
```

Include Files

- `mkl.h`

Input Parameters

Name	Type	Description
<i>srctask</i>	const <code>VSLConvTaskPtr</code> for <code>vslConvCopyTask</code> const <code>VSLCorrTaskPtr</code> for <code>vslCorrCopyTask</code>	Pointer to the source task descriptor.

Output Parameters

Name	Type	Description
<i>newtask</i>	<code>VSLConvTaskPtr*</code> for <code>vslConvCopyTask</code> <code>VSLCorrTaskPtr*</code> for <code>vslCorrCopyTask</code>	Pointer to the new task descriptor.
<i>status</i>	<code>int</code>	Current status of the source task.

Description

If a task object *srctask* already exists, you can use an appropriate `vslConvCopyTask/vslCorrCopyTask` routine to make its copy in *newtask*. After the copy operation, both source and new task objects will become committed (see [Introduction to Convolution and Correlation](#) for information about task commitment). If the source task was not previously committed, the commitment operation for this task is implicitly invoked before copying starts. If an error occurs during source task commitment, the task stores the error code in the status field. If an error occurs during copy operation, the routine returns a `NULL` pointer instead of a reference to a new task object.

Usage Examples

This section demonstrates how you can use the Intel MKL routines to perform some common convolution and correlation operations both for single-threaded and multithreaded calculations. The following two sample functions `scond1` and `sconf1` simulate the convolution and correlation functions `SCOND` and `SCONF` found in IBM ESSL* library. The functions assume single-threaded calculations and can be used with C or C++ compilers.

Function scnd1 for Single-Threaded Calculations

```
#include "mkl_vsl.h"

int scnd1(
    float h[], int inch,
    float x[], int incx,
    float y[], int incy,
    int nh, int nx, int iy0, int ny)
{
    int status;
    VSLConvTaskPtr task;
    vslsConvNewTask1D(&task, VSL_CONV_MODE_DIRECT, nh, nx, ny);
    vslConvSetStart(task, &iy0);
    status = vslsConvExec1D(task, h, inch, x, incx, y, incy);
    vslConvDeleteTask(&task);
    return status;
}
```

Function `sconf1` for Single-Threaded Calculations

```
#include "mkl_vsl.h"

int sconf1(
    int init,
    float h[], int inclh,
    float x[], int inclx, int inc2x,
    float y[], int incly, int inc2y,
    int nh, int nx, int m, int iy0, int ny,
    void* aux1, int naux1, void* aux2, int naux2)
{
    int status;

    /* assume that aux1!=0 and naux1 is big enough */
    VSLConvTaskPtr* task = (VSLConvTaskPtr*)aux1;

    if (init != 0)
        /* initialization: */
        status = vslsConvNewTaskX1D(task, VSL_CONV_MODE_FFT,
            nh, nx, ny, h, inclh);

    if (init == 0) {
        /* calculations: */
        int i;
        vslConvSetStart(*task, &iy0);

        for (i=0; i<m; i++) {
            float* xi = &x[inc2x * i];
            float* yi = &y[inc2y * i];

            /* task is implicitly committed at i==0 */
            status = vslsConvExecX1D(*task, xi, inclx, yi, incly);
        };

        vslConvDeleteTask(task);

        return status;
    }
}
```

Using Multiple Threads

For functions such as `sconf1` described in the previous example, parallel calculations may be more preferable instead of cycling. If $m > 1$, you can use multiple threads for invoking the task execution against different data sequences. For such cases, use task copy routines to create m copies of the task object before the calculations stage and then run these copies with different threads. Ensure that you make all necessary parameter adjustments for the task (using [Task Editors](#)) before copying it.

The sample code in this case may look as follows:

```
if (init == 0) {
    int i, status, ss[M];
    VSLConvTaskPtr tasks[M];
    /* assume that M is big enough */
    . . .
    vslConvSetStart(*task, &iy0);
    . . .
    for (i=0; i<m; i++)
        /* implicit commitment at i==0 */
        vslConvCopyTask(&tasks[i],*task);
    . . .
}
```

Then, m threads may be started to execute different copies of the task:

```
. . .
float* xi = &x[inc2x * i];
float* yi = &y[inc2y * i];
ss[i]=vslsConvExec1D(tasks[i], xi,inc1x, yi,inc1y);
. . .
}
```

And finally, after all threads have finished the calculations, overall status should be collected from all task objects. The following code signals the first error found, if any:

```
. . .
for (i=0; i<m; i++) {
    status = ss[i];
    if (status != 0) /* 0 means "OK" */
        break;
};
return status;
}; /* end if init==0 */
```

Execution routines modify the task internal state (fields of the task structure). Such modifications may conflict with each other if different threads work with the same task object simultaneously. That is why different threads must use different copies of the task.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Mathematical Notation and Definitions

The following notation is necessary to explain the underlying mathematical definitions used in the text:

$\mathbf{R} = (-\infty, +\infty)$	The set of real numbers.
$\mathbf{Z} = \{0, \pm 1, \pm 2, \dots\}$	The set of integer numbers.
$\mathbf{Z}^N = \mathbf{Z} \times \dots \times \mathbf{Z}$	The set of N-dimensional series of integer numbers.
$p = (p_1, \dots, p_N) \in \mathbf{Z}^N$	N-dimensional series of integers.
$u: \mathbf{Z}^N \rightarrow \mathbf{R}$	Function u with arguments from $\mathbf{Z}^N$ and values from $\mathbf{R}$.
$u(p) = u(p_1, \dots, p_N)$	The value of the function u for the argument $(p_1, \dots, p_N)$.
$w = u * v$	Function w is the convolution of the functions u, v .
$w = u \bullet v$	Function w is the correlation of the functions u, v .

Given series $p, q \in \mathbf{Z}^N$:

- series $r = p + q$ is defined as $r^n = p^n + q^n$ for every $n=1, \dots, N$
- series $r = p - q$ is defined as $r^n = p^n - q^n$ for every $n=1, \dots, N$
- series $r = \sup\{p, q\}$ is defined as $r^n = \max\{p^n, q^n\}$ for every $n=1, \dots, N$
- series $r = \inf\{p, q\}$ is defined as $r^n = \min\{p^n, q^n\}$ for every $n=1, \dots, N$
- inequality $p \leq q$ means that $p^n \leq q^n$ for every $n=1, \dots, N$.

A function $u(p)$ is called a finite function if there exist series $p^{\min}, p^{\max} \in \mathbf{Z}^N$ such that:

$$u(p) \neq 0$$

implies

$$p^{\min} \leq p \leq p^{\max}.$$

Operations of convolution and correlation are only defined for finite functions.

Consider functions u, v and series $p^{\min}, p^{\max}, q^{\min}, q^{\max} \in \mathbf{Z}^N$ such that:

$$u(p) \neq 0 \text{ implies } p^{\min} \leq p \leq p^{\max}.$$

$$v(q) \neq 0 \text{ implies } q^{\min} \leq q \leq q^{\max}.$$

Definitions of linear correlation and linear convolution for functions u and v are given below.

Linear Convolution

If function $w = u * v$ is the convolution of u and v , then:

$$w(r) \neq 0 \text{ implies } \mathbf{R}^{\min} \leq r \leq \mathbf{R}^{\max},$$

$$\text{where } \mathbf{R}^{\min} = p^{\min} + q^{\min} \text{ and } \mathbf{R}^{\max} = p^{\max} + q^{\max}.$$

If $\mathbf{R}^{\min} \leq r \leq \mathbf{R}^{\max}$, then:

$$w(r) = \sum u(t) \cdot v(r-t) \text{ is the sum for all } t \in \mathbf{Z}^N \text{ such that } \mathbf{T}^{\min} \leq t \leq \mathbf{T}^{\max},$$

$$\text{where } \mathbf{T}^{\min} = \sup\{p^{\min}, r - q^{\max}\} \text{ and } \mathbf{T}^{\max} = \inf\{p^{\max}, r - q^{\min}\}.$$

Linear Correlation

If function $w = u \bullet v$ is the correlation of u and v , then:

$$w(r) \neq 0 \text{ implies } \mathbf{R}^{\min} \leq r \leq \mathbf{R}^{\max},$$

$$\text{where } \mathbf{R}^{\min} = q^{\min} - p^{\max} \text{ and } \mathbf{R}^{\max} = q^{\max} - p^{\min}.$$

If $\mathbf{R}^{\min} \leq r \leq \mathbf{R}^{\max}$, then:

$w(r) = \sum u(t) \cdot v(r+t)$ is the sum for all $t \in \mathbf{Z}^N$ such that $\mathbf{T}^{\min} \leq t \leq \mathbf{T}^{\max}$,
where $\mathbf{T}^{\min} = \sup\{P^{\min}, Q^{\min}-r\}$ and $\mathbf{T}^{\max} = \inf\{P^{\max}, Q^{\max}-r\}$.

Representation of the functions u , v , w as the input/output data for the Intel MKL convolution and correlation functions is described in the [Data Allocation](#) section below.

Data Allocation

This section explains the relation between:

- mathematical finite functions u , v , w introduced in the section [Mathematical Notation and Definitions](#);
- multi-dimensional input and output data vectors representing the functions u , v , w ;
- arrays u , v , w used to store the input and output data vectors in computer memory

The convolution and correlation routine parameters that determine the allocation of input and output data are the following:

- Data arrays x , y , z
- Shape arrays $xshape$, $yshape$, $zshape$
- Strides within arrays $xstride$, $ystride$, $zstride$
- Parameters $start$, $decimation$

Finite Functions and Data Vectors

The finite functions $u(p)$, $v(q)$, and $w(r)$ introduced above are represented as multi-dimensional vectors of input and output data:

`inputu(i1, ..., idims)` for $u(p_1, \dots, p_N)$
`inputv(j1, ..., jdims)` for $v(q_1, \dots, q_N)$
`output(k1, ..., kdims)` for $w(r_1, \dots, r_N)$.

Parameter *dims* represents the number of dimensions and is equal to N .

The parameters *xshape*, *yshape*, and *zshape* define the shapes of input/output vectors:

`inputu(i1, ..., idims)` is defined if $1 \leq i_n \leq xshape(n)$ for every $n=1, \dots, dims$
`inputv(j1, ..., jdims)` is defined if $1 \leq j_n \leq yshape(n)$ for every $n=1, \dots, dims$
`output(k1, ..., kdims)` is defined if $1 \leq k_n \leq zshape(n)$ for every $n=1, \dots, dims$.

Relation between the input vectors and the functions u and v is defined by the following formulas:

`inputu(i1, ..., idims)` = $u(p_1, \dots, p_N)$, where $p_n = P_n^{\min} + (i_n - 1)$ for every n
`inputv(j1, ..., jdims)` = $v(q_1, \dots, q_N)$, where $q_n = Q_n^{\min} + (j_n - 1)$ for every n .

The relation between the output vector and the function $w(r)$ is similar (but only in the case when parameters *start* and *decimation* are not defined):

`output(k1, ..., kdims)` = $w(r_1, \dots, r_N)$, where $r_n = R_n^{\min} + (k_n - 1)$ for every n .

If the parameter *start* is defined, it must belong to the interval $R_n^{\min} \leq start(n) \leq R_n^{\max}$. If defined, the *start* parameter replaces $R^{\min}$ in the formula:

`output(k1, ..., kdims)` = $w(r_1, \dots, r_N)$, where $r_n = start(n) + (k_n - 1)$

If the parameter *decimation* is defined, it changes the relation according to the following formula:

`output(k1, ..., kdims)` = $w(r_1, \dots, r_N)$, where $r_n = R_n^{\min} + (k_n - 1) * decimation(n)$

If both parameters *start* and *decimation* are defined, the formula is as follows:

`output(k1, ..., kdims)` = $w(r_1, \dots, r_N)$, where $r_n = start(n) + (k_n - 1) * decimation(n)$

The convolution and correlation software checks the values of *zshape*, *start*, and *decimation* during task commitment. If r_n exceeds $R_n^{\max}$ for some $k_n, n=1, \dots, \text{dims}$, an error is raised.

Allocation of Data Vectors

Both parameter arrays *x* and *y* contain input data vectors in memory, while array *z* is intended for storing output data vector. To access the memory, the convolution and correlation software uses only pointers to these arrays and ignores the array shapes.

For parameters *x*, *y*, and *z*, you can provide one-dimensional arrays with the requirement that actual length of these arrays be sufficient to store the data vectors.

The allocation of the input and output data inside the arrays *x*, *y*, and *z* is described below assuming that the arrays are one-dimensional. Given multi-dimensional indices $i, j, k \in \mathbf{Z}^N$, one-dimensional indices $e, f, g \in \mathbf{Z}$ are defined such that:

`inputu(i1, ..., idims)` is allocated at `x(e)`

`inputv(j1, ..., jdims)` is allocated at `y(f)`

`output(k1, ..., kdims)` is allocated at `z(g)`.

The indices *e*, *f*, and *g* are defined as follows:

$e = 1 + \sum x\text{stride}(n) \cdot dx(n)$ (the sum is for all $n=1, \dots, \text{dims}$)

$f = 1 + \sum y\text{stride}(n) \cdot dy(n)$ (the sum is for all $n=1, \dots, \text{dims}$)

$g = 1 + \sum z\text{stride}(n) \cdot dz(n)$ (the sum is for all $n=1, \dots, \text{dims}$)

The distances $dx(n)$, $dy(n)$, and $dz(n)$ depend on the signum of the stride:

$dx(n) = i_n - 1$ if $x\text{stride}(n) > 0$, or $dx(n) = i_n - x\text{shape}(n)$ if $x\text{stride}(n) < 0$

$dy(n) = j_n - 1$ if $y\text{stride}(n) > 0$, or $dy(n) = j_n - y\text{shape}(n)$ if $y\text{stride}(n) < 0$

$dz(n) = k_n - 1$ if $z\text{stride}(n) > 0$, or $dz(n) = k_n - z\text{shape}(n)$ if $z\text{stride}(n) < 0$

The definitions of indices *e*, *f*, and *g* assume that indexes for arrays *x*, *y*, and *z* are started from unity:

`x(e)` is defined for $e=1, \dots, \text{length}(x)$

`y(f)` is defined for $f=1, \dots, \text{length}(y)$

`z(g)` is defined for $g=1, \dots, \text{length}(z)$

Below is a detailed explanation about how elements of the multi-dimensional output vector are stored in the array *z* for one-dimensional and two-dimensional cases.

One-dimensional case. If $\text{dims}=1$, then *zshape* is the number of the output values to be stored in the array *z*. The actual length of array *z* may be greater than *zshape* elements.

If $z\text{stride} > 1$, output values are stored with the stride: `output(1)` is stored to `z(1)`, `output(2)` is stored to `z(1+zstride)`, and so on. Hence, the actual length of *z* must be at least $1+z\text{stride}*(z\text{shape}-1)$ elements or more.

If $z\text{stride} < 0$, it still defines the stride between elements of array *z*. However, the order of the used elements is the opposite. For the *k*-th output value, `output(k)` is stored in `z(1+|zstride|*(zshape-k))`, where $|z\text{stride}|$ is the absolute value of *zstride*. The actual length of the array *z* must be at least $1+|z\text{stride}|*(z\text{shape} - 1)$ elements.

Two-dimensional case. If $\text{dims}=2$, the output data is a two-dimensional matrix. The value `zstride(1)` defines the stride inside matrix columns, that is, the stride between the `output(k1, k2)` and `output(k1+1, k2)` for every pair of indices k_1, k_2 . On the other hand, `zstride(2)` defines the stride between columns, that is, the stride between `output(k1, k2)` and `output(k1, k2+1)`.

If `zstride(2)` is greater than `zshape(1)`, this causes sparse allocation of columns. If the value of `zstride(2)` is smaller than `zshape(1)`, this may result in the transposition of the output matrix. For example, if `zshape = (2,3)`, you can define `zstride = (3,1)` to allocate output values like transposed matrix of the shape 3x2.

Whether `zstride` assumes this kind of transformations or not, you need to ensure that different elements output ($k_1, \dots, k_{\text{dims}}$) will be stored in different locations $z(g)$.

Summary Statistics

The Summary Statistics domain comprises a set of routines that compute basic statistical estimates for single and double precision multi-dimensional datasets.

See the definition of the supported operations in the [Mathematical Notation and Definitions](#) section.

The Summary Statistics routines calculate:

- raw and central moments up to the fourth order
- skewness and excess kurtosis (further referred to as *kurtosis* for brevity)
- variation coefficient
- quantiles and order statistics
- minimum and maximum
- variance-covariance/correlation matrix
- pooled/group variance-covariance matrix and mean
- partial variance-covariance/correlation matrix
- robust estimators for variance-covariance matrix and mean in presence of outliers
- raw/central partial sums up to the fourth order (for brevity referred to as *raw/central sums*)
- matrix of cross-products and sums of squares (for brevity referred to as *cross-product matrix*)
- median absolute deviation, mean absolute deviation

The library also contains functions to perform the following tasks:

- Detect outliers in datasets
- Support missing values in datasets
- Parameterize correlation matrices
- Compute quantiles for streaming data

You can access the Summary Statistics routines through the Fortran 90 and C89 language interfaces. You can use the C89 interface with later versions of the C/C++.

Intel MKL provides the `mkh_vs1.h` header file. All header files are in the directory

```
${MKL}/include
```

You can find examples that demonstrate calculation of the Summary Statistics estimates in the examples directories:

```
${MKL}/examples/vs1c
```

The Summary Statistics API is implemented through task objects, or tasks. A task object is a data structure, or a descriptor, holding parameters that determine a specific Summary Statistics operation. For example, such parameters may be precision, dimensions of user data, the matrix of the observations, or shapes of data arrays.

All the Summary Statistics routines process a task object as follows:

1. Create a task.
2. Modify settings of the task parameters.
3. Compute statistical estimates.
4. Destroy the task.

The Summary Statistics functions fall into the following categories:

Task Constructors - routines that create a new task object descriptor and set up most common parameters (dimension, number of observations, and matrix of the observations).

Task Editors - routines that can set or modify some parameter settings in the existing task descriptor.

Task Computation Routine - a routine that computes specified statistical estimates.

Task Destructor - a routine that deletes the task object and frees the memory.

A Summary Statistics task object contains a series of pointers to the input and output data arrays. You can read and modify the datasets and estimates at any time but you should allocate and release memory for such data.

See detailed information on the algorithms, API, and their usage in the *Intel® MKL Summary Statistics Application Notes* [[SS Notes](#)].

Naming Conventions

The names of Summary Statistics routines, types, and constants are case-sensitive and can contain lowercase and uppercase characters (`vslsSSEditQuantiles`).

The names of routines have the following structure:

```
vsl[datatype]SS<base name>
```

where

- `vsl` is a prefix indicating that the routine belongs to Intel MKL Vector Statistics.
- `[datatype]` specifies the type of the input and/or output data and can be `s` (single precision real type), `d` (double precision real type), or `i` (integer type).
- `SS/ss` indicates that the routine is intended for calculations of the Summary Statistics estimates.
- `<base name>` specifies a particular functionality that the routine is designed for, for example, `NewTask`, `Compute`, `DeleteTask`.

NOTE

The Summary Statistics routine `vslDeleteTask` for deletion of the task is independent of the data type and its name omits the `[datatype]` field.

Data Types

The Summary Statistics routines use the following data types for the calculations:

Type	Data Object
<code>VSLSSTaskPtr</code>	Pointer to a Summary Statistics task
<code>float</code>	Input/output user data in single precision
<code>double</code>	Input/output user data in double precision
<code>MKL_INT</code> or <code>long long</code>	Other data

NOTE

The actual size of the generic integer type is platform-specific and can be 32 or 64 bits in length. Before you compile your application, set an appropriate size for integers. See details in the 'Using the ILP64 Interface vs. LP64 Interface' section of the *Intel® MKL User's Guide*.

Parameters

The basic parameters in the task descriptor (addresses of dimensions, number of observations, and datasets) are assigned values when the task editors create or modify the task object. Other parameters are determined by the specific task and changed by the task editors.

Task Status and Error Reporting

The task status is an integer value, which is zero if no error is detected, or a specific non-zero error code otherwise. Negative status values indicate errors, and positive values indicate warnings. An error can be caused by invalid parameter values or a memory allocation failure.

The header files define symbolic names for the status codes. These names are defined as macros via the `#define` statements.

If no error is detected, the function returns the `VSL_STATUS_OK` code, which is defined as zero:

```
#define VSL_STATUS_OK 0
```

In the case of an error, the function returns a non-zero error code that specifies the origin of the failure. The header files define the following status codes for the Summary Statistics error codes:

Summary Statistics Status Codes

Status Code	Description
<code>VSL_STATUS_OK</code>	Operation is successfully completed.
<code>VSL_SS_ERROR_ALLOCATION_FAILURE</code>	Memory allocation has failed.
<code>VSL_SS_ERROR_BAD_DIMEN</code>	Dimension value is invalid.
<code>VSL_SS_ERROR_BAD_OBSERV_N</code>	Invalid number (zero or negative) of observations was obtained.
<code>VSL_SS_ERROR_STORAGE_NOT_SUPPORTED</code>	Storage format is not supported.
<code>VSL_SS_ERROR_BAD_INDC_ADDR</code>	Array of indices is not defined.
<code>VSL_SS_ERROR_BAD_WEIGHTS</code>	Array of weights contains negative values.
<code>VSL_SS_ERROR_BAD_MEAN_ADDR</code>	Array of means is not defined.
<code>VSL_SS_ERROR_BAD_2R_MOM_ADDR</code>	Array of the second order raw moments is not defined.
<code>VSL_SS_ERROR_BAD_3R_MOM_ADDR</code>	Array of the third order raw moments is not defined.
<code>VSL_SS_ERROR_BAD_4R_MOM_ADDR</code>	Array of the fourth order raw moments is not defined.
<code>VSL_SS_ERROR_BAD_2C_MOM_ADDR</code>	Array of the second order central moments is not defined.
<code>VSL_SS_ERROR_BAD_3C_MOM_ADDR</code>	Array of the third order central moments is not defined.
<code>VSL_SS_ERROR_BAD_4C_MOM_ADDR</code>	Array of the fourth order central moments is not defined.
<code>VSL_SS_ERROR_BAD_KURTOSIS_ADDR</code>	Array of kurtosis values is not defined.
<code>VSL_SS_ERROR_BAD_SKEWNESS_ADDR</code>	Array of skewness values is not defined.

Status Code	Description
VSL_SS_ERROR_BAD_MIN_ADDR	Array of minimum values is not defined.
VSL_SS_ERROR_BAD_MAX_ADDR	Array of maximum values is not defined.
VSL_SS_ERROR_BAD_VARIATION_ADDR	Array of variation coefficients is not defined.
VSL_SS_ERROR_BAD_COV_ADDR	Covariance matrix is not defined.
VSL_SS_ERROR_BAD_COR_ADDR	Correlation matrix is not defined.
VSL_SS_ERROR_BAD_QUANT_ORDER_ADDR	Array of quantile orders is not defined.
VSL_SS_ERROR_BAD_QUANT_ORDER	Quantile order value is invalid.
VSL_SS_ERROR_BAD_QUANT_ADDR	Array of quantiles is not defined.
VSL_SS_ERROR_BAD_ORDER_STATS_ADDR	Array of order statistics is not defined.
VSL_SS_ERROR_MOMORDER_NOT_SUPPORTED	Moment of requested order is not supported.
VSL_SS_NOT_FULL_RANK_MATRIX	Correlation matrix is not of full rank.
VSL_SS_ERROR_ALL_OBSERVS_OUTLIERS	All observations are outliers. (At least one observation must not be an outlier.)
VSL_SS_ERROR_BAD_ROBUST_COV_ADDR	Robust covariance matrix is not defined.
VSL_SS_ERROR_BAD_ROBUST_MEAN_ADDR	Array of robust means is not defined.
VSL_SS_ERROR_METHOD_NOT_SUPPORTED	Requested method is not supported.
VSL_SS_ERROR_NULL_TASK_DESCRIPTOR	Task descriptor is null.
VSL_SS_ERROR_BAD_OBSERV_ADDR	Dataset matrix is not defined.
VSL_SS_ERROR_BAD_ACCUM_WEIGHT_ADDR	Pointer to the variable that holds the value of accumulated weight is not defined.
VSL_SS_ERROR_SINGULAR_COV	Covariance matrix is singular.
VSL_SS_ERROR_BAD_POOLED_COV_ADDR	Pooled covariance matrix is not defined.
VSL_SS_ERROR_BAD_POOLED_MEAN_ADDR	Array of pooled means is not defined.
VSL_SS_ERROR_BAD_GROUP_COV_ADDR	Group covariance matrix is not defined.
VSL_SS_ERROR_BAD_GROUP_MEAN_ADDR	Array of group means is not defined.
VSL_SS_ERROR_BAD_GROUP_INDC_ADDR	Array of group indices is not defined.
VSL_SS_ERROR_BAD_GROUP_INDC	Group indices have improper values.
VSL_SS_ERROR_BAD_OUTLIERS_PARAMS_ADDR	Array of parameters for the outlier detection algorithm is not defined.
VSL_SS_ERROR_BAD_OUTLIERS_PARAMS_N_ADDR	Pointer to size of the parameter array for the outlier detection algorithm is not defined.
VSL_SS_ERROR_BAD_OUTLIERS_WEIGHTS_ADDR	Output of the outlier detection algorithm is not defined.
VSL_SS_ERROR_BAD_ROBUST_COV_PARAMS_ADDR	Array of parameters of the robust covariance estimation algorithm is not defined.

Status Code	Description
VSL_SS_ERROR_BAD_ROBUST_COV_PARAMS_N_ADDR	Pointer to the number of parameters of the algorithm for robust covariance is not defined.
VSL_SS_ERROR_BAD_STORAGE_ADDR	Pointer to the variable that holds the storage format is not defined.
VSL_SS_ERROR_BAD_PARTIAL_COV_IDX_ADDR	Array that encodes sub-components of a random vector for the partial covariance algorithm is not defined.
VSL_SS_ERROR_BAD_PARTIAL_COV_IDX	Array that encodes sub-components of a random vector for partial covariance has improper values.
VSL_SS_ERROR_BAD_PARTIAL_COV_ADDR	Partial covariance matrix is not defined.
VSL_SS_ERROR_BAD_PARTIAL_COR_ADDR	Partial correlation matrix is not defined.
VSL_SS_ERROR_BAD_MI_PARAMS_ADDR	Array of parameters for the Multiple Imputation method is not defined.
VSL_SS_ERROR_BAD_MI_PARAMS_N_ADDR	Pointer to number of parameters for the Multiple Imputation method is not defined.
VSL_SS_ERROR_BAD_MI_BAD_PARAMS_N	Size of the parameter array of the Multiple Imputation method is invalid.
VSL_SS_ERROR_BAD_MI_PARAMS	Parameters of the Multiple Imputation method are invalid.
VSL_SS_ERROR_BAD_MI_INIT_ESTIMATES_N_ADDR	Pointer to the number of initial estimates in the Multiple Imputation method is not defined.
VSL_SS_ERROR_BAD_MI_INIT_ESTIMATES_ADDR	Array of initial estimates for the Multiple Imputation method is not defined.
VSL_SS_ERROR_BAD_MI_SIMUL_VALS_ADDR	Array of simulated missing values in the Multiple Imputation method is not defined.
VSL_SS_ERROR_BAD_MI_SIMUL_VALS_N_ADDR	Pointer to the size of the array of simulated missing values in the Multiple Imputation method is not defined.
VSL_SS_ERROR_BAD_MI_ESTIMATES_N_ADDR	Pointer to the number of parameter estimates in the Multiple Imputation method is not defined.
VSL_SS_ERROR_BAD_MI_ESTIMATES_ADDR	Array of parameter estimates in the Multiple Imputation method is not defined.
VSL_SS_ERROR_BAD_MI_SIMUL_VALS_N	Invalid size of the array of simulated values in the Multiple Imputation method.
VSL_SS_ERROR_BAD_MI_ESTIMATES_N	Invalid size of an array to hold parameter estimates obtained using the Multiple Imputation method.
VSL_SS_ERROR_BAD_MI_OUTPUT_PARAMS	Array of output parameters in the Multiple Imputation method is not defined.
VSL_SS_ERROR_BAD_MI_PRIOR_N_ADDR	Pointer to the number of prior parameters is not defined.
VSL_SS_ERROR_BAD_MI_PRIOR_ADDR	Array of prior parameters is not defined.

Status Code	Description
VSL_SS_ERROR_BAD_MI_MISSING_VALS_N	Invalid number of missing values was obtained.
VSL_SS_SEMIDEFINITE_COR	Correlation matrix passed into the parameterization function is semi-definite.
VSL_SS_ERROR_BAD_PARAMTR_COR_ADDR	Correlation matrix to be parameterized is not defined.
VSL_SS_ERROR_BAD_COR	All eigenvalues of the correlation matrix to be parameterized are non-positive.
VSL_SS_ERROR_BAD_STREAM_QUANT_PARAMS_N_ADDR	Pointer to the number of parameters for the quantile computation algorithm for streaming data is not defined.
VSL_SS_ERROR_BAD_STREAM_QUANT_PARAMS_ADDR	Array of parameters of the quantile computation algorithm for streaming data is not defined.
VSL_SS_ERROR_BAD_STREAM_QUANT_PARAMS_N	Invalid number of parameters of the quantile computation algorithm for streaming data has been obtained.
VSL_SS_ERROR_BAD_STREAM_QUANT_PARAMS	Invalid parameters of the quantile computation algorithm for streaming data have been passed.
VSL_SS_ERROR_BAD_STREAM_QUANT_ORDER_ADDR	Array of the quantile orders for streaming data is not defined.
VSL_SS_ERROR_BAD_STREAM_QUANT_ORDER	Invalid quantile order for streaming data is defined.
VSL_SS_ERROR_BAD_STREAM_QUANT_ADDR	Array of quantiles for streaming data is not defined.
VSL_SS_ERROR_BAD_SUM_ADDR	Array of sums is not defined.
VSL_SS_ERROR_BAD_2R_SUM_ADDR	Array of raw sums of 2nd order is not defined.
VSL_SS_ERROR_BAD_3R_SUM_ADDR	Array of raw sums of 3rd order is not defined.
VSL_SS_ERROR_BAD_4R_SUM_ADDR	Array of raw sums of 4th order is not defined.
VSL_SS_ERROR_BAD_2C_SUM_ADDR	Array of central sums of 2nd order is not defined.
VSL_SS_ERROR_BAD_3C_SUM_ADDR	Array of central sums of 3rd order is not defined.
VSL_SS_ERROR_BAD_4C_SUM_ADDR	Array of central sums of 4th order is not defined.
VSL_SS_ERROR_BAD_CP_SUM_ADDR	Cross-product matrix is not defined.
VSL_SS_ERROR_BAD_MDAD_ADDR	Array of median absolute deviations is not defined.
VSL_SS_ERROR_BAD_MNAD_ADDR	Array of mean absolute deviations is not defined.
VSL_SS_ERROR_BAD_SORTED_OBSERV_ADDR	Array for storing observation sorting results is not defined.

Status Code	Description
VSL_SS_ERROR_ERROR_INDICES_NOT_SUPPORTED	Array of indices is not supported.

Routines for robust covariance estimation, outlier detection, partial covariance estimation, multiple imputation, and parameterization of a correlation matrix can return internal error codes that are related to a specific implementation. Such error codes indicate invalid input data or other bugs in the Intel MKL routines other than the Summary Statistics routines.

Task Constructors

Task constructors are routines intended for creating a new task descriptor and setting up basic parameters.

NOTE

If the constructor fails to create a task descriptor, it returns the `NULL` task pointer.

vs1SSNewTask

Creates and initializes a new summary statistics task descriptor.

Syntax

```
status = vs1sSSNewTask(&task, p, n, xstorage, x, w, indices);
```

```
status = vsldSSNewTask(&task, p, n, xstorage, x, w, indices);
```

Include Files

- `mk1.h`

Input Parameters

Name	Type	Description
<i>p</i>	<code>const MKL_INT</code>	Dimension of the task, number of variables
<i>n</i>	<code>const MKL_INT</code>	Number of observations
<i>xstorage</i>	<code>const MKL_INT</code>	Storage format of matrix of observations
<i>x</i>	<code>const float*</code> for <code>vs1sSSNewTask</code> <code>const double*</code> for <code>vsldSSNewTask</code>	Matrix of observations
<i>w</i>	<code>const float*</code> for <code>vs1sSSNewTask</code> <code>const double*</code> for <code>vsldSSNewTask</code>	Array of weights of size <i>n</i> . Elements of the arrays are non-negative numbers. If a <code>NULL</code> pointer is passed, each observation is assigned weight equal to 1.
<i>indices</i>	<code>const MKL_INT*</code>	Array of vector components that will be processed. Size of array is <i>p</i> . If a <code>NULL</code> pointer is passed, all components of random vector are processed.

Output Parameters

Name	Type	Description
<i>task</i>	VSLSSTaskPtr*	Descriptor of the task
<i>status</i>	int	Set to VSL_STATUS_OK if the task is created successfully, otherwise a non-zero error code is returned.

Description

Each `vslssNewTask` constructor routine creates a new summary statistics task descriptor with the user-specified value for a required parameter, dimension of the task. The optional parameters (matrix of observations, its storage format, number of observations, weights of observations, and indices of the random vector components) are set to their default values.

The observations of random p -dimensional vector $\xi = (\xi_1, \dots, \xi_i, \dots, \xi_p)$, which are n vectors of dimension p , are passed as a one-dimensional array x . The parameter *xstorage* defines the storage format of the observations and takes one of the possible values listed in [Table "Storage format of matrix of observations and order statistics"](#).

Storage format of matrix of observations, order statistics, and matrix of sorted observations

Parameter	Description
VSL_SS_MATRIX_STORAGE_ROWS	The observations of random vector ξ are packed by rows: n data points for the vector component ξ_1 come first, n data points for the vector component ξ_2 come second, and so forth.
VSL_SS_MATRIX_STORAGE_COLS	The observations of random vector ξ are packed by columns: the first p -dimensional observation of the vector ξ comes first, the second p -dimensional observation of the vector comes second, and so forth.

A one-dimensional array w of size n contains non-negative weights assigned to the observations. You can pass a `NULL` array into the constructor. In this case, each observation is assigned the default value of the weight.

You can choose vector components for which you wish to compute statistical estimates. If an element of the vector indices of size p contains 0, the observations that correspond to this component are excluded from the calculations. If you pass the `NULL` value of the parameter into the constructor, statistical estimates for all random variables are computed.

If the constructor fails to create a task descriptor, it returns the `NULL` task pointer.

Task Editors

Task editors are intended to set up or change the task parameters listed in [Table "Parameters of Summary Statistics Task to Be Initialized or Modified"](#). As an example, to compute the sample mean for a one-dimensional dataset, initialize a variable for the mean value, and pass its address into the task as shown in the example below:

```
#define DIM    1
#define N    1000

int main()
{
    VSLSSTaskPtr task;
    double x[N];
```

```
double mean;
MKL_INT p, n, xstorage;
int status;
/* initialize variables used in the computations of sample mean */
p = DIM;
n = N;
xstorage = VSL_SS_MATRIX_STORAGE_ROWS;
mean = 0.0;

/* create task */
status = vsldSSNewTask( &task, &p, &n, &xstorage, x, 0, 0 );

/* initialize task parameters */
status = vsldSSEditTask( task, VSL_SS_ED_MEAN, &mean );

/* compute mean using SS fast method */
status = vsldSSCompute(task, VSL_SS_MEAN, VSL_SS_METHOD_FAST );

/* deallocate task resources */
status = vslSSDeleteTask( &task );

return 0;
}
```

Use the single (`vslssedittask`) or double (`vsldssedittask`) version of an editor, to initialize single or double precision version task parameters, respectively. Use an integer version of an editor (`vslisedittask`) to initialize parameters of the integer type.

Table "Summary Statistics Task Editors" lists the task editors for Summary Statistics. Each of them initializes and/or modifies a respective group of related parameters.

Summary Statistics Task Editors

Editor	Description
<code>vslSSEditTask</code>	Changes a pointer in the task descriptor.
<code>vslSSEditMoments</code>	Changes pointers to arrays associated with raw and central moments.
<code>vslSSEditSums</code>	Modifies the pointers to arrays that hold sum estimates.
<code>vslSSEditCovCor</code>	Changes pointers to arrays associated with covariance and/or correlation matrices.
<code>vslSSEditCP</code>	Modifies the pointers to cross-product matrix parameters.
<code>vslSSEditPartialCovCor</code>	Changes pointers to arrays associated with partial covariance and/or correlation matrices.
<code>vslSSEditQuantiles</code>	Changes pointers to arrays associated with quantile/order statistics calculations.
<code>vslSSEditStreamQuantiles</code>	Changes pointers to arrays for quantile related calculations for streaming data.
<code>vslSSEditPooledCovariance</code>	Changes pointers to arrays associated with algorithms related to a pooled covariance matrix.
<code>vslSSEditRobustCovariance</code>	Changes pointers to arrays for robust estimation of a covariance matrix and mean.
<code>vslSSEditOutliersDetection</code>	Changes pointers to arrays for detection of outliers.

Editor	Description
<code>vslsSSEditMissingValues</code>	Changes pointers to arrays associated with the method of supporting missing values in a dataset.
<code>vslsSSEditCorParameterization</code>	Changes pointers to arrays associated with the algorithm for parameterization of a correlation matrix.

NOTE

You can use the `NULL` task pointer in calls to editor routines. In this case, the routine is terminated and no system crash occurs.

vslsSSEditTask

Modifies address of an input/output parameter in the task descriptor.

Syntax

```
status = vslsSSEditTask(task, parameter, par_addr);
status = vsldSSEditTask(task, parameter, par_addr);
status = vsliSSEditTask(task, parameter, par_addr);
```

Include Files

- `mkl.h`

Input Parameters

Name	Type	Description
<code>task</code>	<code>VSLSSTaskPtr</code>	Descriptor of the task
<code>parameter</code>	<code>const MKL_INT</code>	Parameter to change
<code>par_addr</code>	<code>const float*</code> for <code>vslsSSEditTask</code> <code>const double*</code> for <code>vsldSSEditTask</code> <code>const MKL_INT*</code> for <code>vsliSSEditTask</code>	Address of the new parameter

Output Parameters

Name	Type	Description
<code>status</code>	<code>int</code>	Current status of the task

Description

The `vslsSSEditTask` routine replaces the pointer to the parameter stored in the Summary Statistics task descriptor with the `par_addr` pointer. If you pass the `NULL` pointer to the editor, no changes take place in the task and a corresponding error code is returned. See [Table "Parameters of Summary Statistics Task to Be Initialized or Modified"](#) for the predefined values of the parameter.

Use the single (`vslsssedittask`) or double (`vsldsssedittask`) version of the editor, to initialize single or double precision version task parameters, respectively. Use an integer version of the editor (`vsliessedittask`) to initialize parameters of the integer type.

Parameters of Summary Statistics Task to Be Initialized or Modified

Parameter Value	Type	Purpose	Initialization
VSL_SS_ED_DIMEN	i	Address of a variable that holds the task dimension	Required. Positive integer value.
VSL_SS_ED_OBSERV_N	i	Address of a variable that holds the number of observations	Required. Positive integer value.
VSL_SS_ED_OBSERV	d, s	Address of the observation matrix	Required. Provide the matrix containing your observations.
VSL_SS_ED_OBSERV_STORAGE	i	Address of a variable that holds the storage format for the observation matrix	Required. Provide a storage format supported by the library whenever you pass a matrix of observations. ¹
VSL_SS_ED_INDC	i	Address of the array of indices	Optional. Provide this array if you need to process individual components of the random vector. Set entry <i>i</i> of the array to one to include the <i>i</i> th coordinate in the analysis. Set entry <i>i</i> of the array to zero to exclude the <i>i</i> th coordinate from the analysis.
VSL_SS_ED_WEIGHTS	d, s	Address of the array of observation weights	Optional. If the observations have weights different from the default weight (one), set entries of the array to non-negative floating point values.
VSL_SS_ED_MEAN	d, s	Address of the array of means	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.
VSL_SS_ED_2R_MOM	d, s	Address of an array of raw moments of the second order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.
VSL_SS_ED_3R_MOM	d, s	Address of an array of raw moments of the third order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.
VSL_SS_ED_4R_MOM	d, s	Address of an array of raw moments of the fourth order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.

Parameter Value	Type	Purpose	Initialization
VSL_SS_ED_2C_MOM	d, s	Address of an array of central moments of the second order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array. Make sure you also provide arrays for raw moments of the first and second order.
VSL_SS_ED_3C_MOM	d, s	Address of an array of central moments of the third order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array. Make sure you also provide arrays for raw moments of the first, second, and third order.
VSL_SS_ED_4C_MOM	d, s	Address of an array of central moments of the fourth order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array. Make sure you also provide arrays for raw moments of the first, second, third, and fourth order.
VSL_SS_ED_KURTOSIS	d, s	Address of the array of kurtosis estimates	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array. Make sure you also provide arrays for raw moments of the first, second, third, and fourth order.
VSL_SS_ED_SKEWNESS	d, s	Address of the array of skewness estimates	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array. Make sure you also provide arrays for raw moments of the first, second, and third order.
VSL_SS_ED_MIN	d, s	Address of the array of minimum estimates	Optional. Set entries of array to meaningful values, such as the values of the first observation.
VSL_SS_ED_MAX	d, s	Address of the array of maximum estimates	Optional. Set entries of array to meaningful values, such as the values of the first observation.

Parameter Value	Type	Purpose	Initialization
VSL_SS_ED_VARIATION	d, s	Address of the array of variation coefficients	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array. Make sure you also provide arrays for raw moments of the first and second order.
VSL_SS_ED_COV	d, s	Address of a covariance matrix	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Make sure you also provide an array for the mean.
VSL_SS_ED_COV_STORAGE	i	Address of the variable that holds the storage format for a covariance matrix	Required. Provide a storage format supported by the library whenever you intend to compute the covariance matrix. ²
VSL_SS_ED_COR	d, s	Address of a correlation matrix	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. If you initialize the matrix in non-trivial way, make sure that the main diagonal contains variance values. Also, provide an array for the mean.
VSL_SS_ED_COR_STORAGE	i	Address of the variable that holds the correlation storage format for a correlation matrix	Required. Provide a storage format supported by the library whenever you intend to compute the correlation matrix. ²
VSL_SS_ED_ACCUM_WEIGHT	d, s	Address of the array of size 2 that holds the accumulated weight (sum of weights) in the first position and the sum of weights squared in the second position	Optional. Set the entries of the matrix to meaningful values (typically zero) if you intend to do progressive processing of the dataset or need the sum of weights and sum of squared weights assigned to observations.
VSL_SS_ED_QUANT_ORDER_N	i	Address of the variable that holds the number of quantile orders	Required. Positive integer value. Provide the number of quantile orders whenever you compute quantiles.
VSL_SS_ED_QUANT_ORDER	d, s	Address of the array of quantile orders	Required. Set entries of array to values from the interval (0,1). Provide this parameter whenever you compute quantiles.

Parameter Value	Type	Purpose	Initialization
VSL_SS_ED_QUANT_QUANTILE S	d, s	Address of the array of quantiles	None.
VSL_SS_ED_ORDER_STATS	d, s	Address of the array of order statistics	None.
VSL_SS_ED_GROUP_INDC	i	Address of the array of group indices used in computation of a pooled covariance matrix	Required. Set entry i to integer value k if the observation belongs to group k . Values of k take values in the range $[0, g-1]$, where g is the number of groups.
VSL_SS_ED_POOLED_COV_STO RAGE	i	Address of a variable that holds the storage format for a pooled covariance matrix	Required. Provide a storage format supported by the library whenever you intend to compute pooled covariance. ²
VSL_SS_ED_POOLED_MEAN	d, s	Address of an array of pooled means	None.
VSL_SS_ED_POOLED_COV	d, s	Address of pooled covariance matrices	None.
VSL_SS_ED_GROUP_COV_INDC	i	Address of an array of indices for which covariance/means should be computed	Optional. Set the k th entry of the array to 1 if you need group covariance and mean for group k ; otherwise set it to zero.
VSL_SS_ED_REQ_GROUP_INDC	i	Address of an array of indices for which group estimates such as covariance or means are requested	Optional. Set the k th entry of the array to 1 if you need an estimate for group k ; otherwise set it to zero.
VSL_SS_ED_GROUP_MEANS	i	Address of an array of group means	None.
VSL_SS_ED_GROUP_COV_STOR AGE	d, s	Address of a variable that holds the storage format for a group covariance matrix	Required. Provide a storage format supported by the library whenever you intend to get group covariance. ²
VSL_SS_ED_GROUP_COV	d, s	Address of group covariance matrices	None.
VSL_SS_ED_ROBUST_COV_STO RAGE	d, s	Address of a variable that holds the storage format for a robust covariance matrix	Required. Provide a storage format supported by the library whenever you compute robust covariance ² .
VSL_SS_ED_ROBUST_COV_PAR AMS_N	i	Address of a variable that holds the number of algorithmic parameters of the method for robust covariance estimation	Required. Set to the number of TBS parameters, <i>VSL_SS_TBS_PARAMS_N</i> .

Parameter Value	Type	Purpose	Initialization
VSL_SS_ED_ROBUST_COV_PARAMS	d, s	Address of an array of parameters of the method for robust estimation of a covariance	Required. Set the entries of the array according to the description in vslSSEditRobustCovariance .
VSL_SS_ED_ROBUST_MEAN	i	Address of an array of robust means	None.
VSL_SS_ED_ROBUST_COV	d, s	Address of a robust covariance matrix	None.
VSL_SS_ED_OUTLIERS_PARAMS_N	d, s	Address of a variable that holds the number of parameters of the outlier detection method	Required. Set to the number of outlier detection parameters, <i>VSL_SS_BACON_PARAMS_N</i> .
VSL_SS_ED_OUTLIERS_PARAMS	i	Address of an array of algorithmic parameters for the outlier detection method	Required. Set the entries of the array according to the description in vslSSEditOutliersDetection .
VSL_SS_ED_OUTLIERS_WEIGHT	d, s	Address of an array of weights assigned to observations by the outlier detection method	None.
VSL_SS_ED_ORDER_STATS_STORAGE	d, s	Address of a variable that holds the storage format of an order statistics matrix	Required. Provide a storage format supported by the library whenever you compute a matrix of order statistics. ¹
VSL_SS_ED_PARTIAL_COV_IDX	i	Address of an array that encodes subcomponents of a random vector	Required. Set the entries of the array according to the description in vslSSEditPartialCovCor .
VSL_SS_ED_PARTIAL_COV	d, s	Address of a partial covariance matrix	None.
VSL_SS_ED_PARTIAL_COV_STORAGE	i	Address of a variable that holds the storage format of a partial covariance matrix	Required. Provide a storage format supported by the library whenever you compute the partial covariance. ²
VSL_SS_ED_PARTIAL_COR	d, s	Address of a partial correlation matrix	None.
VSL_SS_ED_PARTIAL_COR_STORAGE	i	Address of a variable that holds the storage format for a partial correlation matrix	Required. Provide a storage format supported by the library whenever you compute the partial correlation. ²
VSL_SS_ED_MI_PARAMS_N	i	Address of a variable that holds the number of algorithmic parameters for the Multiple Imputation method	Required. Set to the number of MI parameters, <i>VSL_SS_MI_PARAMS_SIZE</i> .

Parameter Value	Type	Purpose	Initialization
VSL_SS_ED_MI_PARAMS	d, s	Address of an array of algorithmic parameters for the Multiple Imputation method	Required. Set entries of the array according to the description in vslSSEditMissingValues .
VSL_SS_ED_MI_INIT_ESTIMATE_N	i	Address of a variable that holds the number of initial estimates for the Multiple Imputation method	Optional. Set to $p+p*(p+1)/2$, where p is the task dimension.
VSL_SS_ED_MI_INIT_ESTIMATE	d, s	Address of an array of initial estimates for the Multiple Imputation method	Optional. Set the values of the array according to the description in "Basic Components of the Multiple Imputation Function in Summary Statistics" in the <i>Intel® MKL Summary Statistics Application Notes</i> document [SS Notes].
VSL_SS_ED_MI_SIMUL_VALS_N	i	Address of a variable that holds the number of simulated values in the Multiple Imputation method	Optional. Positive integer indicating the number of missing points in the observation matrix.
VSL_SS_ED_MI_SIMUL_VALS	d, s	Address of an array of simulated values in the Multiple Imputation method	None.
VSL_SS_ED_MI_ESTIMATES_N	i	Address of a variable that holds the number of estimates obtained as a result of the Multiple Imputation method	Optional. Positive integer number defined according to the description in "Basic Components of the Multiple Imputation Function in Summary Statistics" in the <i>Intel® MKL Summary Statistics Application Notes</i> document [SS Notes].
VSL_SS_ED_MI_ESTIMATES	d, s	Address of an array of estimates obtained as a result of the Multiple Imputation method	None.
VSL_SS_ED_MI_PRIOR_N	i	Address of a variable that holds the number of prior parameters for the Multiple Imputation method	Optional. If you pass a user-defined array of prior parameters, set this parameter to $(p^2+3*p+4)/2$, where p is the task dimension.
VSL_SS_ED_MI_PRIOR	d, s	Address of an array of prior parameters for the Multiple Imputation method	Optional. Set entries of the array of prior parameters according to the description in "Basic Components of the Multiple Imputation Function in Summary

Parameter Value	Type	Purpose	Initialization
			Statistics" in the <i>Intel® MKL Summary Statistics Application Notes</i> document [SS Notes].
VSL_SS_ED_PARAMTR_COR	d, s	Address of a parameterized correlation matrix	None.
VSL_SS_ED_PARAMTR_COR_STORAGE	i	Address of a variable that holds the storage format of a parameterized correlation matrix	Required. Provide a storage format supported by the library whenever you compute the parameterized correlation matrix. ²
VSL_SS_ED_STREAM_QUANT_PARAMS_N	i	Address of a variable that holds the number of parameters of a quantile computation method for streaming data	Required. Set to the number of quantile computation parameters, <i>VSL_SS_SQUANTS_ZW_PARAMS_N</i> .
VSL_SS_ED_STREAM_QUANT_PARAMS	d, s	Address of an array of parameters of a quantile computation method for streaming data	Required. Set the entries of the array according to the description in "Computing Quantiles for Streaming Data" in the <i>Intel® MKL Summary Statistics Application Notes</i> document [SS Notes].
VSL_SS_ED_STREAM_QUANT_ORDER_N	i	Address of a variable that holds the number of quantile orders for streaming data	Required. Positive integer value.
VSL_SS_ED_STREAM_QUANT_ORDER	d, s	Address of an array of quantile orders for streaming data	Required. Set entries of the array to values from the interval (0,1). Provide this parameter whenever you compute quantiles.
VSL_SS_ED_STREAM_QUANT_QUANTILES	d, s	Address of an array of quantiles for streaming data	None.
VSL_SS_ED_SUM	d, s	Address of array of sums	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.
VSL_SS_ED_2R_SUM	d, s	Address of array of raw sums of 2nd order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.
VSL_SS_ED_3R_SUM	d, s	Address of array of raw sums of 3rd order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.

Parameter Value	Type	Purpose	Initialization
VSL_SS_ED_4R_SUM	d, s	Address of array of raw sums of 4th order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.
VSL_SS_ED_2C_SUM	d, s	Address of array of central sums of 2nd order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.
VSL_SS_ED_3C_SUM	d, s	Address of array of central sums of 3rd order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.
VSL_SS_ED_4C_SUM	d, s	Address of array of central sums of 4th order	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.
VSL_SS_ED_CP	d, s	Address of cross-product matrix	Optional. Set entries of the array to meaningful values (typically zero) if you intend to compute a progressive estimate. Otherwise, do not initialize the array.
VSL_SS_ED_MDAD	d, s	Address of array of median absolute deviations	None.
VSL_SS_ED_MNAD	d, s	Address of array of mean absolute deviations	None.
VSL_SS_ED_SORTED_OBSERV	d, s	Address of the array that stores sorted results	None.
VSL_SS_ED_SORTED_OBSERV_STORAGE	i	Address of a variable that holds the storage format of an output matrix	Required. Provide a supported storage format whenever you specify sorting of the observation matrix.

1. See [Table: "Storage format of matrix of observations and order statistics"](#) for storage formats.
2. See [Table: "Storage formats of a variance-covariance/correlation matrix"](#) for storage formats.

vslSSEditMoments

Modifies the pointers to arrays that hold moment estimates.

Syntax

```
status = vslsSSEditMoments(task, mean, r2m, r3m, r4m, c2m, c3m, c4m);
status = vsldSSEditMoments(task, mean, r2m, r3m, r4m, c2m, c3m, c4m);
```

Include Files

- `mkl.h`

Input Parameters

Name	Type	Description
<code>task</code>	<code>VSLSTaskPtr</code>	Descriptor of the task
<code>mean</code>	<code>const float* for vslsSSEditMoments</code> <code>const double* for vsldSSEditMoments</code>	Pointer to the array of means
<code>r2m</code>	<code>const float* for vslsSSEditMoments</code> <code>const double* for vsldSSEditMoments</code>	Pointer to the array of raw moments of the 2 nd order
<code>r3m</code>	<code>const float* for vslsSSEditMoments</code> <code>const double* for vsldSSEditMoments</code>	Pointer to the array of raw moments of the 3 rd order
<code>r4m</code>	<code>const float* for vslsSSEditMoments</code> <code>const double* for vsldSSEditMoments</code>	Pointer to the array of raw moments of the 4 th order
<code>c2m</code>	<code>const float* for vslsSSEditMoments</code> <code>const double* for vsldSSEditMoments</code>	Pointer to the array of central moments of the 2 nd order
<code>c3m</code>	<code>const float* for vslsSSEditMoments</code> <code>const double* for vsldSSEditMoments</code>	Pointer to the array of central moments of the 3 rd order
<code>c4m</code>	<code>const float* for vslsSSEditMoments</code> <code>const double* for vsldSSEditMoments</code>	Pointer to the array of central moments of the 4 th order

Output Parameters

Name	Type	Description
<code>status</code>	<code>int</code>	Current status of the task

Description

The `vslsSSEditMoments` routine replaces pointers to the arrays that hold estimates of raw and central moments with values passed as corresponding parameters of the routine. If an input parameter is `NULL`, the value of the relevant parameter remains unchanged.

vslsSSEditSums

Modifies the pointers to arrays that hold sum estimates.

Syntax

```
status = vslsSSEditSums(task, sum, r2s, r3s, r4s, c2s, c3s, c4s);
```

```
status = vsldSSEditSums(task, sum, r2s, r3s, r4s, c2s, c3s, c4s);
```

Include Files

- `mkl.h`

Input Parameters

Name	Type	Description
<i>task</i>	VSLSTaskPtr	Descriptor of the task
<i>sum</i>	const float* for <code>vslsSSEditSums</code> const double* for <code>vsldSSEditSums</code>	Pointer to the array of sums
<i>r2s</i>	const float* for <code>vslsSSEditSums</code> const double* for <code>vsldSSEditSums</code>	Pointer to the array of raw sums of the second order
<i>r3s</i>	const float* for <code>vslsSSEditSums</code> const double* for <code>vsldSSEditSums</code>	Pointer to the array of raw sums of the third order
<i>r4s</i>	const float* for <code>vslsSSEditSums</code> const double* for <code>vsldSSEditSums</code>	Pointer to the array of raw sums of the fourth order
<i>c2s</i>	const float* for <code>vslsSSEditSums</code> const double* for <code>vsldSSEditSums</code>	Pointer to the array of central sums of the second order
<i>c3s</i>	const float* for <code>vslsSSEditSums</code> const double* for <code>vsldSSEditSums</code>	Pointer to the array of central sums of the third order
<i>c4s</i>	const float* for <code>vslsSSEditSums</code> const double* for <code>vsldSSEditSums</code>	Pointer to the array of central sums of the fourth order

Output Parameters

Name	Type	Description
<i>status</i>	int	Current status of the task

Description

The `vslsSSEditSums` routine replaces pointers to the arrays that hold estimates of raw and central sums with values passed as corresponding parameters of the routine. If an input parameter is `NULL`, the value of the relevant parameter remains unchanged.

vslsSSEditCovCor

Modifies the pointers to covariance/correlation/cross-product parameters.

Syntax

```
status = vslsSSEditCovCor(task, mean, cov, cov_storage, cor, cor_storage);
status = vsldSSEditCovCor(task, mean, cov, cov_storage, cor, cor_storage);
```

Include Files

- `mk1.h`

Input Parameters

Name	Type	Description
<i>task</i>	VSLSSTaskPtr	Descriptor of the task
<i>mean</i>	const float* for vslsSSEditCovCor const double* for vsldSSEditCovCor	Pointer to the array of means
<i>cov</i>	const float* for vslsSSEditCovCor const double* for vsldSSEditCovCor	Pointer to a covariance matrix
<i>cov_storage</i>	const MKL_INT*	Pointer to the storage format of the covariance matrix
<i>cor</i>	const float* for vslsSSEditCovCor const double* for vsldSSEditCovCor	Pointer to a correlation matrix
<i>cor_storage</i>	const MKL_INT*	Pointer to the storage format of the correlation matrix

Output Parameters

Name	Type	Description
<i>status</i>	int	Current status of the task

Description

The `vslsSSEditCovCor` routine replaces pointers to the array of means, covariance/correlation arrays, and their storage format with values passed as corresponding parameters of the routine. See [Table "Storage formats of a variance-covariance/correlation/cross-product matrix"](#) for possible values of the *cov_storage* and *cor_storage* parameters. If an input parameter is `NULL`, the old value of the parameter remains unchanged in the Summary Statistics task descriptor.

Storage formats of a variance-covariance/correlation/cross-product matrix

Parameter	Description
VSL_SS_MATRIX_STORAGE_FULL	A symmetric variance-covariance/correlation/cross-product matrix is a one-dimensional array with elements $c(i, j)$ stored as $cp(i * p + j)$. The size of the array is $p * p$.
VSL_SS_MATRIX_STORAGE_L_PACKED	A symmetric variance-covariance/correlation/cross-product matrix with elements $c(i, j)$ is packed as a one-dimensional array $cp(i + (2n - j) * (j - 1) / 2)$ for $j \leq i$. The size of the array is $p * (p + 1) / 2$.
VSL_SS_MATRIX_STORAGE_U_PACKED	A symmetric variance-covariance/correlation/cross-product matrix with elements $c(i, j)$ is packed as a one-dimensional array $cp(i + j * (j - 1) / 2)$ for $i \leq j$. The size of the array is $p * (p + 1) / 2$.

vsISSEditCP

Modifies the pointers to cross-product matrix parameters.

Syntax

```
status = vslsSSEditCP(task, mean, sum, cp, cp_storage);
status = vsldSSEditCP(task, mean, sum, cp, cp_storage);
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>task</i>	VSLSTaskPtr	Descriptor of the task
<i>mean</i>	const float* for vslsSSEditCP const double* for vsldSSEditCP	Pointer to array of means
<i>sum</i>	const float* for vslsSSEditCP const double* for vsldSSEditCP	Pointer to array of sums
<i>cp</i>	const float* for vslsSSEditCP const double* for vsldSSEditCP	Pointer to a cross-product matrix
<i>cp_storage</i>	const MKL_INT*	Pointer to the storage format of the cross-product matrix

Output Parameters

Name	Type	Description
<i>status</i>	int	Current status of the task

Description

The `vslsSSEditCP` routine replaces pointers to the array of means, array of sums, cross-product matrix, and its storage format with values passed as corresponding parameters of the routine. See [Table: "Storage formats of a variance-covariance/correlation/cross-product matrix"](#) for possible values of the *cp_storage* parameter. If an input parameter is `NULL`, the old value of the parameter remains unchanged in the Summary Statistics task descriptor.

Storage formats of a variance-covariance/correlation/cross-product matrix

Parameter	Description
VSL_SS_MATRIX_STORAGE_FULL	A symmetric variance-covariance/correlation/cross-product matrix is a one-dimensional array with elements $c(i, j)$ stored as $cp(i * p + j)$. The size of the array is $p * p$.
VSL_SS_MATRIX_STORAGE_L_PACKED	A symmetric variance-covariance/correlation/cross-product matrix with elements $c(i, j)$ is packed as a one-dimensional array $cp(i + (2n - j) * (j - 1) / 2)$ for $j \leq i$. The size of the array is $p * (p + 1) / 2$.

Parameter	Description
VSL_SS_MATRIX_STORAGE_U_PACKED	A symmetric variance-covariance/correlation/cross-product matrix with elements $c(i, j)$ is packed as a one-dimensional array $cp(i + j*(j - 1)/2)$ for $i \leq j$. The size of the array is $p*(p + 1)/2$.

vslsSEditPartialCovCor

Modifies the pointers to partial covariance/correlation parameters.

Syntax

```
status = vslsSEditPartialCovCor(task, p_idx_array, cov, cov_storage, cor,
cor_storage, p_cov, p_cov_storage, p_cor, p_cor_storage);
```

```
status = vsldSEditPartialCovCor(task, p_idx_array, cov, cov_storage, cor,
cor_storage, p_cov, p_cov_storage, p_cor, p_cor_storage);
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>task</i>	VSLSSTaskPtr	Descriptor of the task
<i>p_idx_array</i>	const MKL_INT*	Pointer to the array that encodes indices of subcomponents Z and Y of the random vector as described in section Mathematical Notation and Definitions . <i>p_idx_array[i]</i> equals to -1 if the <i>i</i> -th component of the random vector belongs to Z 1, if the <i>i</i> -th component of the random vector belongs to Y.
<i>cov</i>	const float* for vslsSEditPartialCovCor const double* for vsldSEditPartialCovCor	Pointer to a covariance matrix
<i>cov_storage</i>	const MKL_INT*	Pointer to the storage format of the covariance matrix
<i>cor</i>	const float* for vslsSEditPartialCovCor const double* for vsldSEditPartialCovCor	Pointer to a correlation matrix
<i>cor_storage</i>	const MKL_INT*	Pointer to the storage format of the correlation matrix

Name	Type	Description
<i>p_cov</i>	const float* for vslsSSEditPartialCovCor const double* for vsldSSEditPartialCovCor	Pointer to a partial covariance matrix
<i>p_cov_storage</i>	const MKL_INT*	Pointer to the storage format of the partial covariance matrix
<i>p_cor</i>	const float* for vslsSSEditPartialCovCor const double* for vsldSSEditPartialCovCor	Pointer to a partial correlation matrix
<i>p_cor_storage</i>	const MKL_INT*	Pointer to the storage format of the partial correlation matrix

Output Parameters

Name	Type	Description
<i>status</i>	int	Current status of the task

Description

The `vslsSSEditPartialCovCor` routine replaces pointers to covariance/correlation arrays, partial covariance/correlation arrays, and their storage format with values passed as corresponding parameters of the routine. See [Table "Storage formats of a variance-covariance/correlation matrix"](#) for possible values of the *cov_storage*, *cor_storage*, *p_cov_storage*, and *p_cor_storage* parameters. If an input parameter is `NULL`, the old value of the parameter remains unchanged in the Summary Statistics task descriptor.

vslSSEditQuantiles

Modifies the pointers to parameters related to quantile computations.

Syntax

```
status = vslsSSEditQuantiles(task, quant_order_n, quant_order, quants, order_stats,
order_stats_storage);
```

```
status = vsldSSEditQuantiles(task, quant_order_n, quant_order, quants, order_stats,
order_stats_storage);
```

Include Files

- `mkl.h`

Input Parameters

Name	Type	Description
<i>task</i>	VSLSSTaskPtr	Descriptor of the task
<i>quant_order_n</i>	const MKL_INT*	Pointer to the number of quantile orders

Name	Type	Description
<i>quant_order</i>	const float* for vslsSSEditQuantiles const double* for vsldSSEditQuantiles	Pointer to the array of quantile orders
<i>quants</i>	const float* for vslsSSEditQuantiles const double* for vsldSSEditQuantiles	Pointer to the array of quantiles
<i>order_stats</i>	const float* for vslsSSEditQuantiles const double* for vsldSSEditQuantiles	Pointer to the array of order statistics
<i>order_stats_storage</i>	const MKL_INT*	Pointer to the storage format of the order statistics array

Output Parameters

Name	Type	Description
<i>status</i>	int	Current status of the task

Description

The `vslsSSEditQuantiles` routine replaces pointers to the number of quantile orders, the array of quantile orders, the array of quantiles, the array that holds order statistics, and the storage format for the order statistics with values passed into the routine. See [Table "Storage format of matrix of observations and order statistics"](#) for possible values of the *order_statistics_storage* parameter. If an input parameter is `NULL`, the corresponding parameter in the Summary Statistics task descriptor remains unchanged.

vsldSSEditStreamQuantiles

Modifies the pointers to parameters related to quantile computations for streaming data.

Syntax

```
status = vslsSSEditStreamQuantiles(task, quant_order_n, quant_order, quants, nparams,
params);
```

```
status = vsldSSEditStreamQuantiles(task, quant_order_n, quant_order, quants, nparams,
params);
```

Include Files

- `mkh.h`

Input Parameters

Name	Type	Description
<i>task</i>	VSLSSTaskPtr	Descriptor of the task

Name	Type	Description
<code>quant_order_n</code>	<code>const MKL_INT*</code>	Pointer to the number of quantile orders
<code>quant_order</code>	<code>const float* for vslsSSEditStreamQuantiles</code> <code>const double* for vsldSSEditStreamQuantiles</code>	Pointer to the array of quantile orders
<code>quants</code>	<code>const float* for vslsSSEditStreamQuantiles</code> <code>const double* for vsldSSEditStreamQuantiles</code>	Pointer to the array of quantiles
<code>nparams</code>	<code>const MKL_INT*</code>	Pointer to the number of the algorithm parameters
<code>params</code>	<code>const float* for vslsSSEditStreamQuantiles</code> <code>const double* for vsldSSEditStreamQuantiles</code>	Pointer to the array of the algorithm parameters

Output Parameters

Name	Type	Description
<code>status</code>	<code>int</code>	Current status of the task

Description

The `vslsSSEditStreamQuantiles` routine replaces pointers to the number of quantile orders, the array of quantile orders, the array of quantiles, the number of the algorithm parameters, and the array of the algorithm parameters with values passed into the routine. If an input parameter is `NULL`, the corresponding parameter in the Summary Statistics task descriptor remains unchanged.

vslsSSEditPooledCovariance

Modifies pooled/group covariance matrix array pointers.

Syntax

```
status = vslsSSEditPooledCovariance(task, grp_indices, pld_mean, pld_cov,
req_grp_indices, grp_means, grp_cov);
```

```
status = vsldSSEditPooledCovariance(task, grp_indices, pld_mean, pld_cov,
req_grp_indices, grp_means, grp_cov);
```

Include Files

- `mk1.h`

Input Parameters

Name	Type	Description
<i>task</i>	VSLSTaskPtr	Descriptor of the task
<i>grp_indices</i>	const MKL_INT*	Pointer to an array of size <i>n</i> . The <i>i</i> -th element of the array contains the number of the group the observation belongs to.
<i>pld_mean</i>	const float* for vslsSSEditPooledCovariance const double* for vsldSSEditPooledCovariance	Pointer to the array of pooled means
<i>pld_cov</i>	const float* for vslsSSEditPooledCovariance const double* for vsldSSEditPooledCovariance	Pointer to the array that holds a pooled covariance matrix
<i>req_grp_indices</i>	const MKL_INT*	Pointer to the array that contains indices of groups for which estimates to return (such as covariance and mean)
<i>grp_means</i>	const float* for vslsSSEditPooledCovariance const double* for vsldSSEditPooledCovariance	Pointer to the array of group means
<i>grp_cov</i>	const float* for vslsSSEditPooledCovariance const double* for vsldSSEditPooledCovariance	Pointer to the array that holds group covariance matrices

Output Parameters

Name	Type	Description
<i>status</i>	int	Current status of the task

Description

The `vslsSSEditPooledCovariance` routine replaces pointers to the array of group indices, the array of pooled means, the array for a pooled covariance matrix, and pointers to the array of indices of group matrices, the array of group means, and the array for group covariance matrices with values passed in the editors. If an input parameter is `NULL`, the corresponding parameter in the Summary Statistics task descriptor remains unchanged. Use the `vslsSSEditTask` routine to replace the storage format for pooled and group covariance matrices.

vslsSSEditRobustCovariance

Modifies pointers to arrays related to a robust covariance matrix.

Syntax

```
status = vslsSSEditRobustCovariance(task, rcov_storage, nparams, params, rmean, rcov);
```

```
status = vsldSSEditRobustCovariance(task, rcov_storage, nparams, params, rmean, rcov);
```

Include Files

- `mk1.h`

Input Parameters

Name	Type	Description
<i>task</i>	VSLSTaskPtr	Descriptor of the task
<i>rcov_storage</i>	const MKL_INT*	Pointer to the storage format of a robust covariance matrix
<i>nparams</i>	const MKL_INT*	Pointer to the number of method parameters
<i>params</i>	const float* for vs1sSEditRobustCovariance const double* for vsldSSEditRobustCovariance	Pointer to the array of method parameters
<i>rmean</i>	const float* for vs1sSEditRobustCovariance const double* for vsldSSEditRobustCovariance	Pointer to the array of robust means
<i>rcov</i>	const float* for vs1sSEditRobustCovariance const double* for vsldSSEditRobustCovariance	Pointer to a robust covariance matrix

Output Parameters

Name	Type	Description
<i>status</i>	int	Current status of the task

Description

The `vs1sSEditRobustCovariance` routine uses values passed as parameters of the routine to replace:

- pointers to covariance matrix storage
- pointers to the number of method parameters and to the array of the method parameters of size *nparams*
- pointers to the arrays that hold robust means and covariance

See [Table "Storage formats of a variance-covariance/correlation matrix"](#) for possible values of the *rcov_storage* parameter. If an input parameter is `NULL`, the corresponding parameter in the task descriptor remains unchanged.

Intel MKL provides a Translated Biweight S-estimator (TBS) for robust estimation of a variance-covariance matrix and mean [Rocke96]. Use one iteration of the Maronna algorithm with the reweighting step [Maronna02] to compute the initial point of the algorithm. Pack the parameters of the TBS algorithm into the *params* array and pass them into the editor. [Table "Structure of the Array of TBS Parameters"](#) describes the *params* structure.

Structure of the Array of TBS Parameters

Array Position	Algorithm Parameter	Description
0	ϵ	Breakdown point, the number of outliers the algorithm can hold. By default, the value is $(n-p) / (2n)$.
1	α	Asymptotic rejection probability, see details in [Rocke96]. By default, the value is 0.001.
2	δ	Stopping criterion: the algorithm is terminated if weights are changed less than δ . By default, the value is 0.001.
3	max_iter	Maximum number of iterations. The algorithm terminates after max_iter iterations. By default, the value is 10. If you set this parameter to zero, the function returns a robust estimate of the variance-covariance matrix computed using the Maronna method [Maronna02] only.

The robust estimator of variance-covariance implementation in Intel MKL requires that the number of observations n be greater than twice the number of variables: $n > 2p$.

See additional details of the algorithm usage model in the *Intel® MKL Summary Statistics Application Notes* document [SS Notes].

vsLSSEditOutliersDetection

Modifies array pointers related to multivariate outliers detection.

Syntax

```
status = vsLSSEditOutliersDetection(task, nparams, params, w);
```

```
status = vsLdSSEditOutliersDetection(task, nparams, params, w);
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
task	VSLSTaskPtr	Descriptor of the task
nparams	const MKL_INT*	Pointer to the number of method parameters
params	const float* for vsLSSEditOutliersDetection const double* for vsLdSSEditOutliersDetection	Pointer to the array of method parameters
w	const float* for vsLSSEditOutliersDetection	Pointer to an array of size n . The array holds the weights of observations to be marked as outliers.

Name	Type	Description
	<code>const double* for vslsSSEditOutliersDetection</code>	

Output Parameters

Name	Type	Description
<code>status</code>	<code>int</code>	Current status of the task

Description

The `vslsSSEditOutliersDetection` routine uses the parameters passed to replace

- the pointers to the number of method parameters and to the array of the method parameters of size `nparams`
- the pointer to the array that holds the calculated weights of the observations

If an input parameter is `NULL`, the corresponding parameter in the task descriptor remains unchanged.

Intel MKL provides the BACON algorithm ([Billor00]) for the detection of multivariate outliers. Pack the parameters of the BACON algorithm into the `params` array and pass them into the editor. [Table "Structure of the Array of BACON Parameters"](#) describes the `params` structure.

Structure of the Array of BACON Parameters

Array Position	Algorithm Parameter	Description
0	Method to start the algorithm	The parameter takes one of the following possible values: <code>VSL_SS_METHOD_BACON_MEDIAN_INIT</code> , if the algorithm is started using the median estimate. This is the default value of the parameter. <code>VSL_SS_METHOD_BACON_MAHALANOBIS_INIT</code> , if the algorithm is started using the Mahalanobis distances.
1	α	One-tailed probability that defines the $(1 - \alpha)$ quantile of χ^2 distribution with <code>p</code> degrees of freedom. The recommended value is α / n , where <code>n</code> is the number of observations. By default, the value is 0.05.
2	δ	Stopping criterion; the algorithm is terminated if the size of the basic subset is changed less than δ . By default, the value is 0.005.

Output of the algorithm is the vector of weights, `BaconWeights`, such that `BaconWeights(i) = 0` if *i*-th observation is detected as an outlier. Otherwise `BaconWeights(i) = w(i)`, where `w` is the vector of input weights. If you do not provide the vector of input weights, `BaconWeights(i)` is set to 1 if the *i*-th observation is not detected as an outlier.

See additional details about usage model of the algorithm in the *Intel(R) MKL Summary Statistics Application Notes* document [SS Notes].

vslSSEditMissingValues

Modifies pointers to arrays associated with the method of supporting missing values in a dataset.

Syntax

```
status = vslsSSEditMissingValues(task, nparams, params, init_estimates_n,
init_estimates, prior_n, prior, simul_missing_vals_n, simul_missing_vals, estimates_n,
estimates);
```

```
status = vsldSSEditMissingValues(task, nparams, params, init_estimates_n,
init_estimates, prior_n, prior, simul_missing_vals_n, simul_missing_vals, estimates_n,
estimates);
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>task</i>	VSLSTaskPtr	Descriptor of the task
<i>nparams</i>	const MKL_INT*	Pointer to the number of method parameters
<i>params</i>	const float* for vslsSSEditMissingValues const double* for vsldSSEditMissingValues	Pointer to the array of method parameters
<i>init_estimates_n</i>	const MKL_INT*	Pointer to the number of initial estimates for mean and a variance-covariance matrix
<i>init_estimates</i>	const float* for vslsSSEditMissingValues const double* for vsldSSEditMissingValues	Pointer to the array that holds initial estimates for mean and a variance-covariance matrix
<i>prior_n</i>	const MKL_INT*	Pointer to the number of prior parameters
<i>prior</i>	const float* for vslsSSEditMissingValues const double* for vsldSSEditMissingValues	Pointer to the array of prior parameters
<i>simul_missing_vals_n</i>	const MKL_INT*	Pointer to the size of the array that holds output of the Multiple Imputation method
<i>simul_missing_vals</i>	const float* for vslsSSEditMissingValues const double* for vsldSSEditMissingValues	Pointer to the array of size $k*m$, where k is the total number of missing values, and m is number of copies of missing values. The array holds m sets of simulated missing values for the matrix of observations.

Name	Type	Description
<i>estimates_n</i>	const MKL_INT*	Pointer to the number of estimates to be returned by the routine
<i>estimates</i>	const float* for vslsSSEditMissingValues const double* for vsldSSEditMissingValues	Pointer to the array that holds estimates of the mean and a variance-covariance matrix.

Output Parameters

Name	Type	Description
<i>status</i>	int	Current status of the task

Description

The `vslsSSEditMissingValues` routine uses values passed as parameters of the routine to replace pointers to the number and the array of the method parameters, pointers to the number and the array of initial mean/variance-covariance estimates, the pointer to the number and the array of prior parameters, pointers to the number and the array of simulated missing values, and pointers to the number and the array of the intermediate mean/covariance estimates. If an input parameter is `NULL`, the corresponding parameter in the task descriptor remains unchanged.

Before you call the Summary Statistics routines to process missing values, preprocess the dataset and denote missing observations with one of the following predefined constants:

- `VSL_SS_SNAN`, if the dataset is stored in single precision floating-point arithmetic
- `VSL_SS_DNAN`, if the dataset is stored in double precision floating-point arithmetic

Intel MKL provides the `VSL_SS_METHOD_MI` method to support missing values in the dataset based on the Multiple Imputation (MI) approach described in [Schafer97]. The following components support Multiple Imputation:

- Expectation Maximization (EM) algorithm to compute the start point for the Data Augmentation (DA) procedure
- DA function

NOTE

The DA component of the MI procedure is simulation-based and uses the `VSL_BRNG_MCG59` basic random number generator with predefined $seed = 2^{50}$ and the Gaussian distribution generator (ICDF method) available in Intel MKL [Gaussian].

Pack the parameters of the MI algorithm into the *params* array. Table "Structure of the Array of MI Parameters" describes the *params* structure.

Structure of the Array of MI Parameters

Array Position	Algorithm Parameter	Description
0	<i>em_iter_num</i>	Maximal number of iterations for the EM algorithm. By default, this value is 50.
1	<i>da_iter_num</i>	Maximal number of iterations for the DA algorithm. By default, this value is 30.

Array Position	Algorithm Parameter	Description
2	ε	Stopping criterion for the EM algorithm. The algorithm terminates if the maximal module of the element-wise difference between the previous and current parameter values is less than ε . By default, this value is 0.001.
3	m	Number of sets to impute
4	<code>missing_vals_num</code>	Total number of missing values in the datasets

You can also pass initial estimates into the EM algorithm by packing both the vector of means and the variance-covariance matrix as a one-dimensional array `init_estimates`. The size of the array should be at least $p + p(p + 1)/2$. For $i=0, \dots, p-1$, the `init_estimates[i]` array contains the initial estimate of means. The remaining positions of the array are occupied by the upper triangular part of the variance-covariance matrix.

If you provide no initial estimates for the EM algorithm, the editor uses the default values, that is, the vector of zero means and the unitary matrix as a variance-covariance matrix. You can also pass `prior` parameters for μ_0 and Σ into the library: μ_0 , τ , m , and Λ^{-1} . Pack these parameters as a one-dimensional array `prior` with a size of at least

$$(p^2 + 3p + 4)/2.$$

The storage format is as follows:

- `prior[0], ..., prior[p-1]` contain the elements of the vector μ_0 .
- `prior[p]` contains the parameter τ .
- `prior[p+1]` contains the parameter m .
- The remaining positions are occupied by the upper-triangular part of the inverted matrix Λ^{-1} .

If you provide no `prior` parameters, the editor uses their default values:

- The array of p zeros is used as μ_0 .
- τ is set to 0.
- m is set to p .
- The zero matrix is used as an initial approximate of Λ^{-1} .

The `EditMissingValues` editor returns m sets of imputed values and/or a sequence of parameter estimates drawn during the DA procedure.

The editor returns the imputed values as the `simul_missing_vals` array. The size of the array should be sufficient to hold m sets each of the `missing_vals_num` size, that is, at least $m \cdot \text{missing\_vals\_num}$ in total. The editor packs the imputed values one by one in the order of their appearance in the matrix of observations.

For example, consider a task of dimension 4. The total number of observations n is 10. The second observation vector misses variables 1 and 2, and the seventh observation vector lacks variable 1. The number of sets to impute is $m=2$. Then, `simul_missing_vals[0]` and `simul_missing_vals[1]` contains the first and the second points for the second observation vector, and `simul_missing_vals[2]` holds the first point for the seventh observation. Positions 3, 4, and 5 are formed similarly.

To estimate convergence of the DA algorithm and choose a proper value of the number of DA iterations, request the sequence of parameter estimates that are produced during the DA procedure. The editor returns the sequence of parameters as a single array. The size of the array is

$$m \cdot \text{da\_iter\_num} \cdot (p + (p^2 + p) / 2)$$

where

- m is the number of sets of values to impute.
- `da_iter_num` is the number of DA iterations.
- The value $p + (p^2 + p) / 2$ determines the size of the memory to hold one set of the parameter estimates.

In each set of the parameters, the vector of means occupies the first p positions and the remaining $(p^2 + p) / 2$ positions are intended for the upper triangular part of the variance-covariance matrix.

Upon successful generation of m sets of imputed values, you can place them in cells of the data matrix with missing values and use the Summary Statistics routines to analyze and get estimates for each of the m complete datasets.

NOTE

Intel MKL implementation of the MI algorithm rewrites cells of the dataset that contain the `VSL_SS_SNAN/VSL_SS_DNAN` values. If you want to use the Summary Statistics routines to process the data with missing values again, mask the positions of the empty cells.

See additional details of the algorithm usage model in the *Intel® MKL Summary Statistics Application Notes* document [SS Notes].

vsLSSEditCorParameterization

Modifies pointers to arrays related to the algorithm of correlation matrix parameterization.

Syntax

```
status = vsLSSEditCorParameterization(task, cor, cor_storage, pcor, pcor_storage);
status = vsLdSSEditCorParameterization(task, cor, cor_storage, pcor, pcor_storage);
```

Include Files

- `mkl.h`

Input Parameters

Name	Type	Description
<code>task</code>	<code>VSLSSTaskPtr</code>	Descriptor of the task
<code>cor</code>	<code>const float*</code> for <code>vsLSSEditCorParameterization</code> <code>const double*</code> for <code>vsLdSSEditCorParameterization</code>	Pointer to the correlation matrix
<code>cor_storage</code>	<code>const MKL_INT*</code>	Pointer to the storage format of the correlation matrix
<code>pcor</code>	<code>const float*</code> for <code>vsLSSEditCorParameterization</code> <code>const double*</code> for <code>vsLdSSEditCorParameterization</code>	Pointer to the parameterized correlation matrix
<code>por_storage</code>	<code>const MKL_INT*</code>	Pointer to the storage format of the parameterized correlation matrix

Output Parameters

Name	Type	Description
<i>status</i>	int	Current status of the task

Description

The `vs1SSEditCorParameterization` routine uses values passed as parameters of the routine to replace pointers to the correlation matrix, pointers to the correlation matrix storage format, a pointer to the parameterized correlation matrix, and a pointer to the parameterized correlation matrix storage format. See [Table "Storage formats of a variance-covariance/correlation matrix"](#) for possible values of the `cor_storage` and `pcor_storage` parameters. If an input parameter is `NULL`, the corresponding parameter in the Summary Statistics task descriptor remains unchanged.

Task Computation Routines

Task computation routines calculate statistical estimates on the data provided and parameters held in the task descriptor. After you create the task and initialize its parameters, you can call the computation routines as many times as necessary. [Table "Summary Statistics Estimates Obtained with vs1SSCompute Routine"](#) lists the statistical estimates that you can obtain using the `vs1SSCompute` routine.

NOTE

The Summary Statistics computation routines do not signal floating-point errors, such as overflow or gradual underflow, or operations with NaNs (except for the missing values in the observations).

Summary Statistics Estimates Obtained with vs1SSCompute Routine

Estimate	Support of Observations Available in Blocks	Description
VSL_SS_MEAN	Yes	Computes the array of means.
VSL_SS_SUM	Yes	Computes the array of sums.
VSL_SS_2R_MOM	Yes	Computes the array of the 2 nd order raw moments.
VSL_SS_2R_SUM	Yes	Computes the array of raw sums of the 2 nd order.
VSL_SS_3R_MOM	Yes	Computes the array of the 3 rd order raw moments.
VSL_SS_3R_SUM	Yes	Computes the array of raw sums of the 3 rd order.
VSL_SS_4R_MOM	Yes	Computes the array of the 4 th order raw moments.
VSL_SS_4R_SUM	Yes	Computes the array of raw sums of the 4 th order.
VSL_SS_2C_MOM	Yes	Computes the array of the 2 nd order central moments.
VSL_SS_2C_SUM	Yes	Computes the array of central sums of the 2 nd order.

Estimate	Support of Observations Available in Blocks	Description
VSL_SS_3C_MOM	Yes	Computes the array of the 3 rd order central moments.
VSL_SS_3C_SUM	Yes	Computes the array of central sums of the 3 rd order.
VSL_SS_4C_MOM	Yes	Computes the array of the 4 th order central moments.
VSL_SS_4C_SUM	Yes	Computes the array of central sums of the 4 th order.
VSL_SS_KURTOSIS	Yes	Computes the array of kurtosis values.
VSL_SS_SKEWNESS	Yes	Computes the array of skewness values.
VSL_SS_MIN	Yes	Computes the array of minimum values.
VSL_SS_MAX	Yes	Computes the array of maximum values.
VSL_SS_VARIATION	Yes	Computes the array of variation coefficients.
VSL_SS_COV	Yes	Computes a covariance matrix.
VSL_SS_COR	Yes	Computes a correlation matrix. The main diagonal of the correlation matrix holds variances of the random vector components.
VSL_SS_CP	Yes	Computes a cross-product matrix.
VSL_SS_POOLED_COV	No	Computes a pooled covariance matrix.
VSL_SS_POOLED_MEAN	No	Computes an array of pooled means.
VSL_SS_GROUP_COV	No	Computes group covariance matrices.
VSL_SS_GROUP_MEAN	No	Computes group means.
VSL_SS_QUANTS	No	Computes quantiles.
VSL_SS_ORDER_STATS	No	Computes order statistics.
VSL_SS_ROBUST_COV	No	Computes a robust covariance matrix.
VSL_SS_OUTLIERS	No	Detects outliers in the dataset.
VSL_SS_PARTIAL_COV	No	Computes a partial covariance matrix.
VSL_SS_PARTIAL_COR	No	Computes a partial correlation matrix.
VSL_SS_MISSING_VALS	No	Supports missing values in datasets.
VSL_SS_PARAMTR_COR	No	Computes a parameterized correlation matrix.
VSL_SS_STREAM_QUANTS	Yes	Computes quantiles for streaming data.
VSL_SS_MDAD	No	Computes median absolute deviation.
VSL_SS_MNAD	No	Computes mean absolute deviation.
VSL_SS_SORTED_OBSERV	No	Sorts the dataset by the components of the random vector ξ .

Table "Summary Statistics Computation Method" lists estimate calculation methods supported by Intel MKL. See the *Intel(R) MKL Summary Statistics Application Notes* document [[SS Notes](#)] for a detailed description of the methods.

Summary Statistics Computation Method

Method	Description
VSL_SS_METHOD_FAST	Fast method for calculation of the estimates: - raw/central moments/sums, skewness, kurtosis, variation, variance-covariance/correlation/cross-product matrix - min/max/quantile/order statistics - partial variance-covariance - median/mean absolute deviation
VSL_SS_METHOD_FAST_USER_MEAN	Fast method for calculation of the estimates given user-defined mean: central moments/sums of 2-4 order, skewness, kurtosis, variation, variance-covariance/correlation/cross-product matrix, mean absolute deviation
VSL_SS_METHOD_1PASS	One-pass method for calculation of estimates: - raw/central moments/sums, skewness, kurtosis, variation, variance-covariance/correlation/cross-product matrix - pooled/group covariance matrix
VSL_SS_METHOD_TBS	TBS method for robust estimation of covariance and mean
VSL_SS_METHOD_BACON	BACON method for detection of multivariate outliers
VSL_SS_METHOD_MI	Multiple imputation method for support of missing values
VSL_SS_METHOD_SD	Spectral decomposition method for parameterization of a correlation matrix
VSL_SS_METHOD_SQUANTS_ZW	Zhang-Wang (ZW) method for quantile estimation for streaming data
VSL_SS_METHOD_SQUANTS_ZW_FAST	Fast ZW method for quantile estimation for streaming data
VSL_SS_METHOD_RADIX	Radix method for dataset sorting

You can calculate all requested estimates in one call of the routine. For example, to compute a kurtosis and covariance matrix using a fast method, pass a combination of the pre-defined parameters into the `Compute` routine as shown in the example below:

```
...
method = VSL_SS_METHOD_FAST;
task_params = VSL_SS_KURTOSIS|VSL_SS_COV;
...
status = vsldSSCompute( task, task_params, method );
```

To compute statistical estimates for the next block of observations, you can do one of the following:

- copy the observations to memory, starting with the address available to the task
- use one of the appropriate [Editors](#) to modify the pointer to the new dataset in the task.

The library does not detect your changes of the dataset and computed statistical estimates. To obtain statistical estimates for a new matrix, change the observations and initialize relevant arrays. You can follow this procedure to compute statistical estimates for observations that come in portions. See [Table "Summary Statistics Estimates Obtained with `vs1SSCompute` Routine"](#) for information on such observations supported by the Intel MKL Summary Statistics estimators.

To modify parameters of the task using the Task Editors, set the address of the targeted matrix of the observations or change the respective vector component indices. After you complete editing the task parameters, you can compute statistical estimates in the modified environment.

If the task completes successfully, the computation routine returns the zero status code. If an error is detected, the computation routine returns an error code. In particular, an error status code is returned in the following cases:

- the task pointer is `NULL`
- memory allocation has failed
- the calculation has failed for some other reason

NOTE

You can use the `NULL` task pointer in calls to editor routines. In this case, the routine is terminated and no system crash occurs.

vs1SSCompute

Computes Summary Statistics estimates.

Syntax

```
status = vs1sSSCompute(task, estimates, method);
```

```
status = vs1dSSCompute(task, estimates, method);
```

Include Files

- `mk1.h`

Input Parameters

Name	Type	Description
<code>task</code>	<code>VSLSSTaskPtr</code>	Descriptor of the task
<code>estimates</code>	<code>const MKL_INT64</code>	List of statistical estimates to compute
<code>method</code>	<code>const MKL_INT</code>	Method to be used in calculations

Output Parameters

Name	Type	Description
<code>status</code>	<code>int</code>	Current status of the task

Description

The `vs1SSCompute` routine calculates statistical estimates passed as the `estimates` parameter using the algorithms passed as the `method` parameter of the routine. The computations are done in the context of the task descriptor that contains pointers to all required and optional, if necessary, properly initialized arrays. In one call of the function, you can compute several estimates using proper methods for their calculation. See [Table "Summary Statistics Estimates Obtained with `Compute` Routine"](#) for the list of the estimates that you can calculate with the `vs1SSCompute` routine. See [Table "Summary Statistics Computation Methods"](#) for the list of possible values of the `method` parameter.

To initialize single or double precision version task parameters, use the single (`vslsscompute`) or double (`vslsdsscompute`) version of the editor, respectively. To initialize parameters of the integer type, use an integer version of the editor (`vslisscompute`).

NOTE

Requesting a combination of the `VSL_SS_MISSING_VALS` value and any other estimate parameter in the `Compute` function results in processing only the missing values.

Application Notes

Be aware that when computing a correlation matrix, the `vslSSCompute` routine allocates an additional array for each thread which is running the task. If you are running on a large number of threads `vslSSCompute` might consume large amounts of memory.

When calculating covariance, correlation, or cross product, the number of bytes of memory required is at least $(P*P*T + P*T)*b$, where P is the dimension of the task or number of variables, T is the number of threads, and b is the number of bytes required for each unit of data. If observation is weighted and the method is `VSL_SS_METHOD_FAST`, then the memory required is at least $(P*P*T + P*T + N*P)*b$, where N is the number of observations.

Task Destructor

Task destructor is the `vslSSDeleteTask` routine intended to delete task objects and release memory.

`vslSSDeleteTask`

Destroys the task object and releases the memory.

Syntax

```
status = vslSSDeleteTask(&task);
```

Include Files

- `mkl.h`

Input Parameters

Name	Type	Description
<code>task</code>	<code>VSLSSTaskPtr*</code>	Descriptor of the task to destroy

Output Parameters

Name	Type	Description
<code>status</code>	<code>int</code>	Sets to <code>VSL_STATUS_OK</code> if the task is deleted; otherwise a non-zero code is returned.

Description

The `vslSSDeleteTask` routine deletes the task descriptor object, releases the memory allocated for the structure, and sets the task pointer to `NULL`. If `vslSSDeleteTask` fails to delete the task successfully, it returns an error code.

NOTE

Call of the destructor with the `NULL` pointer as the parameter results in termination of the function with no system crash.

Usage Examples

The following examples show various standard operations with Summary Statistics routines.

Calculating Fixed Estimates for Fixed Data

The example shows recurrent calculation of the same estimates with a given set of variables for the complete life cycle of the task in the case of a variance-covariance matrix. The set of vector components to process remains unchanged, and the data comes in blocks. Before you call the `vs1SSCompute` routine, initialize pointers to arrays for mean and covariance and set buffers.

```
...
double w[2];
double indices[DIM] = {1, 0, 1};

/* calculating mean for 1st and 3d random vector components */

/* Initialize parameters of the task */
p = DIM;
n = N;

xstorage = VSL_SS_MATRIX_STORAGE_ROWS;
covstorage = VSL_SS_MATRIX_STORAGE_FULL;

w[0] = 0.0; w[1] = 0.0;

for ( i = 0; i < p; i++ ) mean[i] = 0.0;
for ( i = 0; i < p*p; i++ ) cov[i] = 0.0;

status = vsldSSNewTask( &task, &p, &n, &xstorage, x, 0, indices );

status = vsldSSEditTask ( task, VSL_SS_ED_ACCUM_WEIGHT, w );
status = vsldSSEditCovCor( task, mean, cov, &covstorage, 0, 0 );
```

You can process data arrays that come in blocks as follows:

```
for ( i = 0; i < num_of_blocks; i++ )
{
    status = vsldSSCompute( task, VSL_SS_COV, VSL_SS_METHOD_FAST );
    /* Read new data block into array x */
}
...
```

Calculating Different Estimates for Variable Data

The context of your calculation may change in the process of data analysis. The example below shows the data that comes in two blocks. You need to estimate a covariance matrix for the complete data, and the third central moment for the second block of the data using the weights that were accumulated for the previous datasets. The second block of the data is stored in another array. You can proceed as follows:

```
/* Set parameters for the task */
p = DIM;
n = N;
xstorage = VSL_SS_MATRIX_STORAGE_ROWS;
covstorage = VSL_SS_MATRIX_STORAGE_FULL;
```

```
w[0] = 0.0; w[1] = 0.0;

for ( i = 0; i < p; i++ ) mean[i] = 0.0;
for ( i = 0; i < p*p; i++ ) cov[i] = 0.0;

/* Create task */
status = vsldSSNewTask( &task, &p, &n, &xstorage, x1, 0, indices );

/* Initialize the task parameters */
status = vsldSSEditTask( task, VSL_SS_ED_ACCUM_WEIGHT, w );
status = vsldSSEditCovCor( task, mean, cov, &covstorage, 0, 0 );

/* Calculate covariance for the x1 data */
status = vsldSSCompute( task, VSL_SS_COV, VSL_SS_METHOD_FAST );

/* Initialize array of the 3d central moments and pass the pointer to the task */
for ( i = 0; i < p; i++ ) c3_m[i] = 0.0;

/* Modify task context */
status = vsldSSEditTask( task, VSL_SS_ED_3C_MOM, c3_m );
status = vsldSSEditTask( task, VSL_SS_ED_OBSERV, x2 );

/* Calculate covariance for the x1 & x2 data block */
/* Calculate the 3d central moment for the 2nd data block using earlier accumulated weight */
status = vsldSSCompute(task, VSL_SS_COV|VSL_SS_3C_MOM, VSL_SS_METHOD_FAST );
...
status = vsldSSDeleteTask( &task );
```

Similarly, you can modify indices of the variables to be processed for the next data block.

Mathematical Notation and Definitions

The following notations are used in the mathematical definitions and the description of the Intel MKL Summary Statistics functions.

Matrix and Weights of Observations

For a random p -dimensional vector $\xi = (\xi_1, \dots, \xi_i, \dots, \xi_p)$, this manual denotes the following:

- $(X)_i = (x_{ij})_{j=1..n}$ is the result of n independent observations for the i -th component ξ_i of the vector ξ .
- The two-dimensional array $X = (x_{ij})_{p \times n}$ is the matrix of observations.
- The column $[X]_j = (x_{ij})_{i=1..p}$ of the matrix X is the j -th observation of the random vector ξ .

Each observation $[X]_j$ is assigned a non-negative weight w_j , where

- The vector $(w_j)_{j=1..n}$ is a vector of weights corresponding to n observations of the random vector ξ .
- $$W = \sum_{i=1}^n w_i$$

is the accumulated weight corresponding to observations X .

Vector of sample means

$$M(X) = (M_1(X), \dots, M_p(X)) \text{ with } M_i(X) = \frac{1}{W} \sum_{j=1}^n w_j x_{ij}$$

for all $i = 1, \dots, p$.

Vector of sample partial sums

$$S(X) = (S_1(X), \dots, S_p(X)) \text{ with } S_i(X) = \sum_{j=1}^n w_j x_{ij}$$

for all $i = 1, \dots, p$.

Vector of sample variances

$$V(X) = (V_1(X), \dots, V_p(X)) \text{ with } V_i(X) = \frac{1}{B} \sum_{j=1}^n w_j (x_{ij} - M_i(X))^2, B = W - \sum_{j=1}^n w_j^2 / W$$

for all $i = 1, \dots, p$.

Vector of sample raw/algebraic moments of k -th order, $k \geq 1$

$$R^{(k)}(X) = (R_1^{(k)}(X), \dots, R_p^{(k)}(X)) \text{ with } R_i^{(k)}(X) = \frac{1}{W} \sum_{j=1}^n w_j x_{ij}^k$$

for all $i = 1, \dots, p$.

Vector of sample raw/algebraic partial sums of k -th order, $k = 2, 3, 4$ (raw/algebraic partial sums of squares/cubes/fourth powers)

$$S^k(X) = (S_1^k(X), \dots, S_p^k(X)) \text{ with } S_i^k(X) = \sum_{j=1}^n w_j x_{ij}^k$$

for all $i = 1, \dots, p$.

Vector of sample central moments of the third and the fourth order

$$C^{(k)}(X) = (C_1^{(k)}(X), \dots, C_p^{(k)}(X)) \text{ with } C_i^{(k)}(X) = \frac{1}{B} \sum_{j=1}^n w_j (x_{ij} - M_i(X))^k, B = \sum_{j=1}^n w_j$$

for all $i = 1, \dots, p$ and $k = 3, 4$.

Vector of sample central partial sums of k -th order, $k = 2, 3, 4$ (central partial sums of squares/cubes/fourth powers)

$$S^k(X) = (S_1^k(X), \dots, S_p^k(X)) \text{ with } S_i^k(X) = \sum_{j=1}^n w_j (x_{ij} - S_i(X))^k$$

for all $i = 1, \dots, p$.

Vector of sample excess kurtosis values

$$B(X) = (B_1(X), \dots, B_p(X)) \text{ with } B_i(X) = \frac{C_i^{(4)}(X)}{V_i^2(X)} - 3$$

for all $i = 1, \dots, p$.

Vector of sample skewness values

$$\Gamma(X) = (\Gamma_1(X), \dots, \Gamma_p(X)) \text{ with } \Gamma_i(X) = \frac{C_i^{(3)}(X)}{V_i^{1.5}(X)}$$

for all $i = 1, \dots, p$.

Vector of sample variation coefficients

$$VC(X) = (VC_1(X), \dots, VC_p(X)) \text{ with } VC_i(X) = \frac{V_i^{0.5}(X)}{M_i(X)}$$

for all $i = 1, \dots, p$.

Matrix of order statistics

Matrix $Y = (Y_{ij})_{p \times n}$, in which the i -th row $(Y)_i = (Y_{ij})_{j=1..n}$ is obtained as a result of sorting in the ascending order of row $(X)_i = (X_{ij})_{j=1..n}$ in the original matrix of observations.

Vector of sample minimum values

$$Min(X) = (Min_1(X), \dots, Min_p(X)), \text{ where } Min_i(X) = y_{i1}$$

for all $i = 1, \dots, p$.

Vector of sample maximum values

$$Max(X) = (Max_1(X), \dots, Max_p(X)), \text{ where } Max_i(X) = y_{in}$$

for all $i = 1, \dots, p$.

Vector of sample median values

$$Med(X) = (Med_1(X), \dots, Med_p(X)), \text{ where } Med_i(X) = \begin{cases} y_{i,(n+1)/2}, & \text{if } n \text{ is odd} \\ (y_{i,n/2} + y_{i,n/2+1}) / 2, & \text{if } n \text{ is even} \end{cases}$$

for all $i = 1, \dots, p$.

Vector of sample median absolute deviations

$$MDAD(X) = (MDAD_1(X), \dots, MDAD_p(X)), \text{ where } MDAD_i(X) = Med_i(Z) \text{ with } Z = (z_{ij})_{i=1..p, j=1..n},$$

$$z_{ij} = |x_{ij} - Med_i(X)|$$

for all $i = 1, \dots, p$.

Vector of sample mean absolute deviations

$$MNAD(X) = (MNAD_1(X), \dots, MNAD_p(X)), \text{ where } MNAD_i(X) = M_i(Z) \text{ with } Z = (z_{ij})_{i=1..p, j=1..n}, z_{ij} = |x_{ij} - M_i(X)|$$

for all $i = 1, \dots, p$.

Vector of sample quantile values

For a positive integer number q and k belonging to the interval $[0, q-1]$, point z_i is the k -th q quantile of the random variable ξ_i if $P\{\xi_i \leq z_i\} \geq \beta$ and $P\{\xi_i \leq z_i\} \geq 1 - \beta$, where

- P is the probability measure.
- $\beta = k/q$ is the quantile order.

The calculation of quantiles is as follows:

$j = [(n-1)\beta]$ and $f = \{(n-1)\beta\}$ as integer and fractional parts of the number $(n-1)\beta$, respectively, and the vector of sample quantile values is

$$Q(X, \beta) = (Q_1(X, \beta), \dots, Q_p(X, \beta))$$

where

$$(Q_i(X, \beta) = y_{i,j+1} + f(y_{i,j+2} - y_{i,j+1}))$$

for all $i = 1, \dots, p$.

Variance-covariance matrix

$$C(X) = (c_{ij}(X))_{p \times p}$$

where

$$c_{ij}(X) = \frac{1}{B} \sum_{k=1}^n w_k (x_{ik} - M_i(X))(x_{jk} - M_j(X)), \quad B = W - \sum_{j=1}^n w_j^2 / W$$

Cross-product matrix (matrix of cross-products and sums of squares)

$$CP(X) = (cp_{ij}(X))_{p \times p}$$

where

$$cp_{ij}(X) = \sum_{k=1}^n w_k (x_{ik} - M_i(X))(x_{jk} - M_j(X))$$

Pooled and group variance-covariance matrices

The set $N = \{1, \dots, n\}$ is partitioned into non-intersecting subsets

$$G_i, \quad i = 1..g, \quad N = \bigcup_{i=1}^g G_i$$

The observation $[X]_j = (x_{ij})_{i=1..p}$ belongs to the group r if $j \in G_r$. One observation belongs to one group only. The group mean and variance-covariance matrices are calculated similarly to the formulas above:

$$M^{(r)}(X) = (M_1^{(r)}(X), \dots, M_p^{(r)}(X)) \text{ with } M_i^{(r)}(X) = \frac{1}{W^{(r)}} \sum_{j \in G_r} w_j x_{ij}, \quad W^{(r)} = \sum_{j \in G_r} w_j$$

for all $i = 1, \dots, p$,

$$C^{(r)}(X) = (c_{ij}^{(r)}(X))_{p \times p}$$

where

$$c_{ij}^{(r)}(X) = \frac{1}{B^{(r)}} \sum_{k \in G_r} w_k (x_{ik} - M_i^{(r)}(X))(x_{jk} - M_j^{(r)}(X)), \quad B^{(r)} = W^{(r)} - \sum_{j \in G_r} w_j^2 / W^{(r)}$$

for all $i = 1, \dots, p$ and $j = 1, \dots, p$.

A pooled variance-covariance matrix and a pooled mean are computed as weighted mean over group covariance matrices and group means, correspondingly:

$$M^{pooled}(X) = (M_1^{pooled}(X), \dots, M_p^{pooled}(X)) \text{ with } M_i^{pooled}(X) = \frac{1}{W^{(1)} + \dots + W^{(g)}} \sum_{r=1}^g W^{(r)} M_i^{(r)}(X)$$

for all $i = 1, \dots, p$,

$$C^{pooled}(X) = (c_{ij}^{pooled}(X))_{p \times p}, \quad c_{ij}^{pooled}(X) = \frac{1}{B^{(1)} + \dots + B^{(g)}} \sum_{r=1}^g B^{(r)} c_{ij}^{(r)}(X)$$

for all $i = 1, \dots, p$ and $j = 1, \dots, p$.

Correlation matrix

$$R(X) = (r_{ij}(X))_{p \times p}, \text{ where } r_{ij}(X) = \frac{c_{ij}}{\sqrt{c_{ii} c_{jj}}}$$

for all $i = 1, \dots, p$ and $j = 1, \dots, p$.

Partial variance-covariance matrix

For a random vector ξ partitioned into two components Z and Y , a variance-covariance matrix C describes the structure of dependencies in the vector ξ :

$$C(X) = \begin{pmatrix} C_Z(X) & C_{ZY}(X) \\ C_{YZ}(X) & C_Y(X) \end{pmatrix}.$$

The partial covariance matrix $P(X) = (p_{ij}(X))_{k \times k}$ is defined as

$$P(X) = C_Y(X) - C_{YZ}(X)C_Z^{-1}C_{ZY}(X).$$

where k is the dimension of Y .

Partial correlation matrix

The following is a partial correlation matrix for all $i = 1, \dots, k$ and $j = 1, \dots, k$:

$$RP(X) = (rp_{ij}(X))_{k \times k}, \text{ where } rp_{ij}(X) = \frac{p_{ij}(X)}{\sqrt{p_{ii}(X)p_{jj}(X)}}$$

where

- k is the dimension of Y .
- $p_{ij}(X)$ are elements of the partial variance-covariance matrix.

Sorted dataset

Matrix $Y = (y_{ij})_{p \times n}$, in which the i -th row $(Y)_i$ is obtained as a result of sorting in ascending order the row $(X)_i = (x_{ij})_{j=1..n}$ in the original matrix of observations.

Fourier Transform Functions

The general form of the discrete Fourier transform is

$$z_{k_1, k_2, \dots, k_d} = \sigma \times \sum_{j_d=0}^{n_d-1} \dots \sum_{j_2=0}^{n_2-1} \sum_{j_1=0}^{n_1-1} w_{j_1 j_2 \dots j_d} \exp \left(\delta i 2\pi \sum_{l=1}^d j_l k_l / n_l \right)$$

for $k_l = 0, \dots, n_l-1$ ($l = 1, \dots, d$), where σ is a scale factor, $\delta = -1$ for the forward transform, and $\delta = +1$ for the inverse (backward) transform. In the forward transform, the input (periodic) sequence $\{w_{j_1, j_2, \dots, j_d}\}$ belongs to the set of complex-valued sequences and real-valued sequences. Respective domains for the backward transform are represented by complex-valued sequences and complex-valued conjugate-even sequences.

The Intel® Math Kernel Library (Intel® MKL) provides an interface for computing a discrete Fourier transform through the fast Fourier transform algorithm. Prefixes `Dfti` in function names and `DFTI` in the names of configuration parameters stand for Discrete Fourier Transform Interface.

This chapter describes the following implementations of the fast Fourier transform functions available in Intel MKL:

- Fast Fourier transform (FFT) functions for single-processor or shared-memory systems (see [FFT Functions](#))
- [Cluster FFT functions](#) for distributed-memory architectures (available only for Intel® 64 and Intel® Many Integrated Core architectures)

NOTE

Intel MKL also supports the FFTW3* interfaces to the fast Fourier transform functionality for shared memory paradigm (SMP) systems.

Both FFT and Cluster FFT functions compute an FFT in five steps:

1. Allocate a fresh descriptor for the problem with a call to the `DftiCreateDescriptor` or `DftiCreateDescriptorDM` function. The descriptor captures the configuration of the transform, such as the dimensionality (or rank), sizes, number of transforms, memory layout of the input/output data (defined by strides), and scaling factors. Many of the configuration settings are assigned default values in this call which you might need to modify in your application.
2. Optionally adjust the descriptor configuration with a call to the `DftiSetValue` or `DftiSetValueDM` function as needed. Typically, you must carefully define the data storage layout for an FFT or the data distribution among processes for a Cluster FFT. The configuration settings of the descriptor, such as the default values, can be obtained with the `DftiGetValue` or `DftiGetValueDM` function.
3. Commit the descriptor with a call to the `DftiCommitDescriptor` or `DftiCommitDescriptorDM` function, that is, make the descriptor ready for the transform computation. Once the descriptor is committed, the parameters of the transform, such as the type and number of transforms, strides and distances, the type and storage layout of the data, and so on, are "frozen" in the descriptor.
4. Compute the transform with a call to the `DftiComputeForward`/`DftiComputeBackward` or `DftiComputeForwardDM`/`DftiComputeBackwardDM` functions as many times as needed. Because the descriptor is defined and committed separately, all that the compute functions do is take the input and output data and compute the transform as defined. To modify any configuration parameters for another call to a compute function, use `DftiSetValue` followed by `DftiCommitDescriptor` (`DftiSetValueDM` followed by `DftiCommitDescriptorDM`) or create and commit another descriptor.
5. Deallocate the descriptor with a call to the `DftiFreeDescriptor` or `DftiFreeDescriptorDM` function. This returns the memory internally consumed by the descriptor to the operating system.

All the above functions return an integer status value, which is zero upon successful completion of the operation. You can interpret a non-zero status with the help of the [DftiErrorClass](#) or [DftiErrorMessage](#) function.

The FFT functions support lengths with arbitrary factors. You can improve performance of the Intel MKL FFT if the length of your data vector permits factorization into powers of optimized radices. See the *Intel MKL User's Guide* for specific radices supported efficiently.

NOTE

The FFT functions assume the Cartesian representation of complex data (that is, the real and imaginary parts define a complex number). The Intel MKL Vector Mathematical Functions provide efficient tools for conversion to and from polar representation (see [Example "Conversion from Cartesian to polar representation of complex data"](#) and [Example "Conversion from polar to Cartesian representation of complex data"](#)).

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

FFT Functions

The fast Fourier transform function library of Intel MKL provides one-dimensional, two-dimensional, and multi-dimensional transforms (of up to seven dimensions) and offers both Fortran and C interfaces for all transform functions.

Table "FFT Functions in Intel MKL" lists FFT functions implemented in Intel MKL:

FFT Functions in Intel MKL

Function Name	Operation
Descriptor Manipulation Functions	
DftiCreateDescriptor	Allocates the descriptor data structure and initializes it with default configuration values.
DftiCommitDescriptor	Performs all initialization for the actual FFT computation.
DftiFreeDescriptor	Frees memory allocated for a descriptor.
DftiCopyDescriptor	Makes a copy of an existing descriptor.
FFT Computation Functions	
DftiComputeForward	Computes the forward FFT.
DftiComputeBackward	Computes the backward FFT.
Descriptor Configuration Functions	
DftiSetValue	Sets one particular configuration parameter with the specified configuration value.
DftiGetValue	Gets the value of one particular configuration parameter.

Function Name	Operation
Status Checking Functions	
<code>DftiErrorClass</code>	Checks if the status reflects an error of a predefined class.
<code>DftiErrorMessage</code>	Translates the numeric value of an error status into a message.

FFT Interface

The Intel MKL FFT functions are provided with the Fortran and C interfaces.

The materials presented in this chapter assume the availability of native complex types in C as they are specified in C9X.

To use the FFT functions, you need to include `mkl_dfti.h` in your C code.

The C interface provides the `DFTI_DESCRIPTOR_HANDLE` type, named constants of two enumeration types `DFTI_CONFIG_PARAM` and `DFTI_CONFIG_VALUE`, and functions, some of which accept different numbers of input arguments.

NOTE

The current version of the library may not support some of the FFT functions or functionality described in the subsequent sections of this chapter. You can find the complete list of the implementation-specific exceptions in the Intel MKL Release Notes.

For the main categories of Intel MKL FFT functions, see [FFT Functions](#).

Computing an FFT

You can find code examples that compute transforms in the [Fourier Transform Functions Code Examples](#) section in the Code Examples appendix.

Usually you can compute an FFT by five function calls (refer to the [usage model](#) for details). A single data structure, the descriptor, stores configuration parameters that can be changed independently.

The descriptor data structure, when created, contains information about the length and domain of the FFT to be computed, as well as the setting of several configuration parameters. Default settings for some of these parameters are as follows:

- Scale factor: none
- Number of data sets: one
- Data storage: contiguous
- Placement of results: in-place (the computed result overwrites the input data)

The default settings can be changed one at a time through the function `DftiSetValue` as illustrated in [Example "Changing Default Settings \(C\)"](#).

Configuration Settings

Each of the configuration parameters is identified by a named constant in the `MKL_DFTI` module. These named constants have the enumeration type `DFTI_CONFIG_PARAM`.

All the Intel MKL FFT configuration parameters are readable. Some of them are read-only, while others can be set using the `DftiCreateDescriptor` or `DftiSetValue` function.

Values of the configuration parameters fall into the following groups:

- Values that have native data types. For example, the number of simultaneous transforms requested has an integer value, while the scale factor for a forward transform is a single-precision number.

- Values that are discrete in nature and are provided in the `MKL_DFTI` module as named constants. For example, the domain of the forward transform requires values to be named constants. The named constants for configuration values have the enumeration type `DFTI_CONFIG_VALUE`.

Table "Configuration Parameters" summarises the information on configuration parameters, along with their types and values. For more details of each configuration parameter, see the subsection describing this parameter.

Configuration Parameters

Configuration Parameter	Type/Value	Comments
<i>Most common configuration parameters, no default, must be set explicitly by <code>DftiCreateDescriptor</code></i>		
<code>DFTI_PRECISION</code>	Named constant <code>DFTI_SINGLE</code> or <code>DFTI_DOUBLE</code>	Precision of the computation.
<code>DFTI_FORWARD_DOMAIN</code>	Named constant <code>DFTI_COMPLEX</code> or <code>DFTI_REAL</code>	Type of the transform.
<code>DFTI_DIMENSION</code>	Integer scalar	Dimension of the transform.
<code>DFTI_LENGTH</code>	Integer scalar/array	Lengths of each dimension.
<i>Common configuration parameters, settable by <code>DftiSetValue</code></i>		
<code>DFTI_PLACEMENT</code>	Named constant <code>DFTI_INPLACE</code> or <code>DFTI_NOT_INPLACE</code>	Defines whether the result overwrites the input data. Default value: <code>DFTI_INPLACE</code> .
<code>DFTI_FORWARD_SCALE</code>	Floating-point scalar	Scale factor for the forward transform. Default value: 1.0. Precision of the value should be the same as defined by <code>DFTI_PRECISION</code> .
<code>DFTI_BACKWARD_SCALE</code>	Floating-point scalar	Scale factor for the backward transform. Default value: 1.0. Precision of the value should be the same as defined by <code>DFTI_PRECISION</code> .
<code>DFTI_NUMBER_OF_USER_THREADS</code>	Integer scalar	This configuration parameter is no longer used and kept for compatibility with previous versions of Intel MKL.
<code>DFTI_THREAD_LIMIT</code>	Integer scalar	Limits the number of threads for the DftiComputeForward and DftiComputeBackward . Default value: 0.
<code>DFTI_DESCRIPTOR_NAME</code>	Character string	Assigns a name to a descriptor. Assumed length of the string is <code>DFTI_MAX_NAME_LENGTH</code> . Default value: empty string.
<i>Data layout configuration parameters for single and multiple transforms. Settable by <code>DftiSetValue</code></i>		
<code>DFTI_INPUT_STRIDES</code>	Integer array	Defines the input data layout.
<code>DFTI_OUTPUT_STRIDES</code>	Integer array	Defines the output data layout.
<code>DFTI_NUMBER_OF_TRANSFORMS</code>	Integer scalar	Number of transforms.

Configuration Parameter	Type/Value	Comments
		Default value: 1.
<code>DFTI_INPUT_DISTANCE</code>	Integer scalar	Defines the distance between input data sets for multiple transforms.
		Default value: 0.
<code>DFTI_OUTPUT_DISTANCE</code>	Integer scalar	Defines the distance between output data sets for multiple transforms.
		Default value: 0.
<code>DFTI_COMPLEX_STORAGE</code>	Named constant <code>DFTI_COMPLEX_COMPLEX</code> or <code>DFTI_REAL_REAL</code>	Defines whether the real and imaginary parts of data for a complex transform are interleaved in one array or split in two arrays.
		Default value: <code>DFTI_COMPLEX_COMPLEX</code> .
<code>DFTI_REAL_STORAGE</code>	Named constant <code>DFTI_REAL_REAL</code>	Defines how real data for a real transform is stored. Only the <code>DFTI_REAL_REAL</code> value is supported.
<code>DFTI_CONJUGATE_EVEN_STORAGE</code>	Named constant <code>DFTI_COMPLEX_COMPLEX</code> or <code>DFTI_COMPLEX_REAL</code>	Defines whether the complex data in the backward domain of a real transform is stored as complex elements or as real elements.
		For the default value, see the detailed description.
<code>DFTI_PACKED_FORMAT</code>	Named constant <code>DFTI_CCE_FORMAT</code> , <code>DFTI_CCS_FORMAT</code> , <code>DFTI_PACK_FORMAT</code> , or <code>DFTI_PERM_FORMAT</code>	Defines the layout of real elements in the backward domain of a one-dimensional or two-dimensional real transform.
<i>Advanced configuration parameters, settable by <code>DftiSetValue</code></i>		
<code>DFTI_WORKSPACE</code>	Named constant <code>DFTI_ALLOW</code> or <code>DFTI_AVOID</code>	Defines whether the library should prefer algorithms using additional memory.
		Default value: <code>DFTI_ALLOW</code> .
<code>DFTI_ORDERING</code>	Named constant <code>DFTI_ORDERED</code> or <code>DFTI_BACKWARD_SCRAMBLED</code>	Defines whether the result of a complex transform is ordered or permuted.
		Default value: <code>DFTI_ORDERED</code> .
<i>Read-Only configuration parameters</i>		
<code>DFTI_COMMIT_STATUS</code>	Named constant <code>DFTI_UNCOMMITTED</code> or <code>DFTI_COMMITTED</code>	Readiness of the descriptor for computation.
<code>DFTI_VERSION</code>	String	Version of Intel MKL. Assumed length of the string is <code>DFTI_VERSION_LENGTH</code> .

Configuring and Computing an FFT in C/C++

DFTI_PRECISION

The configuration parameter `DFTI_PRECISION` denotes the floating-point precision in which the transform is to be carried out. A setting of `DFTI_SINGLE` stands for single precision, and a setting of `DFTI_DOUBLE` stands for double precision. The data must be presented in this precision, the computation is carried out in this precision, and the result is delivered in this precision.

`DFTI_PRECISION` does not have a default value. Set it explicitly by calling the `DftiCreateDescriptor` function.

To better understand configuration of the precision of transforms, you can refer to these examples in your Intel MKL directory:

```
./examples/dftc/source/basic_sp_complex_dft_1d.c
```

```
./examples/dftc/source/basic_dp_complex_dft_1d.c
```

[DFTI_FORWARD_DOMAIN](#)

[DFTI_DIMENSION](#), [DFTI_LENGTHS](#)

[DftiCreateDescriptor](#)

DFTI_FORWARD_DOMAIN

The general form of a discrete Fourier transform is

$$z_{k_1, k_2, \dots, k_d} = \sigma \times \sum_{j_d=0}^{n_d-1} \dots \sum_{j_2=0}^{n_2-1} \sum_{j_1=0}^{n_1-1} w_{j_1 j_2 \dots j_d} \exp \left(\delta i 2\pi \sum_{l=1}^d j_l k_l / n_l \right)$$

for $k_l = 0, \dots, n_l-1$ ($l = 1, \dots, d$), where σ is a scale factor, $\delta = -1$ for the forward transform, and $\delta = +1$ for the backward transform.

The Intel MKL implementation of the FFT algorithm, used for fast computation of discrete Fourier transforms, supports forward transforms on input sequences of two domains, as specified by the `DFTI_FORWARD_DOMAIN` configuration parameter: general complex-valued sequences (`DFTI_COMPLEX` domain) and general real-valued sequences (`DFTI_REAL` domain). The forward transform maps the forward domain to the corresponding backward domain, as shown in [Table "Correspondence of Forward and Backward Domain"](#).

The conjugate-even domain covers complex-valued sequences with the symmetry property:

$$x(k_1, k_2, \dots, k_d) = \text{conjugate}(x(n_1 - k_1, n_2 - k_2, \dots, n_d - k_d))$$

where the index arithmetic is performed modulo respective size, that is,

$$x(\dots, \text{expr}_s, \dots) \equiv x(\dots, \text{mod}(\text{expr}_s, n_s), \dots),$$

and therefore

$$x(\dots, n_s, \dots) \equiv x(\dots, 0, \dots).$$

Due to this property of conjugate-even sequences, only a part of such sequence is stored in the computer memory, as described in [DFTI_CONJUGATE_EVEN_STORAGE](#).

Correspondence of Forward and Backward Domain

Forward Domain	Implied Backward Domain
Complex (<code>DFTI_COMPLEX</code>)	Complex (<code>DFTI_COMPLEX</code>)
Real (<code>DFTI_REAL</code>)	Conjugate-even

`DFTI_FORWARD_DOMAIN` does not have a default value. Set it explicitly by calling the `DftiCreateDescriptor` function.

To better understand usage of the `DFTI_FORWARD_DOMAIN` configuration parameter, you can refer to these examples in your Intel MKL directory:

```
./examples/dftc/source/basic_sp_complex_dft_1d.c
```

```
./examples/dftc/source/basic_sp_real_dft_1d.c
```

[DFTI_PRECISION](#)

[DFTI_DIMENSION](#), [DFTI_LENGTHS](#)

[DftiCreateDescriptor](#)

DFTI_DIMENSION, DFTI_LENGTHS

The dimension of the transform is a positive integer value represented in an integer scalar of `MKL_LONG` data type. For a one-dimensional transform, the transform length is specified by a positive integer value represented in an integer scalar of `MKL_LONG` data type. For multi-dimensional (≥ 2) transform, the lengths of each of the dimensions are supplied in an integer array (of `MKL_LONG` data type).

`DFTI_DIMENSION` and `DFTI_LENGTHS` do not have a default value. To set them, use the `DftiCreateDescriptor` function and not the `DftiSetValue` function.

To better understand usage of the `DFTI_DIMENSION` and `DFTI_LENGTHS` configuration parameters, you can refer to basic examples of one-, two-, and three-dimensional transforms in your Intel MKL directory. Naming conventions for the examples are self-explanatory. For example, refer to these examples of single-precision two-dimensional transforms:

```
./examples/dftc/source/basic_sp_real_dft_2d.c
```

```
./examples/dftc/source/basic_sp_complex_dft_2d.c
```

[DftiSetValue](#)

DFTI_FORWARD_SCALE, DFTI_BACKWARD_SCALE

The forward transform and backward transform are each associated with a scale factor σ of its own having the default value of 1. You can specify the scale factors using one or both of the configuration parameters `DFTI_FORWARD_SCALE` and `DFTI_BACKWARD_SCALE`. For example, for a one-dimensional transform of length n , you can use the default scale of 1 for the forward transform and set the scale factor for the backward transform to be $1/n$, thus making the backward transform the inverse of the forward transform.

Set the scale factor configuration parameter using a real floating-point data type of the same precision as the value for `DFTI_PRECISION`.

NOTE

For inquiry of the scale factor with the `DftiGetValue` function, the `config_val` parameter must have the same floating-point precision as the descriptor.

[DftiSetValue](#)

DFTI_THREAD_LIMIT

In some situations you may need to limit the number of threads that the `DftiComputeForward` and `DftiComputeBackward` functions use. For example, if more than one thread calls Intel MKL, it might be important that the thread calling these functions does not oversubscribe computing resources (CPU cores). Similarly, a known limit of the maximum number of threads to be used in computations might help the `DftiCommitDescriptor` function to select a more optimal computation method.

Set the parameter `DFTI_THREAD_LIMIT` as follows:

- To a positive number, to specify the maximum number of threads to be used by the compute functions.
- To zero (the default value), to use the maximum number of threads permitted in Intel MKL FFT functions. See "Techniques to Set the Number of Threads" in the *Intel MKL User's Guide* for more information.

On an attempt to set a negative value, the `DftiSetValue` function returns an error and does not update the descriptor.

The value of the `DFTI_THREAD_LIMIT` configuration parameter returned by the `DftiGetValue` function is defined as follows:

- 1 if Intel MKL runs in the sequential mode
- Depends on the commit status of the descriptor if Intel MKL runs in a threaded mode:

Commit Status	Value
Not committed	The value of <code>DFTI_THREAD_LIMIT</code> set in a previous call to the <code>DftiSetValue</code> function or the default value
Committed	The upper limit on the number of threads used by the <code>DftiComputeForward</code> and <code>DftiComputeBackward</code> functions

To better understand usage of the `DFTI_THREAD_LIMIT` configuration parameter, refer to the following example in your Intel MKL directory:

```
./examples/dftc/source/config_thread_limit.c
```

DFTI_COMMIT_STATUS

DFTI_INPUT_STRIDES, DFTI_OUTPUT_STRIDES

The FFT interface provides configuration parameters that define the layout of multidimensional data in the computer memory. For d -dimensional data set X defined by dimensions $N_1 \times N_2 \times \dots \times N_d$, the layout describes where a particular element $X(k_1, k_2, \dots, k_d)$ of the data set is located. The memory address of the element $X(k_1, k_2, \dots, k_d)$ is expressed by the formula

$$\begin{aligned} \text{address of } X(k_1, k_2, \dots, k_d) &= \text{address of } X(0, 0, \dots, 0) + \text{offset} \\ &= \text{address of } X(0, 0, \dots, 0) + s_0 + k_1*s_1 + k_2*s_2 + \dots + k_d*s_d, \end{aligned}$$

where s_0 is the displacement and $s_1, \dots, s_d$ are generalized strides. The configuration parameters `DFTI_INPUT_STRIDES` and `DFTI_OUTPUT_STRIDES` enable you to get and set these values. The configuration value is an array of values $(s_0, s_1, \dots, s_d)$ of `MKL_LONG` data type.

The offset is counted in elements of the data type defined by the descriptor configuration (rather than by the type of the variable passed to the computation functions). Specifically, the `DFTI_FORWARD_DOMAIN`, `DFTI_COMPLEX_STORAGE`, and `DFTI_CONJUGATE_EVEN_STORAGE` configuration parameters define the type of the elements as shown in [Table "Assumed Element Types of the Input/Output Data"](#):

Assumed Element Types of the Input/Output Data

Descriptor Configuration	Element Type in the Forward Domain	Element Type in the Backward Domain
<code>DFTI_FORWARD_DOMAIN=DFTI_COMPLEX</code> <code>DFTI_COMPLEX_STORAGE=DFTI_COMPLEX_COMPLEX</code>	Complex	Complex
<code>DFTI_FORWARD_DOMAIN=DFTI_COMPLEX</code> <code>DFTI_COMPLEX_STORAGE=DFTI_REAL_REAL</code>	Real	Real
<code>DFTI_FORWARD_DOMAIN=DFTI_REAL</code> <code>DFTI_CONJUGATE_EVEN_STORAGE=DFTI_COMPLEX_REAL</code>	Real	Real
<code>DFTI_FORWARD_DOMAIN=DFTI_REAL</code> <code>DFTI_CONJUGATE_EVEN_STORAGE=DFTI_COMPLEX_COMPLEX</code>	Real	Complex

The `DFTI_INPUT_STRIDES` configuration parameter defines the layout of the input data, while the element type is defined by the forward domain for the `DftiComputeForward` function and by the backward domain for the `DftiComputeBackward` function. The `DFTI_OUTPUT_STRIDES` configuration parameter defines the layout of the output data, while the element type is defined by the backward domain for the `DftiComputeForward` function and by the forward domain for `DftiComputeBackward` function.

NOTE

The `DFTI_INPUT_STRIDES` and `DFTI_OUTPUT_STRIDES` configuration parameters define the layout of input and output data, and not the forward-domain and backward-domain data. If the data layouts in forward domain and backward domain differ, set `DFTI_INPUT_STRIDES` and `DFTI_OUTPUT_STRIDES` explicitly and then commit the descriptor before calling computation functions.

For in-place transforms (`DFTI_PLACEMENT=DFTI_INPLACE`), the configuration set by `DFTI_OUTPUT_STRIDES` is ignored when the element types in the forward and backward domains are the same. If they are different, set `DFTI_OUTPUT_STRIDES` explicitly (even though the transform is in-place). Ensure a consistent configuration for in-place transforms, that is, the locations of the first elements on input and output must coincide in each dimension.

The FFT interface supports both positive and negative stride values. If you use negative strides, set the displacement of the data as follows:

$$s_0 = \sum_{i=1}^d (N_i - 1) \cdot \max(-s_i, 0).$$

The default setting of strides in a general multi-dimensional case assumes that the array that contains the data has no padding. The order of the strides depends on the programming language. For example:

```
MKL_LONG dims[] = { nd, ..., n2, n1 };
DftiCreateDescriptor( &hand, precision, domain, d, dims );
// The above call assumes data declaration: type X[nd]...[n2][n1]
// Default strides are { 0, nd*...*n2*n1, ..., n2*n1, n1, 1 }
```

Note that in case of a real FFT (`DFTI_FORWARD_DOMAIN=DFTI_REAL`), where different data layouts in the backward domain are available (see [DFTI_PACKED_FORMAT](#)), the default value of the strides is not intuitive for the recommended CCE format (configuration setting `DFTI_CONJUGATE_EVEN_STORAGE=DFTI_COMPLEX_COMPLEX`). In case of an *in-place* real transform with the CCE format, set the strides explicitly, as follows:

```
MKL_LONG dims[] = { nd, ..., n2, n1 };
MKL_LONG rstrides[] = { 0, 2*nd*...*n2*(n1/2+1), ..., 2*n2*(n1/2+1), 2*(n1/2+1), 1 };
MKL_LONG cstrides[] = { 0, nd*...*n2*(n1/2+1), ..., n2*(n1/2+1), (n1/2+1), 1 };
DftiCreateDescriptor( &hand, precision, DFTI_REAL, d, dims );
DftiSetValue(hand, DFTI_CONJUGATE_EVEN_STORAGE, DFTI_COMPLEX_COMPLEX);
// Set the strides appropriately for forward/backward transform
```

To better understand configuration of strides, you can also refer to these examples in your Intel MKL directory:

```
./examples/dftc/source/basic_sp_real_dft_2d.c
./examples/dftc/source/basic_sp_real_dft_3d.c
./examples/dftc/source/basic_dp_real_dft_2d.c
./examples/dftc/source/basic_dp_real_dft_3d.c
```

DFTI_NUMBER_OF_TRANSFORMS

If you need to perform a large number of identical FFTs, you can do this in a single call to a `DftiCompute*` function with the value of the `DFTI_NUMBER_OF_TRANSFORMS` configuration parameter equal to the actual number of the transforms. The default value of this parameter is one. You can set this parameter to a positive integer value using the `MKL_LONG` data type. When setting the number of transforms to a value greater than one, you also need to specify the distance between the input and output data sets using one of the `DFTI_INPUT_DISTANCE` and `DFTI_OUTPUT_DISTANCE` configuration parameters or both.

-
- The data sets to be transformed must not have common elements.
 - All the sets of data must be located within the same memory block.
-

To better understand usage of the `DFTI_NUMBER_OF_TRANSFORMS` configuration parameter, refer to the following example in your Intel MKL directory:

```
./examples/dftc/source/config_number_of_transforms.c
```

[FFT Computation Functions](#)

[DFTI_INPUT_DISTANCE](#), [DFTI_OUTPUT_DISTANCE](#)
[DftiSetValue](#)

[DFTI_INPUT_DISTANCE](#), [DFTI_OUTPUT_DISTANCE](#)

The FFT interface in Intel MKL enables computation of multiple transforms. To compute multiple transforms, you need to specify the data distribution of the multiple sets of data. The distance between the first data elements of consecutive data sets, [DFTI_INPUT_DISTANCE](#) for input data or [DFTI_OUTPUT_DISTANCE](#) for output data, specifies the distribution. The configuration setting is a value of [MKL_LONG](#) data type.

The default value for both configuration settings is one. You must set this parameter explicitly if the number of transforms is greater than one (see [DFTI_NUMBER_OF_TRANSFORMS](#)).

The distance is counted in elements of the data type defined by the descriptor configuration (rather than by the type of the variable passed to the computation functions). Specifically, the [DFTI_FORWARD_DOMAIN](#), [DFTI_COMPLEX_STORAGE](#), and [DFTI_CONJUGATE_EVEN_STORAGE](#) configuration parameters define the type of the elements as shown in [Table "Assumed Element Types of the Input/Output Data"](#).

NOTE

The configuration parameters [DFTI_INPUT_DISTANCE](#) and [DFTI_OUTPUT_DISTANCE](#) define the distance within input and output data, and not within the forward-domain and backward-domain data. If the distances in the forward and backward domains differ, set [DFTI_INPUT_DISTANCE](#) and [DFTI_OUTPUT_DISTANCE](#) explicitly and then commit the descriptor before calling computation functions.

For in-place transforms ([DFTI_PLACEMENT=DFTI_INPLACE](#)), the configuration set by [DFTI_OUTPUT_DISTANCE](#) is ignored when the element types in the forward and backward domains are the same. If they are different, set [DFTI_OUTPUT_DISTANCE](#) explicitly (even though the transform is in-place). Ensure a consistent configuration for in-place transforms, that is, the locations of the data sets on input and output must coincide.

The following example illustrates setting of the [DFTI_INPUT_DISTANCE](#) configuration parameter:

```
MKL_LONG dims[] = { nd, ..., n2, n1 };
MKL_LONG distance = nd*...*n2*n1;
DftiCreateDescriptor( &hand, precision, DFTI_COMPLEX, d, dims );
DftiSetValue( hand, DFTI_NUMBER_OF_TRANSFORMS, (MKL_LONG)howmany );
DftiSetValue( hand, DFTI_INPUT_DISTANCE, distance );
```

To better understand configuration of the distances, you can also refer to the following example in your Intel MKL directory:

```
./examples/dftc/source/config_number_of_transforms.c
```

[DftiComputeForward](#)
[DftiComputeBackward](#)

[DFTI_COMPLEX_STORAGE](#), [DFTI_REAL_STORAGE](#), [DFTI_CONJUGATE_EVEN_STORAGE](#)

Depending on the value of the [DFTI_FORWARD_DOMAIN](#) configuration parameter, the implementation of FFT supports several storage schemes for input and output data (see document [3] for the rationale behind the definition of the storage schemes). The data elements are placed within contiguous memory blocks, defined with generalized strides (see [DFTI_INPUT_STRIDES](#), [DFTI_OUTPUT_STRIDES](#)). For multiple transforms, all sets of data should be located within the same memory block, and the data sets should be placed at the same distance from each other (see [DFTI_NUMBER_OF_TRANSFORMS](#) and [DFTI_INPUT_DISTANCE](#), [DFTI_OUTPUT_DISTANCE](#)).

TIP

Avoid setting up multidimensional arrays with lists of pointers to one-dimensional arrays. Instead use a one-dimensional array with the explicit indexing to access the data elements.

FFT Examples demonstrate the usage of storage formats.

DFTI_COMPLEX_STORAGE: storage schemes for a complex domain

For the `DFTI_COMPLEX` forward domain, both input and output sequences belong to a complex domain. In this case, the configuration parameter `DFTI_COMPLEX_STORAGE` can have one of the two values:

`DFTI_COMPLEX_COMPLEX` (default) or `DFTI_REAL_REAL`.

NOTE

In the Intel MKL FFT interface, storage schemes for a forward complex domain and the respective backward complex domain are the same.

With `DFTI_COMPLEX_COMPLEX` storage, complex-valued data sequences are referenced by a single complex parameter (array) `AZ` so that a complex-valued element $z_{k_1, k_2, \dots, k_d}$ of the m -th d -dimensional sequence is located at `AZ[m*distance + stride0 + k1*stride1 + k2*stride2+ ... kd*strided]` as a structure consisting of the real and imaginary parts.

The following code illustrates usage of the `DFTI_COMPLEX_COMPLEX` storage:

```
complex *AZ = malloc( N1*N2*N3*M * sizeof(AZ[0]) );
MKL_LONG ios[4], iodist; // input/output strides and distance
...
// on input: Z{k1,k2,k3,m}
// = AZ[ ios[0] + k1*ios[1] + k2*ios[2] + k3*ios[3] + m*iodist ]
status = DftiComputeForward( desc, AZ );
// on output: Z{k1,k2,k3,m}
// = AZ[ ios[0] + k1*ios[1] + k2*ios[2] + k3*ios[3] + m*iodist ]
```

With the `DFTI_REAL_REAL` storage, complex-valued data sequences are referenced by two real parameters `AR` and `AI` so that a complex-valued element $z_{k_1, k_2, \dots, k_d}$ of the m -th sequence is computed as $AR[m*distance + stride0 + k_1*stride_1 + k_2*stride_2 + \dots + k_d*stride_d] + \sqrt{-1} * AI[m*distance + stride0 + k_1*stride_1 + k_2*stride_2 + \dots + k_d*stride_d]$.

The following code illustrates usage of the `DFTI_REAL_REAL` storage:

```
float *AR = malloc( N1*N2*N3*M * sizeof(AR[0]) );
float *AI = malloc( N1*N2*N3*M * sizeof(AI[0]) );
MKL_LONG ios[4], iodist; // input/output strides and distance
...
// on input: Z{k1,...,kd,m}
// = AR[ ios[0] + k1*ios[1] + k2*ios[2] + k3*ios[3] + m*iodist ]
// + I*AI[ ios[0] + k1*ios[1] + k2*ios[2] + k3*ios[3] + m*iodist ]
status = DftiComputeForward( desc, AR, AI );
// on output: Z{k1,...,kd,m}
// = AR[ ios[0] + k1*ios[1] + k2*ios[2] + k3*ios[3] + m*iodist ]
// + I*AI[ ios[0] + k1*ios[1] + k2*ios[2] + k3*ios[3] + m*iodist ]
```

DFTI_REAL_STORAGE: storage schemes for a real domain

The Intel MKL FFT interface supports only one configuration value for this storage scheme: `DFTI_REAL_REAL`.

With the `DFTI_REAL_REAL` storage, real-valued data sequences in a real domain are referenced by one real parameter `AR` so that real-valued element of the m -th sequence is located as `AR[m*distance + stride0 + k1*stride1 + k2*stride2+ ... kd*strided]`.

DFTI_CONJUGATE_EVEN_STORAGE: storage scheme for a conjugate-even domain

The Intel MKL FFT interface supports two configuration values for this parameter: `DFTI_COMPLEX_REAL` (default) and `DFTI_COMPLEX_COMPLEX`. In both cases, the conjugate-even symmetry of the data enables storing only about a half of the whole mathematical result, so that one part of it can be directly referenced in the memory while the other part can be reconstructed depending on the selected storage configuration.

With the `DFTI_COMPLEX_REAL` storage, the complex-valued data sequences in the conjugate-even domain can be reconstructed as described in section [DFTI_PACKED_FORMAT](#).

Important

Although `DFTI_CONJUGATE_EVEN_STORAGE=DFTI_COMPLEX_REAL` is the default setting for the `DFTI_REAL` forward domain, avoid using this storage scheme because it is supported only for one- and two-dimensional transforms and will be deprecated in future.

With the `DFTI_COMPLEX_COMPLEX` storage, the complex-valued data sequences in the conjugate-even domain are referenced by one complex parameter `AZ` so that a complex-valued element $z_{k_1, k_2, \dots, k_d}$ of the m -th sequence can be referenced or reconstructed as described below.

Important

Use the `DFTI_CONJUGATE_EVEN_STORAGE=DFTI_COMPLEX_COMPLEX` configuration setting, which will become the default in future. This setting is supported for all transform ranks, provides a uniform pattern for reconstructing the entire conjugate-even sequence from the part of it that is actually stored, and is compatible with data layouts supported by other FFT libraries, such as FFTW. This storage scheme disregards the setting of `DFTI_PACKED_FORMAT`.

Consider a d -dimensional real-to-complex transform

$$Z_{k_1, k_2, \dots, k_d} \equiv \sum_{n_1=0}^{N_1-1} \dots \sum_{n_d=0}^{N_d-1} R_{n_1, n_2, \dots, n_d} e^{\frac{-2\pi i}{N_1} k_1 n_1} \dots e^{\frac{-2\pi i}{N_d} k_d n_d}$$

Because the input sequence R is real-valued, the mathematical result Z has conjugate-even symmetry:

$$z_{k_1, k_2, \dots, k_d} = \text{conjugate}(z_{N_1-k_1, N_2-k_2, \dots, N_d-k_d}),$$

where index arithmetic is performed modulo the length of the respective dimension. Obviously, the first element of the result is real-valued:

$$z_{0, 0, \dots, 0} = \text{conjugate}(z_{0, 0, \dots, 0}).$$

For dimensions with even lengths, the other elements are real-valued too. For example, if N_s is even,

$$z_{0, 0, \dots, N_s/2, 0, \dots, 0} = \text{conjugate}(z_{0, 0, \dots, N_s/2, 0, \dots, 0}).$$

With the conjugate-even symmetry, approximately a half of the result suffices to fully reconstruct it. For an arbitrary dimension h , it suffices to store elements $z_{k_1, \dots, k_h, \dots, k_d}$ for the following indices:

- $k_h = 0, \dots, [N_h/2]$
- $k_i = 0, \dots, N_i - 1$, where $i = 1, \dots, d$ and $i \neq h$

The symmetry property enables reconstructing the remaining elements: for $k_h = [N_h/2] + 1, \dots, N_h - 1$. In the Intel MKL FFT interface, the halved dimension is the last dimension.

The following code illustrates usage of the `DFTI_COMPLEX_COMPLEX` storage for a conjugate-even domain:

```
float *AR = malloc( N1*N2*M * sizeof(AR[0]) );
complex *AZ = malloc( N1*(N2/2+1)*M * sizeof(AZ[0]) );
MKL_LONG is[3], os[3], idist, odist; // input and output strides and distance
...
// on input: R{k1,k2,m}
// = AR[is[0] + k1*is[1] + k2*is[2] + m*idist]
status = DftiComputeForward( desc, R, C );
// on output:
// for k2=0...N2/2:      Z{k1,k2,m} = AZ[os[0]+k1*os[1]+k2*os[2]+m*odist]
// for k2=N2/2+1...N2-1: Z{k1,k2,m} = conj(AZ[os[0]+(N1-k1)%N1*os[1]
//                                     + (N2-k2)%N2*os[2]+m*odist])
```

For the backward transform, the input and output parameters and layouts exchange roles: set the strides describing the layout in the backward/forward domain as input/output strides, respectively. For example:

```
...
status = DftiSetValue( desc, DFTI_INPUT_STRIDES, fwd_domain_strides );
status = DftiSetValue( desc, DFTI_OUTPUT_STRIDES, bwd_domain_strides );
status = DftiCommitDescriptor( desc );
status = DftiComputeForward( desc, ... );
...
status = DftiSetValue( desc, DFTI_INPUT_STRIDES, bwd_domain_strides );
status = DftiSetValue( desc, DFTI_OUTPUT_STRIDES, fwd_domain_strides );
status = DftiCommitDescriptor( desc );
status = DftiComputeBackward( desc, ... );
```

Important

For in-place transforms, ensure the first element of the input data has the same address as the first element of the output data for each dimension.

DFTI_PACKED_FORMAT

The result of the forward transform of real data is a conjugate-even sequence. Due to the symmetry property, only a part of the complex-valued sequence is stored in memory. The `DFTI_PACKED_FORMAT` configuration parameter defines how the data is packed. Possible values of `DFTI_PACKED_FORMAT` depend on the values of the [DFTI_CONJUGATE_EVEN_STORAGE](#) configuration parameter:

- `DFTI_CONJUGATE_EVEN_STORAGE=DFTI_COMPLEX_COMPLEX`.

The only value of `DFTI_PACKED_FORMAT` can be `DFTI_CCE_FORMAT`. You can use this value with transforms of any dimension. For a description of the corresponding packed format, see [DFTI_CONJUGATE_EVEN_STORAGE](#).

- `DFTI_CONJUGATE_EVEN_STORAGE=DFTI_COMPLEX_REAL`.

`DFTI_PACKED_FORMAT` can be [DFTI_CCS_FORMAT](#), [DFTI_PACK_FORMAT](#), or [DFTI_PERM_FORMAT](#). You can use these values with one- and two-dimensional transforms only. The corresponding packed formats are described below.

NOTE

Although `DFTI_CONJUGATE_EVEN_STORAGE=DFTI_COMPLEX_REAL` is the default setting for the `DFTI_REAL` forward domain, avoid using this storage scheme because it is supported only for one- and two-dimensional transforms, is incompatible with storage schemes of other FFT libraries, and will be deprecated in future.

DFTI_CCS_FORMAT for One-dimensional Transforms

The following figure illustrates the storage of a one-dimensional (1D) size- N conjugate-even sequence in a real array for the CCS, PACK, and PERM packed formats. The CCS format requires an array of size $N+2$, while the other formats require an array of size N . Zero-based indexing is used.

Storage of a 1D Size- N Conjugate-even Sequence in a Real Array

	n=	0	1	2	3	...	2L-2	2L-1	2L	2L+1	2L+2
CCS, N=2L		R_0	0	R_1	I_1	...	R_{L-1}	I_{L-1}	R_L	0	
PACK, N=2L		R_0	R_1	I_1	R_2	...	I_{L-1}	R_L			
PERM, N=2L		R_0	R_L	R_1	I_1	...	R_{L-1}	I_{L-1}			
CCS, N=2L+1		R_0	0	R_1	I_1	...	R_{L-1}	I_{L-1}	R_L	I_L	not used
PACK, N=2L+1		R_0	R_1	I_1	R_2	...	I_{L-1}	R_L	I_L		
PERM, N=2L+1		R_0	R_1	I_1	R_2	...	I_{L-1}	R_L	I_L		

The real and imaginary parts of the complex-valued conjugate-even sequence Z_k are located in a real-valued array AC as illustrated by figure "Storage of a 1D Size- N Conjugate-even Sequence in a Real Array" and can be used to reconstruct the whole conjugate-even sequence as follows:

```
float *AR; // malloc( sizeof(float)*N )
float *AC; // malloc( sizeof(float)*(N+2) )
...
status = DftiSetValue( desc, DFTI_PACKED_FORMAT, DFTI_CCS_FORMAT );
...
// on input: R{k} = AR[k]
status = DftiComputeForward( desc, AR, AC ); // real-to-complex FFT
// on output:
// for k=0...N/2:    Z{k} = AC[2*k+0] + I*AC[2*k+1]
// for k=N/2+1...N-1: Z{k} = AC[2*(N-k)%N + 0] - I*AC[2*(N-k)%N + 1]
```

DFTI_CCS_FORMAT for Two-dimensional Transforms

The following figure illustrates the storage of a two-dimensional (2D) M -by- N conjugate-even sequence in a real array for the CCS packed format. This format requires an array of size $(M+2)$ -by- $(N+2)$. Row-major layout and zero-based indexing are used. Different colors mark logically separate parts of the result. "n/u" means "not used".

The real and imaginary parts of the complex-valued conjugate-even sequence $Z_{k1,k2}$ are located in real-valued array AC as illustrated by figure "Storage of a 2D M -by- N Conjugate-even Sequence in a Real Array for the PERM Format" and can be used to reconstruct the whole sequence as follows:

```
float *AR; // malloc( sizeof(float)*N1*N2 )
float *AC; // malloc( sizeof(float)*N1*N2 )
...
status = DftiSetValue( desc, DFTI_PACKED_FORMAT, DFTI_PERM_FORMAT );
...
// on input: R{k1,k2} = AR[N2*k1 + k2]
status = DftiComputeForward( desc, AR, AC ); // real-to-complex FFT
// on output: Z{k1,k2} = re + I*im, where
// if (k1==0) {
//     if (k2 == 0) {
//         re = AC[0];
```

```
//      im = 0;
//      } else if (k2 == N2-k2) {
//          re = AC[1];
//          im = 0;
//      } else if (k2 <= N2/2) {
//          re = AC[2*k2+0 - N2%2];
//          im = AC[2*k2+1 - N2%2];
//      } else {
//          re = AC[2*(N2-k2)+0 - N2%2];
//          im = -AC[2*(N2-k2)+1 - N2%2];
//      }
//  } else if (k2==0) {
//      if (k1 == N1-k1) {
//          re = AC[N2];
//          im = 0;
//      } else if (k1 <= N1/2) {
//          re = AC[(2*k1+0 - N1%2)*N2];
//          im = AC[(2*k1+1 - N1%2)*N2];
//      } else {
//          re = AC[(2*(N1-k1)+0 - N1%2)*N2];
//          im = -AC[(2*(N1-k1)+1 - N1%2)*N2];
//      }
//  } else if (k2 == N2-k2) {
//      if (k1 == N1-k1) {
//          re = AC[N2 + 1];
//          im = 0;
//      } else if (k1 <= N1/2) {
//          re = AC[(2*k1+0 - N1%2)*N2 + 1];
//          im = AC[(2*k1+1 - N1%2)*N2 + 1];
//      } else {
//          re = AC[(2*(N1-k1)+0 - N1%2)*N2 + 1];
//          im = -AC[(2*(N1-k1)+1 - N1%2)*N2 + 1];
//      }
//  } else if (k2 <= N2/2) {
//      re = AC[k1*N2+2*k2+0 - N2%2];
//      im = AC[k1*N2+2*k2+1 - N2%2];
//  } else {
//      re = AC[(N1-k1)*N2+2*(N2-k2)+0 - N2%2];
//      im = -AC[(N1-k1)*N2+2*(N2-k2)+1 - N2%2];
//  }
// }
```

To better understand packed formats for two-dimensional transforms, refer to the following example in your Intel MKL directory:

`./examples/dftc/source/config_conjugate_even_storage.c`

DFTI_WORKSPACE

The computation step for some FFT algorithms requires a scratch space for permutation or other purposes. To manage the use of the auxiliary storage, Intel MKL enables you to set the configuration parameter `DFTI_WORKSPACE` with the following values:

<code>DFTI_ALLOW</code>	(default) Permits the use of the auxiliary storage.
<code>DFTI_AVOID</code>	Instructs Intel MKL to avoid using the auxiliary storage if possible.

[DftiSetValue](#)

DFTI_COMMIT_STATUS

The `DFTI_COMMIT_STATUS` configuration parameter indicates whether the descriptor is ready for computation. The parameter has two possible values:

`DFTI_UNCOMMITTED` Default value, set after a successful call of `DftiCreateDescriptor`.

`DFTI_COMMITTED` The value after a successful call to `DftiCommitDescriptor`.

A computation function called with an uncommitted descriptor returns an error.

You cannot directly set this configuration parameter in a call to `DftiSetValue`, but a change in the configuration of a committed descriptor may change the commit status of the descriptor to

`DFTI_UNCOMMITTED`.

DFTI_ORDERING

Some FFT algorithms apply an explicit permutation stage that is time consuming [4]. The exclusion of this step is similar to applying an FFT to input data whose order is scrambled, or allowing a scrambled order of the FFT results. In applications such as convolution and power spectrum calculation, the order of result or data is unimportant and thus using scrambled data is acceptable if it leads to better performance. The following options are available in Intel MKL:

- `DFTI_ORDERED`: Forward transform data ordered, backward transform data ordered (default option).
- `DFTI_BACKWARD_SCRAMBLED`: Forward transform data ordered, backward transform data scrambled.

Table "Scrambled Order Transform" tabulates the effect of this configuration setting.

Scrambled Order Transform

	<code>DftiComputeForward</code>	<code>DftiComputeBackward</code>
DFTI_ORDERING	Input → Output	Input → Output
<code>DFTI_ORDERED</code>	ordered → ordered	ordered → ordered
<code>DFTI_BACKWARD_SCRAMBLED</code>	ordered → scrambled	scrambled → ordered

NOTE

The word "scrambled" in this table means "permit scrambled order if possible". In some situations permitting out-of-order data gives no performance advantage and an implementation may choose to ignore the suggestion.

Descriptor Manipulation Functions

This category contains the following functions: create a descriptor, commit a descriptor, copy a descriptor, and free a descriptor.

DftiCreateDescriptor

Allocates the descriptor data structure and initializes it with default configuration values.

Syntax

```
status = DftiCreateDescriptor(&desc_handle, precision, forward_domain, dimension,
length);
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>precision</i>	enum	Precision of the transform: DFTI_SINGLE or DFTI_DOUBLE.
<i>forward_domain</i>	enum	Forward domain of the transform: DFTI_COMPLEX or DFTI_REAL.
<i>dimension</i>	MKL_LONG	Dimension of the transform.
<i>length</i>	MKL_LONG if <i>dimension</i> = 1. Array of type MKL_LONG otherwise.	Length of the transform for a one-dimensional transform. Lengths of each dimension for a multi-dimensional transform.

Output Parameters

Name	Type	Description
<i>desc_handle</i>	DFTI_DESCRIPTOR_HANDLE	FFT descriptor.
<i>status</i>	MKL_LONG	Function completion status.

Description

This function allocates memory for the descriptor data structure and instantiates it with all the default configuration settings for the precision, forward domain, dimension, and length of the desired transform. Because memory is allocated dynamically, the result is actually a pointer to the created descriptor. This function is slightly different from the "initialization" function that can be found in software packages or libraries that implement more traditional algorithms for computing an FFT. This function does not perform any significant computational work such as computation of twiddle factors. The function [DftiCommitDescriptor](#) does this work after the function [DftiSetValue](#) has set values of all necessary parameters.

The function returns zero when it completes successfully. See [Status Checking Functions](#) for more information on the returned status.

Prototype

```
/* Note that the preprocessor definition provided below only illustrates
 * that the actual function called may be determined at compile time.
 * You can rely only on the declaration of the function.
 * For precise definition of the preprocessor macro, see the include/mkl_dfti.h
 * file in the Intel MKL directory.
 */
MKL_LONG DftiCreateDescriptor(DFTI_DESCRIPTOR_HANDLE * pHandle,
```

```
enum DFTI_CONFIG_VALUE precision,
enum DFTI_CONFIG_VALUE domain,
MKL_LONG dimension, ... /* length/lengths */ );

#define DftiCreateDescriptor(desc,prec,domain,dim,sizes) \
    ((prec)==DFTI_SINGLE && (dim)==1) ? \
    some_actual_function_sld((desc),(domain),(MKL_LONG)(sizes)) : \
    ...
```

Variable *length/lengths* is interpreted as a scalar (MKL_LONG) or an array (MKL_LONG*), depending on the value of parameter *dimension*. If the value of parameter *precision* is known at compile time, an optimizing compiler retains only the call to the respective specific function, thereby reducing the size of the statically linked application. Avoid direct calls to the specific functions used in the preprocessor macro definition, because their interface may change in future releases of the library. If the use of the macro is undesirable, you can safely undefine it after inclusion of the Intel MKL FFT header file, as follows:

```
#include "mkl_dfti.h"
#undef DftiCreateDescriptor
```

See Also

[DFTI_DIMENSION](#), [DFTI_LENGTHS](#) configuration parameters

[Configuration Parameters](#)

DftiCommitDescriptor

Performs all initialization for the actual FFT computation.

Syntax

```
status = DftiCommitDescriptor(desc_handle);
```

Include Files

- `mkl.h`

Input Parameters

Name	Type	Description
<i>desc_handle</i>	DFTI_DESCRIPTOR_HANDLE	FFT descriptor.

Output Parameters

Name	Type	Description
<i>desc_handle</i>	DFTI_DESCRIPTOR_HANDLE	Updated FFT descriptor.
<i>status</i>	MKL_LONG	Function completion status.

Description

This function completes initialization of a previously created descriptor, which is required before the descriptor can be used for FFT computations. Typically, committing the descriptor performs all initialization that is required for the actual FFT computation. The initialization done by the function may involve exploring different factorizations of the input length to find the optimal computation method.

If you call the `DftiSetValue` function to change configuration parameters of a committed descriptor (see [Descriptor Configuration Functions](#)), you must re-commit the descriptor before invoking a computation function. Typically, a commit function call is immediately followed by a computation function call (see [FFT Computation Functions](#)).

The function returns zero when it completes successfully. See [Status Checking Functions](#) for more information on the returned status.

Prototype

```
MKL_LONG DftiCommitDescriptor( DFTI_DESCRIPTOR_HANDLE );
```

DftiFreeDescriptor

Frees the memory allocated for a descriptor.

Syntax

```
status = DftiFreeDescriptor(&desc_handle);
```

Include Files

- `mkl.h`

Input Parameters

Name	Type	Description
<i>desc_handle</i>	DFTI_DESCRIPTOR_HANDLE	FFT descriptor.

Output Parameters

Name	Type	Description
<i>desc_handle</i>	DFTI_DESCRIPTOR_HANDLE	Memory for the FFT descriptor is released.
<i>status</i>	MKL_LONG	Function completion status.

Description

This function frees all memory allocated for a descriptor.

NOTE

Memory allocation/deallocation inside Intel MKL is managed by Intel MKL memory management software. So, even after successful completion of `FreeDescriptor`, the memory space may continue being allocated for the application because the memory management software sometimes does not return the memory space to the OS, but considers the space free and can reuse it for future memory allocation. See [Example "mkl_free_buffers Usage with FFT Functions"](#) in the description of the service function `FreeBuffers` on how to use Intel MKL memory management software and release memory to the OS.

The function returns zero when it completes successfully. See [Status Checking Functions](#) for more information on the returned status.

Prototype

```
MKL_LONG DftiFreeDescriptor( DFTI_DESCRIPTOR_HANDLE * );
```

DftiCopyDescriptor

Makes a copy of an existing descriptor.

Syntax

```
status = DftiCopyDescriptor(desc_handle_original, &desc_handle_copy);
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>desc_handle_original</i>	DFTI_DESCRIPTOR_HANDLE	The FFT descriptor to copy.

Output Parameters

Name	Type	Description
<i>desc_handle_copy</i>	DFTI_DESCRIPTOR_HANDLE	The copy of the FFT descriptor.
<i>status</i>	MKL_LONG	Function completion status.

Description

This function makes a copy of an existing descriptor. The resulting descriptor *desc_handle_copy* and the existing descriptor *desc_handle_original* specify the same configuration of the transform, but do not have any memory areas in common ("deep copy").

The function returns zero when it completes successfully. See [Status Checking Functions](#) for more information on the returned status.

Prototype

```
MKL_LONG DftiCopyDescriptor( DFTI_DESCRIPTOR_HANDLE, DFTI_DESCRIPTOR_HANDLE * );
```

Descriptor Configuration Functions

This category contains the following functions: the value setting function [DftiSetValue](#) sets one particular configuration parameter to an appropriate value, and the value getting function [DftiGetValue](#) reads the value of one particular configuration parameter. While all configuration parameters are readable, you cannot set a few of them. Some of these contain fixed information of a particular implementation such as version number, or dynamic information, which is derived by the implementation during execution of one of the functions. See [Configuration Settings](#) for details.

DftiSetValue

Sets one particular configuration parameter with the specified configuration value.

Syntax

```
status = DftiSetValue(desc_handle, config_param, config_val);
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<code>desc_handle</code>	<code>DFTI_DESCRIPTOR_HANDLE</code>	FFT descriptor.
<code>config_param</code>	enum	Configuration parameter.
<code>config_val</code>	Depends on the configuration parameter.	Configuration value.

Output Parameters

Name	Type	Description
<code>desc_handle</code>	<code>DFTI_DESCRIPTOR_HANDLE</code>	Updated FFT descriptor.
<code>status</code>	<code>MKL_LONG</code>	Function completion status.

Description

This function sets one particular configuration parameter with the specified configuration value. Each configuration parameter is a named constant, and the configuration value must have the corresponding type, which can be a named constant or a native type. For available configuration parameters and the corresponding configuration values, see:

- `DFTI_PRECISION`
- `DFTI_FORWARD_DOMAIN`
- `DFTI_DIMENSION`, `DFTI_LENGTH`
- `DFTI_PLACEMENT`
- `DFTI_FORWARD_SCALE`, `DFTI_BACKWARD_SCALE`
- `DFTI_THREAD_LIMIT`
- `DFTI_INPUT_STRIDES`, `DFTI_OUTPUT_STRIDES`
- `DFTI_NUMBER_OF_TRANSFORMS`
- `DFTI_INPUT_DISTANCE`, `DFTI_OUTPUT_DISTANCE`
- `DFTI_COMPLEX_STORAGE`, `DFTI_REAL_STORAGE`, `DFTI_CONJUGATE_EVEN_STORAGE`
- `DFTI_PACKED_FORMAT`
- `DFTI_WORKSPACE`
- `DFTI_ORDERING`

The `DftiSetValue` function cannot be used to change configuration parameters `DFTI_FORWARD_DOMAIN`, `DFTI_PRECISION`, `DFTI_DIMENSION`, and `DFTI_LENGTHS`. Use the `DftiCreateDescriptor` function to set them.

Function calls needed to configure an FFT descriptor for a particular call to an FFT computation function are summarized in [Configuring and Computing an FFT in C C++](#).

The function returns zero when it completes successfully. See [Status Checking Functions](#) for more information on the returned status.

Prototype

```
MKL_LONG DftiSetValue( DFTI_DESCRIPTOR_HANDLE, DFTI_CONFIG_PARAM , ... );
```

See Also

[Configuration Settings](#) for more information on configuration parameters.

[DftiCreateDescriptor](#)

[DftiGetValue](#)

DftiGetValue

Gets the configuration value of one particular configuration parameter.

Syntax

```
status = DftiGetValue(desc_handle, config_param, &config_val);
```

Include Files

- `mkl.h`

Input Parameters

Name	Type	Description
<code>desc_handle</code>	<code>DFTI_DESCRIPTOR_HANDLE</code>	FFT descriptor.
<code>config_param</code>	enum	Configuration parameter. See Table "Configuration Parameters" for allowable values of <code>config_param</code> .

Output Parameters

Name	Type	Description
<code>config_val</code>	Depends on the configuration parameter.	Configuration value.
<code>status</code>	<code>MKL_LONG</code>	Function completion status.

Description

This function gets the configuration value of one particular configuration parameter. Each configuration parameter is a named constant, and the configuration value must have the corresponding type, which can be a named constant or a native type. For available configuration parameters and the corresponding configuration values, see:

- `DFTI_PRECISION`
- `DFTI_FORWARD_DOMAIN`
- `DFTI_DIMENSION`, `DFTI_LENGTH`
- `DFTI_PLACEMENT`
- `DFTI_FORWARD_SCALE`, `DFTI_BACKWARD_SCALE`
- `DFTI_THREAD_LIMIT`
- `DFTI_INPUT_STRIDES`, `DFTI_OUTPUT_STRIDES`

- [DFTI_PACKED_FORMAT](#)
- [DFTI_WORKSPACE](#)
- [DFTI_COMMIT_STATUS](#)
- [DFTI_ORDERING](#)

The function returns zero when it completes successfully. See [Status Checking Functions](#) for more information on the returned status.

Prototype

```
MKL_LONG DftiGetValue( DFTI_DESCRIPTOR_HANDLE,
    DFTI_CONFIG_PARAM ,
    ... );
```

See Also

[Configuration Settings](#) for more information on configuration parameters.

[DftiSetValue](#)

FFT Computation Functions

This category contains the following functions: compute the forward transform and compute the backward transform.

DftiComputeForward

Computes the forward FFT.

Syntax

```
status = DftiComputeForward(desc_handle, x_inout);
status = DftiComputeForward(desc_handle, x_in, y_out);
status = DftiComputeForward(desc_handle, xre_inout, xim_inout);
status = DftiComputeForward(desc_handle, xre_in, xim_in, yre_out, yim_out);
```

Input Parameters

Name	Type	Description
<code>desc_handle</code>	<code>DFTI_DESCRIPTOR_HANDLE</code>	FFT descriptor.
<code>x_inout, x_in</code>	Array of type <code>float</code> or <code>double</code> depending on the precision of the transform, specified in the <code>DFTI_PRECISION</code> configuration setting.	Data to be transformed in case of a real forward domain, specified in the <code>DFTI_FORWARD_DOMAIN</code> configuration setting.
<code>xre_inout, xim_inout, xre_in, xim_in</code>	Array of type <code>float</code> or <code>double</code> depending on the precision of the transform.	Real and imaginary parts of the data to be transformed in the case of a complex forward domain, specified in the <code>DFTI_FORWARD_DOMAIN</code> configuration setting.

The suffix in parameter names corresponds to the value of the configuration parameter `DFTI_PLACEMENT` as follows:

- `_inout` to `DFTI_INPLACE`
- `_in` to `DFTI_NOT_INPLACE`

Output Parameters

Name	Type	Description
<code>y_out</code>	Array of type <code>float</code> or <code>double</code> depending on the precision of the transform.	The transformed data in case of a real backward domain, determined by the <code>DFTI_FORWARD_DOMAIN</code> configuration setting.
<code>xre_inout</code> , <code>xim_inout</code> , <code>yre_out</code> , <code>yim_out</code>	Array of type <code>float</code> or <code>double</code> depending on the precision of the transform.	Real and imaginary parts of the transformed data in the case of a complex backward domain, determined by the <code>DFTI_FORWARD_DOMAIN</code> configuration setting.
<code>status</code>	<code>MKL_LONG</code>	Function completion status.

The suffix in parameter names corresponds to the value of the configuration parameter `DFTI_PLACEMENT` as follows:

- `_inout` to `DFTI_INPLACE`
- `_out` to `DFTI_NOT_INPLACE`

Include Files

- `mkl.h`

Description

The `DftiComputeForward` function accepts the descriptor handle parameter and one or more data parameters. Given a successfully configured and committed descriptor, this function computes the forward FFT, that is, the [transform](#) with the minus sign in the exponent, $\delta = -1$.

The `DFTI_COMPLEX_STORAGE`, `DFTI_REAL_STORAGE`, and `DFTI_CONJUGATE_EVEN_STORAGE` configuration parameters define the layout of the input and output data and must be properly set in a call to the `DftiSetValue` function.

The FFT descriptor must be properly configured prior to the function call. Function calls needed to configure an FFT descriptor for a particular call to an FFT computation function are summarized in [Configuring and Computing an FFT in C C++](#).

The number and types of the data parameters that the function requires may vary depending on the configuration of the descriptor. This variation is accommodated by variable parameters.

The function returns zero when it completes successfully. See [Status Checking Functions](#) for more information on the returned status.

Prototype

```
MKL_LONG DftiComputeForward( DFTI_DESCRIPTOR_HANDLE, void*, ... );
```

DftiComputeBackward

Computes the backward FFT.

Syntax

```
status = DftiComputeBackward(desc_handle, x_inout);
```

```
status = DftiComputeBackward(desc_handle, y_in, x_out);
```

```
status = DftiComputeBackward(desc_handle, xre_inout, xim_inout);
```

```
status = DftiComputeBackward(desc_handle, yre_in, yim_in, xre_out, xim_out);
```

Input Parameters

Name	Type	Description
<code>desc_handle</code>	<code>DFTI_DESCRIPTOR_HANDLE</code>	FFT descriptor.
<code>x_inout, y_in</code>	Array of type <code>float</code> or <code>double</code> depending on the precision of the transform, specified in the <code>DFTI_PRECISION</code> configuration setting.	Data to be transformed in case of a real backward domain, determined by the <code>DFTI_FORWARD_DOMAIN</code> configuration setting.
<code>xre_inout, xim_inout, yre_in, yim_in</code>	Array of type <code>float</code> or <code>double</code> depending on the precision of the transform.	Real and imaginary parts of the data to be transformed in the case of a complex backward domain, determined by the <code>DFTI_FORWARD_DOMAIN</code> configuration setting.

The suffix in parameter names corresponds to the value of the configuration parameter `DFTI_PLACEMENT` as follows:

- `_inout` to `DFTI_INPLACE`
- `_in` to `DFTI_NOT_INPLACE`

Output Parameters

Name	Type	Description
<code>x_out</code>	Array of type <code>float</code> or <code>double</code> depending on the precision of the transform.	The transformed data in case of a real forward domain, specified in the <code>DFTI_FORWARD_DOMAIN</code> configuration setting.

Name	Type	Description
<code>xre_inout</code> , <code>xim_inout</code> , <code>xre_out</code> , <code>xim_out</code>	Array of type <code>float</code> or <code>double</code> depending on the precision of the transform.	Real and imaginary parts of the transformed data in the case of a complex forward domain, specified in the <code>DFTI_FORWARD_DOMAIN</code> configuration setting.
<code>status</code>	<code>MKL_LONG</code>	Function completion status.

The suffix in parameter names corresponds to the value of the configuration parameter `DFTI_PLACEMENT` as follows:

- `_inout` to `DFTI_INPLACE`
- `_out` to `DFTI_NOT_INPLACE`

Include Files

- `mkl.h`

Description

The function accepts the descriptor handle parameter and one or more data parameters. Given a successfully configured and committed descriptor, the `DftiComputeBackward` function computes the inverse FFT, that is, the [transform](#) with the plus sign in the exponent, $\delta = +1$.

The `DFTI_COMPLEX_STORAGE`, `DFTI_REAL_STORAGE`, and `DFTI_CONJUGATE_EVEN_STORAGE` configuration parameters define the layout of the input and output data and must be properly set in a call to the `DftiSetValue` function.

The FFT descriptor must be properly configured prior to the function call. Function calls needed to configure an FFT descriptor for a particular call to an FFT computation function are summarized in [Configuring and Computing an FFT in C C++](#).

The number and types of the data parameters that the function requires may vary depending on the configuration of the descriptor. This variation is accommodated by variable parameters.

The function returns zero when it completes successfully. See [Status Checking Functions](#) for more information on the returned status.

Prototype

```
MKL_LONG DftiComputeBackward( DFTI_DESCRIPTOR_HANDLE, void *, ... );
```

Configuring and Computing an FFT in C/C++

The table below summarizes information on configuring and computing an FFT in C/C++ for all kinds of transforms and possible combinations of input and output domains.

FFT to Compute	Input Data	Output Data	Required FFT Function Calls
Complex-to-complex, in-place, forward or backward	Interleaved complex numbers	Interleaved complex numbers	<pre>/* Configure a Descriptor */ status = DftiCreateDescriptor(&hand, <precision>, DFTI_COMPLEX, <dimension>, <sizes>); status = DftiCommitDescriptor(hand); /* Compute an FFT */ /* forward FFT */ status = DftiComputeForward(hand, X_inout); /* or backward FFT */ status = DftiComputeBackward(hand, X_inout);</pre>
Complex-to-complex, out-of-place, forward or backward	Interleaved complex numbers	Interleaved complex numbers	<pre>/* Configure a Descriptor */ status = DftiCreateDescriptor(&hand, <precision>, DFTI_COMPLEX, <dimension>, <sizes>); status = DftiSetValue(hand, DFTI_PLACEMENT, DFTI_NOT_INPLACE); status = DftiCommitDescriptor(hand); /* Compute an FFT */ /* forward FFT */ status = DftiComputeForward(hand, X_in, Y_out); /* or backward FFT */ status = DftiComputeBackward(hand, X_in, Y_out);</pre>
Complex-to-complex, in-place, forward or backward	Split-complex numbers	Split-complex numbers	<pre>/* Configure a Descriptor */ status = DftiCreateDescriptor(&hand, <precision>, DFTI_COMPLEX, <dimension>, <sizes>); status = DftiSetValue(hand, DFTI_COMPLEX_STORAGE, DFTI_REAL_REAL); status = DftiCommitDescriptor(hand); /* Compute an FFT */ /* forward FFT */ status = DftiComputeForward(hand, Xre_inout, Xim_inout); /* or backward FFT */ status = DftiComputeBackward(hand, Xre_inout, Xim_inout);</pre>
Complex-to-complex, out-of-place, forward or backward	Split-complex numbers	Split-complex numbers	<pre>/* Configure a Descriptor */ status = DftiCreateDescriptor(&hand, <precision>, DFTI_COMPLEX, <dimension>, <sizes>); status = DftiSetValue(hand, DFTI_COMPLEX_STORAGE, DFTI_REAL_REAL); status = DftiSetValue(hand, DFTI_PLACEMENT, DFTI_NOT_INPLACE); status = DftiCommitDescriptor(hand); /* Compute an FFT */ /* forward FFT */ status = DftiComputeForward(hand, Xre_in, Xim_in, Yre_out, Yim_out);</pre>

FFT to Compute	Input Data	Output Data	Required FFT Function Calls
			<pre> /* or backward FFT */ status = DftiComputeBackward(hand, Xre_in, Xim_in, Yre_out, Yim_out); </pre>

Complex-to-real, in-place, backward	Numbers in the CCE format	Real numbers	<pre> /* Configure a Descriptor */ status = DftiCreateDescriptor(&hand, <precision>, DFTI_REAL, <dimension>, <sizes>); status = DftiSetValue(hand, DFTI_CONJUGATE_EVEN_STORAGE, DFTI_COMPLEX_COMPLEX); status = DftiSetValue(hand, DFTI_PACKED_FORMAT, DFTI_CCE_FORMAT); status = DftiSetValue(hand, DFTI_INPUT_STRIDES, <complex_strides>); status = DftiSetValue(hand, DFTI_OUTPUT_STRIDES, <real_strides>); status = DftiCommitDescriptor(hand); </pre>

FFT to Compute	Input Data	Output Data	Required FFT Function Calls
Complex-to-real, out-of-place, backward	Numbers in the CCE format	Real numbers	<pre> /* Compute an FFT */ status = DftiComputeBackward(hand, X_inout); /* Configure a Descriptor */ status = DftiCreateDescriptor(&hand, <precision>, DFTI_REAL, <dimension>, <sizes>); status = DftiSetValue(hand, DFTI_CONJUGATE_EVEN_STORAGE, DFTI_COMPLEX_COMPLEX); status = DftiSetValue(hand, DFTI_PLACEMENT, DFTI_NOT_INPLACE); status = DftiSetValue(hand, DFTI_PACKED_FORMAT, DFTI_CCE_FORMAT); status = DftiSetValue(hand, DFTI_INPUT_STRIDES, <complex_strides>); status = DftiSetValue(hand, DFTI_OUTPUT_STRIDES, <real_strides>); status = DftiCommitDescriptor(hand); /* Compute an FFT */ status = DftiComputeBackward(hand, X_in, Y_out); </pre>

You can find C programs that illustrate configuring and computing FFTs in the `examples/dftc/` subdirectory of your Intel MKL directory.

Status Checking Functions

All of the descriptor manipulation, FFT computation, and descriptor configuration functions return an integer value denoting the status of the operation. The functions in this category check that status. The first function is a logical function that checks whether the status reflects an error of a predefined class, and the second is an error message function that returns a character string.

DftiErrorClass

Checks whether the status reflects an error of a predefined class.

Syntax

```
predicate = DftiErrorClass(status, error_class);
```

Include Files

- `mkh.h`

Input Parameters

Name	Type	Description
<code>status</code>	<code>MKL_LONG</code>	Completion status of an FFT function.
<code>error_class</code>	<code>MKL_LONG</code>	Predefined error class.

Output Parameters

Name	Type	Description
<i>predicate</i>	MKL_LONG	Result of checking.

Description

The FFT interface in Intel MKL provides a set of predefined error classes listed in [Table "Predefined Error Classes"](#). They are named constants and have the type `MKL_LONG`.

Predefined Error Classes

Named Constants	Comments
<code>DFTI_NO_ERROR</code>	No error. The zero status belongs to this class.
<code>DFTI_MEMORY_ERROR</code>	Usually associated with memory allocation
<code>DFTI_INVALID_CONFIGURATION</code>	Invalid settings of one or more configuration parameters
<code>DFTI_INCONSISTENT_CONFIGURATION</code>	Inconsistent configuration or input parameters
<code>DFTI_NUMBER_OF_THREADS_ERROR</code>	Number of OMP threads in the computation function is not equal to the number of OMP threads in the initialization stage (commit function)
<code>DFTI_MULTITHREADED_ERROR</code>	Usually associated with a value that OMP routines return in case of errors
<code>DFTI_BAD_DESCRIPTOR</code>	Descriptor is unusable for computation
<code>DFTI_UNIMPLEMENTED</code>	Unimplemented legitimate settings; implementation dependent
<code>DFTI_MKL_INTERNAL_ERROR</code>	Internal library error
<code>DFTI_1D_LENGTH_EXCEEDS_INT32</code>	Length of one of dimensions exceeds $2^{32} - 1$ (4 bytes).

The `DftiErrorClass` function returns a non-zero value if the status belongs to the predefined error class. To check whether a function call was successful, call `DftiErrorClass` with a specific error class. However, the zero value of the status belongs to the `DFTI_NO_ERROR` class and thus the zero status indicates successful completion of an operation. See [Example "Using Status Checking Functions"](#) for an illustration of correct use of the status checking functions.

NOTE

It is incorrect to directly compare a status with a predefined class.

Prototype

```
MKL_LONG DftiErrorClass( MKL_LONG , MKL_LONG );
```

DftiErrorMessage

Generates an error message.

Syntax

```
error_message = DftiErrorMessage(status);
```

Include Files

- `mk1.h`

Input Parameters

Name	Type	Description
<i>status</i>	MKL_LONG	Completion status of a function.

Output Parameters

Name	Type	Description
<i>error_message</i>	Array of <code>char</code>	The character string with the error message.

Description

The error message function generates an error message character string. The function returns a pointer to a constant character string, that is, a character array with terminating '\0' character, and you do not need to free this pointer.

[Example "Using Status Checking Function"](#) shows how this function can be used.

Prototype

```
char *DftiErrorMessage( MKL_LONG );
```

Cluster FFT Functions

This section describes the cluster Fast Fourier Transform (FFT) functions implemented in Intel® MKL.

NOTE

These functions are available only for Intel® 64 and Intel® Many Integrated Core architectures.

The cluster FFT function library was designed to perform fast Fourier transforms on a cluster, that is, a group of computers interconnected via a network. Each computer (node) in the cluster has its own memory and processor(s). Data interchanges between the nodes are provided by the network.

One or more processes may be running in parallel on each cluster node. To organize communication between different processes, the cluster FFT function library uses the Message Passing Interface (MPI). To avoid dependence on a specific MPI implementation (for example, MPICH, Intel® MPI, and others), the library works with MPI via a message-passing library for linear algebra called BLACS.

Cluster FFT functions of Intel MKL provide one-dimensional, two-dimensional, and multi-dimensional (up to the order of 7) functions and both Fortran and C interfaces for all transform functions.

To develop applications using the cluster FFT functions, you should have basic skills in MPI programming.

The interfaces for the Intel MKL cluster FFT functions are similar to the corresponding interfaces for the conventional Intel MKL [FFT functions](#), described earlier in this chapter. Refer there for details not explained in this section.

[Table "Cluster FFT Functions in Intel MKL"](#) lists cluster FFT functions implemented in Intel MKL:

Cluster FFT Functions in Intel MKL

Function Name	Operation
Descriptor Manipulation Functions	
DftiCreateDescriptorDM	Allocates memory for the descriptor data structure and preliminarily initializes it.
DftiCommitDescriptorDM	Performs all initialization for the actual FFT computation.
DftiFreeDescriptorDM	Frees memory allocated for a descriptor.
FFT Computation Functions	
DftiComputeForwardDM	Computes the forward FFT.
DftiComputeBackwardDM	Computes the backward FFT.
Descriptor Configuration Functions	
DftiSetValueDM	Sets one particular configuration parameter with the specified configuration value.
DftiGetValueDM	Gets the value of one particular configuration parameter.

Computing Cluster FFT

The cluster FFT functions described later in this section are provided with Fortran and C interfaces.

Cluster FFT computation is performed by [DftiComputeForwardDM](#) and [DftiComputeBackwardDM](#) functions, called in a program using MPI, which will be referred to as MPI program. After an MPI program starts, a number of processes are created. MPI identifies each process by its rank. The processes are independent of one another and communicate via MPI. A function called in an MPI program is invoked in all the processes. Each process manipulates data according to its rank. Input or output data for a cluster FFT transform is a sequence of real or complex values. A cluster FFT computation function operates on the local part of the input data, that is, some part of the data to be operated in a particular process, as well as generates local part of the output data. While each process performs its part of computations, running in parallel and communicating through MPI, the processes perform the entire FFT computation. FFT computations using the Intel MKL cluster FFT functions are typically effected by a number of steps listed below:

1. Initiate MPI by calling `MPI_Init` (the function must be called prior to calling any FFT function and any MPI function).
2. Allocate memory for the descriptor and create it by calling [DftiCreateDescriptorDM](#).
3. Specify one of several values of configuration parameters by one or more calls to [DftiSetValueDM](#).
4. Obtain values of configuration parameters needed to create local data arrays; the values are retrieved by calling [DftiGetValueDM](#).
5. Initialize the descriptor for the FFT computation by calling [DftiCommitDescriptorDM](#).
6. Create arrays for local parts of input and output data and fill the local part of input data with values. (For more information, see [Distributing Data among Processes](#).)
7. Compute the transform by calling [DftiComputeForwardDM](#) or [DftiComputeBackwardDM](#).
8. Gather local output data into the global array using MPI functions. (This step is optional because you may need to immediately employ the data differently.)
9. Release memory allocated for the descriptor by calling [DftiFreeDescriptorDM](#).
10. Finalize communication through MPI by calling `MPI_Finalize` (the function must be called after the last call to a cluster FFT function and the last call to an MPI function).

Several code examples in the "[Examples for Cluster FFT Functions](#)" section in the Code Examples appendix illustrate cluster FFT computations.

Distributing Data among Processes

The Intel MKL cluster FFT functions store all input and output multi-dimensional arrays (matrices) in one-dimensional arrays (vectors). The arrays are stored in the row-major order. For example, a two-dimensional matrix A of size (m,n) is stored in a vector B of size $m*n$ so that

$B[i*n+j]=A[i][j]$ ($i=0, \dots, m-1, j=0, \dots, n-1$).

NOTE

Order of FFT dimensions is the same as the order of array dimensions in the programming language. For example, a 3-dimensional FFT with Lengths= (m,n,l) can be computed over an array $Ar[m][n][l]$.

All MPI processes involved in cluster FFT computation operate their own portions of data. These local arrays make up the virtual global array that the fast Fourier transform is applied to. It is your responsibility to properly allocate local arrays (if needed), fill them with initial data and gather resulting data into an actual global array or process the resulting data differently. To be able to do this, see sections below on how the virtual global array is composed of the local ones.

Multi-dimensional transforms

If the dimension of transform is greater than one, the cluster FFT function library splits data in the dimension whose index changes most slowly, so that the parts contain all elements with several consecutive values of this index. It is the first dimension in C . If the global array is two-dimensional, it gives each process several consecutive rows. Local arrays are placed in memory allocated for the virtual global array consecutively, in the order determined by process ranks. For example, in case of two processes, during the computation of a three-dimensional transform whose matrix has size $(11,15,12)$, the processes may store local arrays of sizes $(6,15,12)$ and $(5,15,12)$, respectively.

If p is the number of MPI processes and the matrix of a transform to be computed has size (m,n,l) , each MPI process works with local data array of size (m_q, n, l) , where $\sum m_q = m$, $q=0, \dots, p-1$. Local input arrays must contain appropriate parts of the actual global input array, and then local output arrays will contain appropriate parts of the actual global output array. You can figure out which particular rows of the global array the local array must contain from the following configuration parameters of the cluster FFT interface: `CDFT_LOCAL_NX`, `CDFT_LOCAL_START_X`, and `CDFT_LOCAL_SIZE`. To retrieve values of the parameters, use the `DftiGetValueDM` function:

- `CDFT_LOCAL_NX` specifies how many rows of the global array the current process receives.
- `CDFT_LOCAL_START_X` specifies which row of the global input or output array corresponds to the first row of the local input or output array. If A is a global array and L is the appropriate local array, then

$L[i][j][k]=A[i+cdft\_local\_start\_x][j][k]$, where $i=0, \dots, m_q-1, j=0, \dots, n-1, k=0, \dots, l-1$.

Example "2D Out-of-place Cluster FFT Computation" in the [Code Examples appendix](#) shows how the data is distributed among processes for a two-dimensional cluster FFT computation.

One-dimensional transforms

In this case, input and output data are distributed among processes differently and even the numbers of elements stored in a particular process before and after the transform may be different. Each local array stores a segment of consecutive elements of the appropriate global array. Such segment is determined by the number of elements and a shift with respect to the first array element. So, to specify segments of the global input and output arrays that a particular process receives, four configuration parameters are needed: `CDFT_LOCAL_NX`, `CDFT_LOCAL_START_X`, `CDFT_LOCAL_OUT_NX`, and `CDFT_LOCAL_OUT_START_X`. Use the `DftiGetValueDM` function to retrieve their values. The meaning of the four configuration parameters depends upon the type of the transform, as shown in [Table "Data Distribution Configuration Parameters for 1D Transforms"](#):

Data Distribution Configuration Parameters for 1D Transforms

Meaning of the Parameter	Forward Transform	Backward Transform
Number of elements in input array	CDFT_LOCAL_NX	CDFT_LOCAL_OUT_NX
Elements shift in input array	CDFT_LOCAL_START_X	CDFT_LOCAL_OUT_START_X
Number of elements in output array	CDFT_LOCAL_OUT_NX	CDFT_LOCAL_NX
Elements shift in output array	CDFT_LOCAL_OUT_START_X	CDFT_LOCAL_START_X

Memory size for local data

The memory size needed for local arrays cannot be just calculated from `CDFT_LOCAL_NX` (`CDFT_LOCAL_OUT_NX`), because the cluster FFT functions sometimes require allocating a little bit more memory for local data than just the size of the appropriate sub-array. The configuration parameter `CDFT_LOCAL_SIZE` specifies the size of the local input and output array in data elements. Each local input and output arrays must have size not less than `CDFT_LOCAL_SIZE*size_of_element`. Note that in the current implementation of the cluster FFT interface, data elements can be real or complex values, each complex value consisting of the real and imaginary parts. If you employ a user-defined workspace for in-place transforms (for more information, refer to [Table "Settable configuration Parameters"](#)), it must have the same size as the local arrays. [Example "1D In-place Cluster FFT Computations"](#) in the Code Examples appendix illustrates how the cluster FFT functions distribute data among processes in case of a one-dimensional FFT computation performed with a user-defined workspace.

Available Auxiliary Functions

If a global input array is located on one MPI process and you want to obtain its local parts or you want to gather the global output array on one MPI process, you can use functions `MKL_CDFT_ScatterData` and `MKL_CDFT_GatherData` to distribute or gather data among processes, respectively. These functions are defined in a file that is delivered with Intel MKL and located in the following subdirectory of the Intel MKL installation directory: `examples/cdftc/source/cdft_example_support.c`.

Restriction on Lengths of Transforms

The algorithm that the Intel MKL cluster FFT functions use to distribute data among processes imposes a restriction on lengths of transforms with respect to the number of MPI processes used for the FFT computation:

- For a multi-dimensional transform, lengths of the first two dimensions must be not less than the number of MPI processes.
- Length of a one-dimensional transform must be the product of two integers each of which is not less than the number of MPI processes.

Non-compliance with the restriction causes an error `CDFT_SPREAD_ERROR` (refer to [Error Codes](#) for details). To achieve the compliance, you can change the transform lengths and/or the number of MPI processes, which is specified at start of an MPI program. MPI-2 enables changing the number of processes during execution of an MPI program.

Cluster FFT Interface

To use the cluster FFT functions, you need to access the header file `mkl_cdft.h` through `"include"`.

The C interface provides a structure type `DFTI_DESCRIPTOR_DM_HANDLE` and a number of functions, some of which accept a different number of input arguments.

To provide communication between parallel processes through MPI, the following include statement must be present in your code:

- C/C++:

```
#include "mpi.h"
```

There are three main categories of the cluster FFT functions in Intel MKL:

1. **Descriptor Manipulation** . There are three functions in this category. The [DftiCreateDescriptorDM](#) function creates an FFT descriptor whose storage is allocated dynamically. The [DftiCommitDescriptorDM](#) function "commits" the descriptor to all its settings. The [DftiFreeDescriptorDM](#) function frees up the memory allocated for the descriptor.
2. **FFT Computation** . There are two functions in this category. The [DftiComputeForwardDM](#) function performs the forward FFT computation, and the [DftiComputeBackwardDM](#) function performs the backward FFT computation.
3. **Descriptor Configuration** . There are two functions in this category. The [DftiSetValueDM](#) function sets one specific configuration value to one of the many configuration parameters. The [DftiGetValueDM](#) function gets the current value of any of these configuration parameters, all of which are readable. These parameters, though many, are handled one at a time.

Descriptor Manipulation Functions

There are three functions in this category: create a descriptor, commit a descriptor, and free a descriptor.

DftiCreateDescriptorDM

Allocates memory for the descriptor data structure and preliminarily initializes it.

Syntax

```
status = DftiCreateDescriptorDM(comm, &handle, v1, v2, dim, size );
status = DftiCreateDescriptorDM(comm, &handle, v1, v2, dim, sizes );
```

Include Files

- mkl_cdft.h

Input Parameters

<i>comm</i>	MPI communicator, e.g. MPI_COMM_WORLD.
<i>v1</i>	Precision of the transform.
<i>v2</i>	Type of the forward domain. Must be DFTI_COMPLEX for complex-to-complex transforms or DFTI_REAL for real-to-complex transforms.
<i>dim</i>	Dimension of the transform.
<i>size</i>	Length of the transform in a one-dimensional case.
<i>sizes</i>	Lengths of the transform in a multi-dimensional case.

Output Parameters

<i>handle</i>	Pointer to the descriptor handle of transform. If the function completes successfully, the pointer to the created handle is stored in the variable.

Description

This function allocates memory in a particular MPI process for the descriptor data structure and instantiates it with default configuration settings with respect to the precision, domain, dimension, and length of the desired transform. The domain is understood to be the domain of the forward transform. The result is a pointer to the created descriptor. This function is slightly different from the "initialization" function [DftiCommitDescriptorDM](#) in a more traditional software packages or libraries used for computing the FFT. This function does not perform any significant computation work, such as twiddle factors computation, because the default configuration settings can still be changed using the function [DftiSetValueDM](#).

The value of the parameter *vt* is specified through named constants `DFTI_SINGLE` and `DFTI_DOUBLE`. It corresponds to precision of input data, output data, and computation. A setting of `DFTI_SINGLE` indicates single-precision floating-point data type and a setting of `DFTI_DOUBLE` indicates double-precision floating-point data type.

The parameter *dim* is a simple positive integer indicating the dimension of the transform.

For one-dimensional transforms, length is a single integer value of the parameter *size* having type `MKL_LONG`; for multi-dimensional transforms, length is supplied with the parameter *sizes*, which is an array of integers having type `MKL_LONG`.

Return Values

The function returns `DFTI_NO_ERROR` when completes successfully. In this case, the pointer to the created descriptor handle is stored in *handle*. If the function fails, it returns a value of another error class constant

Prototype

```
MKL_LONG DftiCreateDescriptorDM(MPI_Comm,DFTI_DESCRIPTOR_DM_HANDLE*,
    enum DFTI_CONFIG_VALUE,enum DFTI_CONFIG_VALUE,MKL_LONG,...);
```

DftiCommitDescriptorDM

Performs all initialization for the actual FFT computation.

Syntax

```
status = DftiCommitDescriptorDM(handle);
```

Include Files

- `mkl_cdft.h`

Input Parameters

handle The descriptor handle. Must be valid, that is, created in a call to [DftiCreateDescriptorDM](#).

Description

The cluster FFT interface requires a function that completes initialization of a previously created descriptor before the descriptor can be used for FFT computations in a particular MPI process. The [DftiCommitDescriptorDM](#) function performs all initialization that facilitates the actual FFT computation. For the current implementation, it may involve exploring many different factorizations of the input length to search for highly efficient computation method.

Any changes of configuration parameters of a committed descriptor via the set value function (see [Descriptor Configuration Functions](#)) requires a re-committal of the descriptor before a computation function can be invoked. Typically, this committal function is called right before a computation function call (see [FFT Computation Functions](#)).

Return Values

The function returns `DFTI_NO_ERROR` when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to the [Error Codes](#) section).

Prototype

```

MKL_LONG DftiCommitDescriptorDM(DFTI_DESCRIPTOR_DM_HANDLE handle);

```

DftiFreeDescriptorDM

Frees memory allocated for a descriptor.

Syntax

```
status = DftiFreeDescriptorDM(&handle);
```

Include Files

- mkl cdft.h

Input Parameters

handle The descriptor handle. Must be valid, that is, created in a call to `DftiCreateDescriptorDM`.

Output Parameters

<i>handle</i>	The descriptor handle. Memory allocated for the handle is released on output.

Description

This function frees up all memory allocated for a descriptor in a particular MPI process. Call the `DftiFreeDescriptorDM` function to delete the descriptor handle. Upon successful completion of `DftiFreeDescriptorDM` the descriptor handle is no longer valid.

Return Values

The function returns `DFTI_NO_ERROR` when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to the [Error Codes](#) section).

Prototype

```

MKL_LONG DftiFreeDescriptorDM(DFTI_DESCRIPTOR_DM_HANDLE *handle);

```

FFT Computation Functions

There are two functions in this category: compute the forward transform and compute the backward transform.

DftiComputeForwardDM

Computes the forward FFT.

Syntax

```
status = DftiComputeForwardDM(handle, in X, out X);
```

```
status = DftiComputeForwardDM(handle, in_out_X);
```

Include Files

- `mkl_cdft.h`

Input Parameters

handle The descriptor handle.

in_X, in_out_X Local part of input data. Array of complex values. Refer to the [Distributing Data among Processes](#) section on how to allocate and initialize the array.

Output Parameters

out_X, in_out_X Local part of output data. Array of complex values. Refer to the [Distributing Data among Processes](#) section on how to allocate the array.

Description

The `DftiComputeForwardDM` function computes the forward FFT. Forward FFT is the transform using the factor $e^{-i2\pi/n}$.

Before you call the function, the valid descriptor, created by `DftiCreateDescriptorDM`, must be configured and committed using the `DftiCommitDescriptorDM` function.

The computation is carried out by calling the `DftiComputeForward` function. So, the functions have very much in common, and details not explicitly mentioned below can be found in the description of `DftiComputeForward`.

Local part of input data, as well as local part of the output data, is an appropriate sequence of complex values (each complex value consists of two real numbers: real part and imaginary part) that a particular process stores. See the [Distributing Data Among Processes](#) section for details.

Refer to the [Configuration Settings](#) section for the list of configuration parameters that the descriptor passes to the function.

The configuration parameter `DFTI_PRECISION` determines the precision of input data, output data, and transform: a setting of `DFTI_SINGLE` indicates single-precision floating-point data type and a setting of `DFTI_DOUBLE` indicates double-precision floating-point data type.

The configuration parameter `DFTI_PLACEMENT` informs the function whether the computation should be in-place. If the value of this parameter is `DFTI_INPLACE` (default), you must call the function with two parameters, otherwise you must supply three parameters. If `DFTI_PLACEMENT = DFTI_INPLACE` and three parameters are supplied, then the third parameter is ignored.

CAUTION

Even in case of an out-of-place transform, local array of input data *in_X* may be changed. To save data, make its copy before calling `DftiComputeForwardDM`.

In case of an in-place transform, `DftiComputeForwardDM` dynamically allocates and deallocates a work buffer of the same size as the local input/output array requires.

NOTE

You can specify your own workspace of the same size through the configuration parameter `CDFT_WORKSPACE` to avoid redundant memory allocation.

Return Values

The function returns `DFTI_NO_ERROR` when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to the [Error Codes](#) section).

Prototype

```
MKL_LONG DftiComputeForwardDM(DFTI_DESCRIPTOR_DM_HANDLE handle, void *in_X,...);
```

DftiComputeBackwardDM

Computes the backward FFT.

Syntax

```
status = DftiComputeBackwardDM(handle, in_X, out_X);
```

```
status = DftiComputeBackwardDM(handle, in_out_X);
```

Include Files

- `mkl_cdft.h`

Input Parameters

<i>handle</i>	The descriptor handle.
<i>in_X, in_out_X</i>	Local part of input data. Array of complex values. Refer to the Distributing Data among Processes section on how to allocate and initialize the array.

Output Parameters

<i>out_X, in_out_X</i>	Local part of output data. Array of complex values. Refer to the Distributing Data among Processes section on how to allocate the array.

Description

The `DftiComputeBackwardDM` function computes the backward FFT. Backward FFT is the transform using the factor $e^{i2\pi/n}$.

Before you call the function, the valid descriptor, created by `DftiCreateDescriptorDM`, must be configured and committed using the `DftiCommitDescriptorDM` function.

The computation is carried out by calling the `DftiComputeBackward` function. So, the functions have very much in common, and details not explicitly mentioned below can be found in the description of `DftiComputeBackward`.

Local part of input data, as well as local part of the output data, is an appropriate sequence of complex values (each complex value consists of two real numbers: real part and imaginary part) that a particular process stores. See the [Distributing Data among Processes](#) section for details.

Refer to the [Configuration Settings](#) section for the list of configuration parameters that the descriptor passes to the function.

The configuration parameter `DFTI_PRECISION` determines the precision of input data, output data, and transform: a setting of `DFTI_SINGLE` indicates single-precision floating-point data type and a setting of `DFTI_DOUBLE` indicates double-precision floating-point data type.

The configuration parameter `DFTI_PLACEMENT` informs the function whether the computation should be in-place. If the value of this parameter is `DFTI_INPLACE` (default), you must call the function with two parameters, otherwise you must supply three parameters. If `DFTI_PLACEMENT = DFTI_INPLACE` and three parameters are supplied, then the third parameter is ignored.

CAUTION

Even in case of an out-of-place transform, local array of input data `in_X` may be changed. To save data, make its copy before calling `DftiComputeBackwardDM`.

In case of an in-place transform, `DftiComputeBackwardDM` dynamically allocates and deallocates a work buffer of the same size as the local input/output array requires.

NOTE

You can specify your own workspace of the same size through the configuration parameter `CDFT_WORKSPACE` to avoid redundant memory allocation.

Return Values

The function returns `DFTI_NO_ERROR` when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to the [Error Codes](#) section).

Prototype

```
MKL_LONG DftiComputeBackwardDM(DFTI_DESCRIPTOR_DM_HANDLE handle, void *in_X,...);
```

Descriptor Configuration Functions

There are two functions in this category: the value setting function `DftiSetValueDM` sets one particular configuration parameter to an appropriate value, the value getting function `DftiGetValueDM` reads the value of one particular configuration parameter.

Some configuration parameters used by cluster FFT functions originate from the conventional FFT interface (see [Configuration Settings](#) subsection in the "FFT Functions" section for details).

Other configuration parameters are specific to the cluster FFT. Integer values of these parameters have type `MKL_LONG`. The exact type of the configuration parameters being floating-point scalars is `float` or `double`. The configuration parameters whose values are named constants have the `enum` type. They are defined in the `mkl_cdft.h` header file.

Names of the configuration parameters specific to the cluster FFT interface have prefix `CDFT`.

DftiSetValueDM

Sets one particular configuration parameter with the specified configuration value.

Syntax

```
status = DftiSetValueDM (handle, param, value);
```

Include Files

- `mkl_cdft.h`

Input Parameters

<i>handle</i>	The descriptor handle. Must be valid, that is, created in a call to DftiCreateDescriptorDM .
<i>param</i>	Name of a parameter to be set up in the descriptor handle. See Table "Settable Configuration Parameters" for the list of available parameters.
<i>value</i>	Value of the parameter.

Description

This function sets one particular configuration parameter with the specified configuration value. The configuration parameter is one of the named constants listed in the table below, and the configuration value must have the corresponding type. See [Configuration Settings](#) for details of the meaning of each setting and for possible values of the parameters whose values are named constants.

Settable Configuration Parameters

Parameter Name	Data Type	Description	Default Value
DFTI_FORWARD_SCALE	Floating-point scalar	Scale factor of forward transform.	1.0
DFTI_BACKWARD_SCALE	Floating-point scalar	Scale factor of backward transform.	1.0
DFTI_PLACEMENT	Named constant	Placement of the computation result.	DFTI_INPLACE
DFTI_ORDERING	Named constant	Scrambling of data order.	DFTI_ORDERED
CDFT_WORKSPACE	Array of an appropriate type	Auxiliary buffer, a user-defined workspace. Enables saving memory during in-place computations.	NULL (allocate workspace dynamically).
DFTI_PACKED_FORMAT	Named constant	Packed format, real data.	- DFTI_PERM_FORMAT — default and the only available value for one-dimensional transforms - DFTI_CCE_FORMAT — default and the only available value for multi-dimensional transforms
DFTI_TRANSPOSE	Named constant	This parameter determines how the output data is located for multi-dimensional transforms. If the parameter value is DFTI_NONE, the data is located in a usual manner described in this manual. If the value is DFTI_ALLOW, the last (first) global transposition is not performed for a forward (backward) transform.	DFTI_NONE

Return Values

The function returns `DFTI_NO_ERROR` when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to the [Error Codes](#) section).

Prototype

```
MKL_LONG DftiSetValueDM(DFTI_DESCRIPTOR_DM_HANDLE handle, int param,...);
```

DftiGetValueDM

Gets the value of one particular configuration parameter.

Syntax

```
status = DftiGetValueDM(handle, param, &value);
```

Include Files

- `mkl_cdft.h`

Input Parameters

handle

The descriptor handle. Must be valid, that is, created in a call to [DftiCreateDescriptorDM](#).

param

Name of a parameter to be retrieved from the descriptor. See [Table "Retrievable Configuration Parameters"](#) for the list of available parameters.

Output Parameters

value

Value of the parameter.

Description

This function gets the configuration value of one particular configuration parameter. The configuration parameter is one of the named constants listed in the table below, and the configuration value is the corresponding appropriate type, which can be a named constant or a native type. Possible values of the named constants can be found in [Table "Configuration Parameters"](#) and relevant subsections of the [Configuration Settings](#) section.

Retrievable Configuration Parameters

Parameter Name	Data Type	Description
<code>DFTI_PRECISION</code>	Named constant	Precision of computation, input data and output data.
<code>DFTI_DIMENSION</code>	Integer scalar	Dimension of the transform
<code>DFTI_LENGTHS</code>	Array of integer values	Array of lengths of the transform. Number of lengths corresponds to the dimension of the transform.
<code>DFTI_FORWARD_SCALE</code>	Floating-point scalar	Scale factor of forward transform.
<code>DFTI_BACKWARD_SCALE</code>	Floating-point scalar	Scale factor of backward transform.
<code>DFTI_PLACEMENT</code>	Named constant	Placement of the computation result.

Parameter Name	Data Type	Description
DFTI_COMMIT_STATUS	Named constant	Shows whether descriptor has been committed.
DFTI_FORWARD_DOMAIN	Named constant	Forward domain of transforms, has the value of <code>DFTI_COMPLEX</code> or <code>DFTI_REAL</code> .
DFTI_ORDERING	Named constant	Scrambling of data order.
CDFT_MPI_COMM	Type of MPI communicator	MPI communicator used for transforms.
CDFT_LOCAL_SIZE	Integer scalar	Necessary size of input, output, and buffer arrays in data elements.
CDFT_LOCAL_X_START	Integer scalar	Row/element number of the global array that corresponds to the first row/element of the local array. For more information, see Distributing Data among Processes .
CDFT_LOCAL_NX	Integer scalar	The number of rows/elements of the global array stored in the local array. For more information, see Distributing Data among Processes .
CDFT_LOCAL_OUT_X_START	Integer scalar	Element number of the appropriate global array that corresponds to the first element of the input or output local array in a 1D case. For details, see Distributing Data among Processes .
CDFT_LOCAL_OUT_NX	Integer scalar	The number of elements of the appropriate global array that are stored in the input or output local array in a 1D case. For details, see Distributing Data among Processes .

Return Values

The function returns `DFTI_NO_ERROR` when completes successfully. If the function fails, it returns a value of another error class constant (for the list of constants, refer to the [Error Codes](#) section).

Prototype

```
MKL_LONG DftiGetValueDM(DFTI_DESCRIPTOR_DM_HANDLE handle, int param,...);
```

Error Codes

All the cluster FFT functions return an integer value denoting the status of the operation. These values are identified by named constants. Each function returns `DFTI_NO_ERROR` if no errors were encountered during execution. Otherwise, a function generates an error code. In addition to FFT error codes, the cluster FFT interface has its own ones. Named constants specific to the cluster FFT interface have prefix "CDFT" in names. [Table "Error Codes that Cluster FFT Functions Return"](#) lists error codes that the cluster FFT functions may return.

Error Codes that Cluster FFT Functions Return

Named Constants	Comments
DFTI_NO_ERROR	No error.
DFTI_MEMORY_ERROR	Usually associated with memory allocation.
DFTI_INVALID_CONFIGURATION	Invalid settings of one or more configuration parameters.
DFTI_INCONSISTENT_CONFIGURATION	Inconsistent configuration or input parameters.
DFTI_NUMBER_OF_THREADS_ERROR	Number of OMP threads in the computation function is not equal to the number of OMP threads in the initialization stage (commit function).
DFTI_MULTITHREADED_ERROR	Usually associated with a value that OMP routines return in case of errors.
DFTI_BAD_DESCRIPTOR	Descriptor is unusable for computation.
DFTI_UNIMPLEMENTED	Unimplemented legitimate settings; implementation dependent.
DFTI_MKL_INTERNAL_ERROR	Internal library error.
DFTI_1D_LENGTH_EXCEEDS_INT32	Length of one of dimensions exceeds $2^{32} - 1$ (4 bytes).
CDFT_SPREAD_ERROR	Data cannot be distributed (For more information, see Distributing Data among Processes.)
CDFT_MPI_ERROR	MPI error. Occurs when calling MPI.

PBLAS Routines

This chapter describes the Intel® Math Kernel Library implementation of the PBLAS (Parallel Basic Linear Algebra Subprograms) routines from the ScaLAPACK package for distributed-memory architecture. PBLAS is intended for using in vector-vector, matrix-vector, and matrix-matrix operations to simplify the parallelization of linear codes. The design of PBLAS is as consistent as possible with that of the BLAS. The routine descriptions are arranged in several sections according to the PBLAS level of operation:

- [PBLAS Level 1 Routines](#) (distributed vector-vector operations)
- [PBLAS Level 2 Routines](#) (distributed matrix-vector operations)
- [PBLAS Level 3 Routines](#) (distributed matrix-matrix operations)

Each section presents the routine and function group descriptions in alphabetical order by the routine group name; for example, the `p?asum` group, the `p?axpy` group. The question mark in the group name corresponds to a character indicating the data type (`s`, `d`, `c`, and `z` or their combination); see [Routine Naming Conventions](#).

NOTE

PBLAS routines are provided only with Intel® MKL versions for Linux* and Windows* OSs.

Generally, PBLAS runs on a network of computers using MPI as a message-passing layer and a set of prebuilt communication subprograms (BLACS), as well as a set of PBLAS optimized for the target architecture. The Intel MKL version of PBLAS is optimized for Intel® processors. For the detailed system and environment requirements see *Intel® MKL Release Notes* and *Intel® MKL User's Guide*.

For full reference on PBLAS routines and related information, see http://www.netlib.org/scalapack/html/pblas_qref.html.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Overview

The model of the computing environment for PBLAS is represented as a one-dimensional array of processes or also a two-dimensional process grid. To use PBLAS, all global matrices or vectors must be distributed on this array or grid prior to calling the PBLAS routines.

PBLAS uses the two-dimensional block-cyclic data distribution as a layout for dense matrix computations. This distribution provides good work balance between available processors, as well as gives the opportunity to use PBLAS Level 3 routines for optimal local computations. Information about the data distribution that is required to establish the mapping between each global array and its corresponding process and memory location is contained in the so called *array descriptor* associated with each global array. [Table "Content of the array descriptor for dense matrices"](#) gives an example of an array descriptor structure.

Content of Array Descriptor for Dense Matrices

Array Element #	Name	Definition
1	<i>dtype</i>	Descriptor type (=1 for dense matrices)
2	<i>ctxt</i>	BLACS context handle for the process grid
3	<i>m</i>	Number of rows in the global array
4	<i>n</i>	Number of columns in the global array
5	<i>mb</i>	Row blocking factor
6	<i>nb</i>	Column blocking factor
7	<i>rsrc</i>	Process row over which the first row of the global array is distributed
8	<i>csrc</i>	Process column over which the first column of the global array is distributed
9	<i>lld</i>	Leading dimension of the local array

The number of rows and columns of a global dense matrix that a particular process in a grid receives after data distributing is denoted by *LOCr()* and *LOCc()*, respectively. To compute these numbers, you can use the ScaLAPACK tool routine *numroc*.

After the block-cyclic distribution of global data is done, you may choose to perform an operation on a submatrix of the global matrix *A*, which is contained in the global subarray *sub(A)*, defined by the following 6 values (for dense matrices):

<i>m</i>	The number of rows of <i>sub(A)</i>
<i>n</i>	The number of columns of <i>sub(A)</i>
<i>a</i>	A pointer to the local array containing the entire global array <i>A</i>
<i>ia</i>	The row index of <i>sub(A)</i> in the global array
<i>ja</i>	The column index of <i>sub(A)</i> in the global array
<i>desca</i>	The array descriptor for the global array <i>A</i>

Intel MKL provides the PBLAS routines with interface similar to the interface used in the Netlib PBLAS (see http://www.netlib.org/scalapack/html/pblas_qref.html).

Routine Naming Conventions

The naming convention for PBLAS routines is similar to that used for BLAS routines (see [Routine Naming Conventions in Chapter 2](#)). A general rule is that each routine name in PBLAS, which has a BLAS equivalent, is simply the BLAS name prefixed by initial letter *p* that stands for "parallel".

The Intel MKL PBLAS routine names have the following structure:

```
p <character> <name> <mod> ( )
```

The *<character>* field indicates the Fortran data type:

s	real, single precision
c	complex, single precision
d	real, double precision
z	complex, double precision
i	integer

Some routines and functions can have combined character codes, such as *sc* or *dz*.

For example, the function *pzcasum* uses a complex input array and returns a real value.

The *<name>* field, in PBLAS level 1, indicates the operation type. For example, the PBLAS level 1 routines *p?dot*, *p?swap*, *p?copy* compute a vector dot product, vector swap, and a copy vector, respectively.

In PBLAS level 2 and 3, *<name>* reflects the matrix argument type:

<i>ge</i>	general matrix
<i>sy</i>	symmetric matrix
<i>he</i>	Hermitian matrix
<i>tr</i>	triangular matrix

In PBLAS level 3, the *<name>=tran* indicates the transposition of the matrix.

The *<mod>* field, if present, provides additional details of the operation. The PBLAS level 1 names can have the following characters in the *<mod>* field:

<i>c</i>	conjugated vector
<i>u</i>	unconjugated vector

The PBLAS level 2 names can have the following additional characters in the *<mod>* field:

<i>mv</i>	matrix-vector product
<i>sv</i>	solving a system of linear equations with matrix-vector operations
<i>r</i>	rank-1 update of a matrix
<i>r2</i>	rank-2 update of a matrix.

The PBLAS level 3 names can have the following additional characters in the *<mod>* field:

<i>mm</i>	matrix-matrix product
<i>sm</i>	solving a system of linear equations with matrix-matrix operations
<i>rk</i>	rank- <i>k</i> update of a matrix
<i>r2k</i>	rank-2 <i>k</i> update of a matrix.

The examples below show how to interpret PBLAS routine names:

<i>pddot</i>	<i><p> <d> <dot></i> : double-precision real distributed vector-vector dot product
<i>pcdotc</i>	<i><p> <c> <dot> <c></i> : complex distributed vector-vector dot product, conjugated
<i>pscsum</i>	<i><p> <sc> <asum></i> : sum of magnitudes of distributed vector elements, single precision real output and single precision complex input
<i>pcdotu</i>	<i><p> <c> <dot> <u></i> : distributed vector-vector dot product, unconjugated, complex
<i>psgemv</i>	<i><p> <s> <ge> <mv></i> : distributed matrix-vector product, general matrix, single precision
<i>pztrmm</i>	<i><p> <z> <tr> <mm></i> : distributed matrix-matrix product, triangular matrix, double-precision complex.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

PBLAS Level 1 Routines

PBLAS Level 1 includes routines and functions that perform distributed vector-vector operations. [Table "PBLAS Level 1 Routine Groups and Their Data Types"](#) lists the PBLAS Level 1 routine groups and the data types associated with them.

PBLAS Level 1 Routine Groups and Their Data Types

Routine or Function Group	Data Types	Description
p?amax	s, d, c, z	Calculates an index of the distributed vector element with maximum absolute value
p?asum	s, d, sc, dz	Calculates sum of magnitudes of a distributed vector
p?axpy	s, d, c, z	Calculates distributed vector-scalar product
p?copy	s, d, c, z	Copies a distributed vector
p?dot	s, d	Calculates a dot product of two distributed real vectors
p?dotc	c, z	Calculates a dot product of two distributed complex vectors, one of them is conjugated
p?dotu	c, z	Calculates a dot product of two distributed complex vectors
p?nrm2	s, d, sc, dz	Calculates the 2-norm (Euclidean norm) of a distributed vector
p?scal	s, d, c, z, cs, zd	Calculates a product of a distributed vector by a scalar
p?swap	s, d, c, z	Swaps two distributed vectors

[p?amax](#)

Computes the global index of the element of a distributed vector with maximum absolute value.

Syntax

```
void psamax (MKL_INT *n , float *amax , MKL_INT *indx , float *x , MKL_INT *ix ,
MKL_INT *jx , MKL_INT *descx , MKL_INT *incx );

void pdamax (MKL_INT *n , double *amax , MKL_INT *indx , double *x , MKL_INT *ix ,
MKL_INT *jx , MKL_INT *descx , MKL_INT *incx );

void pcamax (MKL_INT *n , float *amax , MKL_INT *indx , float *x , MKL_INT *ix ,
MKL_INT *jx , MKL_INT *descx , MKL_INT *incx );
```

```
void pzamax (MKL_INT *n , double *amax , MKL_INT *indx , double *x , MKL_INT *ix ,
MKL_INT *jx , MKL_INT *descx , MKL_INT *incx );
```

Include Files

- mkl_pblas.h

Description

The functions `p?amax` compute global index of the maximum element in absolute value of a distributed vector `sub(x)`,

where `sub(x)` denotes $X(ix, jx:jx+n-1)$ if $incx=m_x$, and $X(ix: ix+n-1, jx)$ if $incx= 1$.

Input Parameters

<code>n</code>	(global) The length of distributed vector <code>sub(x)</code> , $n \geq 0$.
<code>x</code>	(local) Array, size $(jx-1) * m_x + ix + (n-1) * \text{abs}(incx)$. This array contains the entries of the distributed vector <code>sub(x)</code> .
<code>ix, jx</code>	(global) The row and column indices in the distributed matrix X indicating the first row and the first column of the submatrix <code>sub(X)</code> , respectively.
<code>descx</code>	(global and local) array of dimension 9. The array descriptor of the distributed matrix X .
<code>incx</code>	(global) Specifies the increment for the elements of <code>sub(x)</code> . Only two values are supported, namely 1 and m_x . <code>incx</code> must not be zero.

Output Parameters

<code>amax</code>	(global). Maximum absolute value (magnitude) of elements of the distributed vector only in its scope.
<code>indx</code>	(global) The global index of the maximum element in absolute value of the distributed vector <code>sub(x)</code> only in its scope.

p?asum

Computes the sum of magnitudes of elements of a distributed vector.

Syntax

```
void psasum (MKL_INT *n , float *asum , float *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx );
```

```
void pdasum (MKL_INT *n , double *asum , double *x , MKL_INT *ix , MKL_INT *jx ,
MKL_INT *descx , MKL_INT *incx );
```

```
void pscasum (MKL_INT *n , float *asum , float *x , MKL_INT *ix , MKL_INT *jx ,
MKL_INT *descx , MKL_INT *incx );
```

```
void pdzasum (MKL_INT *n , double *asum , double *x , MKL_INT *ix , MKL_INT *jx ,
MKL_INT *descx , MKL_INT *incx );
```

Include Files

- `mkl_pblas.h`

Description

The functions `p?asum` compute the sum of the magnitudes of elements of a distributed vector `sub(x)`, where `sub(x)` denotes $X(ix, jx:jx+n-1)$ if `incx=m_x`, and $X(ix:ix+n-1, jx)$ if `incx=1`.

Input Parameters

<code>n</code>	(global) The length of distributed vector <code>sub(x)</code> , $n \geq 0$.
<code>x</code>	(local) Array, size $(jx-1)*m_x + ix + (n-1)*abs(incx)$. This array contains the entries of the distributed vector <code>sub(x)</code> .
<code>ix, jx</code>	(global) The row and column indices in the distributed matrix X indicating the first row and the first column of the submatrix <code>sub(X)</code> , respectively.
<code>descx</code>	(global and local) array of dimension 9. The array descriptor of the distributed matrix X .
<code>incx</code>	(global) Specifies the increment for the elements of <code>sub(x)</code> . Only two values are supported, namely 1 and <code>m_x</code> . <code>incx</code> must not be zero.

Output Parameters

<code>asum</code>	(local) and <code>p?casum</code> . Contains the sum of magnitudes of elements of the distributed vector only in its scope.

p?axpy

Computes a distributed vector-scalar product and adds the result to a distributed vector.

Syntax

```
void psaxpy (MKL_INT *n , float *a , float *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx , float *y , MKL_INT *iy , MKL_INT *jy , MKL_INT *descy ,
MKL_INT *incy );
```

```
void pdaxpy (MKL_INT *n , double *a , double *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx , double *y , MKL_INT *iy , MKL_INT *jy , MKL_INT *descy ,
MKL_INT *incy );
```

```
void pcaxpy (MKL_INT *n , float *a , float *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx , float *y , MKL_INT *iy , MKL_INT *jy , MKL_INT *descy ,
MKL_INT *incy );
```

```
void pzaxpy (MKL_INT *n , double *a , double *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx , double *y , MKL_INT *iy , MKL_INT *jy , MKL_INT *descy ,
MKL_INT *incy );
```

Include Files

- `mk1_pblas.h`

Description

The `p?axpy` routines perform the following operation with distributed vectors:

```
sub(y) := sub(y) + a*sub(x)
```

where:

a is a scalar;

`sub(x)` and `sub(y)` are n -element distributed vectors.

`sub(x)` denotes $X(ix, jx:jx+n-1)$ if $incx=m_x$, and $X(ix: ix+n-1, jx)$ if $incx= 1$;

`sub(y)` denotes $Y(iy, jy:jy+n-1)$ if $incy=m_y$, and $Y(iy: iy+n-1, jy)$ if $incy= 1$.

Input Parameters

n	(global) The length of distributed vectors, $n \geq 0$.
a	(local) Specifies the scalar a .
x	(local) Array, size $(jx-1)*m_x + ix+(n-1)*abs(incx)$. This array contains the entries of the distributed vector <code>sub(x)</code> .
ix, jx	(global) The row and column indices in the distributed matrix X indicating the first row and the first column of the submatrix <code>sub(X)</code> , respectively.
$descx$	(global and local) array of dimension 9. The array descriptor of the distributed matrix X .
$incx$	(global) Specifies the increment for the elements of <code>sub(x)</code> . Only two values are supported, namely 1 and m_x . $incx$ must not be zero.
y	(local) Array, size $(jy-1)*m_y + iy+(n-1)*abs(incy)$. This array contains the entries of the distributed vector <code>sub(y)</code> .
iy, jy	(global) The row and column indices in the distributed matrix Y indicating the first row and the first column of the submatrix <code>sub(Y)</code> , respectively.
$descy$	(global and local) array of dimension 9. The array descriptor of the distributed matrix Y .
$incy$	(global) Specifies the increment for the elements of <code>sub(y)</code> . Only two values are supported, namely 1 and m_y . $incy$ must not be zero.

Output Parameters

y	Overwritten by <code>sub(y) := sub(y) + a*sub(x)</code> .

p?copy

Copies one distributed vector to another vector.

Syntax

```
void pscopy (MKL_INT *n , float *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx ,
MKL_INT *incx , float *y , MKL_INT *iy , MKL_INT *jy , MKL_INT *descy , MKL_INT
*incy );
```

```
void pdcopy (MKL_INT *n , double *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx ,
MKL_INT *incx , double *y , MKL_INT *iy , MKL_INT *jy , MKL_INT *descy , MKL_INT
*incy );
```

```
void pccopy (MKL_INT *n , float *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx ,
MKL_INT *incx , float *y , MKL_INT *iy , MKL_INT *jy , MKL_INT *descy , MKL_INT
*incy );
```

```
void pzcopy (MKL_INT *n , double *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx ,
MKL_INT *incx , double *y , MKL_INT *iy , MKL_INT *jy , MKL_INT *descy , MKL_INT
*incy );
```

```
void picopy (MKL_INT *n , MKL_INT *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx ,
MKL_INT *incx , MKL_INT *y , MKL_INT *iy , MKL_INT *jy , MKL_INT *descy , MKL_INT
*incy );
```

Include Files

- mkl_pblas.h

Description

The p?copy routines perform a copy operation with distributed vectors defined as

```
sub(y) = sub(x),
```

where $\text{sub}(x)$ and $\text{sub}(y)$ are n -element distributed vectors.

$\text{sub}(x)$ denotes $X(ix, jx:jx+n-1)$ if $incx=m_x$, and $X(ix: ix+n-1, jx)$ if $incx= 1$;

$\text{sub}(y)$ denotes $Y(iy, jy:jy+n-1)$ if $incy=m_y$, and $Y(iy: iy+n-1, jy)$ if $incy= 1$.

Input Parameters

n	(global) The length of distributed vectors, $n \geq 0$.
x	(local) Array, size $(jx-1)*m_x + ix+(n-1)*abs(incx)$. This array contains the entries of the distributed vector $\text{sub}(x)$.
ix, jx	(global) The row and column indices in the distributed matrix X indicating the first row and the first column of the submatrix $\text{sub}(X)$, respectively.
$descx$	(global and local) array of dimension 9. The array descriptor of the distributed matrix X .
$incx$	(global) Specifies the increment for the elements of $\text{sub}(x)$. Only two values are supported, namely 1 and m_x . $incx$ must not be zero.
y	(local)

Array, size $(jy-1)*m_y + iy+(n-1)*abs(incy)$.

This array contains the entries of the distributed vector $sub(y)$.

iy, jy (global) The row and column indices in the distributed matrix Y indicating the first row and the first column of the submatrix $sub(Y)$, respectively.

descy (global and local) array of dimension 9. The array descriptor of the distributed matrix Y .

incy (global) Specifies the increment for the elements of $sub(y)$. Only two values are supported, namely 1 and m_y . *incy* must not be zero.

Output Parameters

y Overwritten with the distributed vector $sub(x)$.

p?dot

Computes the dot product of two distributed real vectors.

Syntax

```
void psdot (MKL_INT *n , float *dot , float *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx , float *y , MKL_INT *iy , MKL_INT *jy , MKL_INT *descy ,
MKL_INT *incy );
```

```
void pddot (MKL_INT *n , double *dot , double *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx , double *y , MKL_INT *iy , MKL_INT *jy , MKL_INT *descy ,
MKL_INT *incy );
```

Include Files

- mkl_pblas.h

Description

The ?dot functions compute the dot product *dot* of two distributed real vectors defined as

```
dot = sub(x)'*sub(y)
```

where $sub(x)$ and $sub(y)$ are n -element distributed vectors.

$sub(x)$ denotes $X(ix, jx:jx+n-1)$ if $incx=m_x$, and $X(ix: ix+n-1, jx)$ if $incx= 1$;

$sub(y)$ denotes $Y(iy, jy:jy+n-1)$ if $incy=m_y$, and $Y(iy: iy+n-1, jy)$ if $incy= 1$.

Input Parameters

n (global) The length of distributed vectors, $n \geq 0$.

x (local)

Array, size $(jx-1)*m_x + ix+(n-1)*abs(incx)$.

This array contains the entries of the distributed vector $sub(x)$.

ix, jx (global) The row and column indices in the distributed matrix X indicating the first row and the first column of the submatrix $sub(X)$, respectively.

<i>descx</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>X</i> .
<i>incx</i>	(global) Specifies the increment for the elements of <i>sub(x)</i> . Only two values are supported, namely 1 and <i>m_x</i> . <i>incx</i> must not be zero.
<i>y</i>	(local) Array, size $(jy-1)*m_y + iy + (n-1)*abs(incy)$. This array contains the entries of the distributed vector <i>sub(y)</i> .
<i>iy, jy</i>	(global) The row and column indices in the distributed matrix <i>Y</i> indicating the first row and the first column of the submatrix <i>sub(Y)</i> , respectively.
<i>descy</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>Y</i> .
<i>incy</i>	(global) Specifies the increment for the elements of <i>sub(y)</i> . Only two values are supported, namely 1 and <i>m_y</i> . <i>incy</i> must not be zero.

Output Parameters

<i>dot</i>	(local) Dot product of <i>sub(x)</i> and <i>sub(y)</i> only in their scope.

p?dotc

Computes the dot product of two distributed complex vectors, one of them is conjugated.

Syntax

```
void pcdotc (MKL_INT *n , float *dotc , float *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx , MKL_INT *incx , float *y , MKL_INT *iy , MKL_INT *jy , MKL_INT *descy , MKL_INT *incy );
```

```
void pzdotc (MKL_INT *n , double *dotc , double *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx , MKL_INT *incx , double *y , MKL_INT *iy , MKL_INT *jy , MKL_INT *descy , MKL_INT *incy );
```

Include Files

- `mkl_pblas.h`

Description

The `p?dotc` functions compute the dot product *dotc* of two distributed vectors, with one vector conjugated:

```
dotc = conjg(sub(x)')*sub(y)
```

where *sub(x)* and *sub(y)* are *n*-element distributed vectors.

sub(x) denotes *X(ix, jx:jx+n-1)* if *incx=m_x*, and *X(ix: ix+n-1, jx)* if *incx= 1*;

sub(y) denotes *Y(iy, jy:jy+n-1)* if *incy=m_y*, and *Y(iy: iy+n-1, jy)* if *incy= 1*.

Input Parameters

<i>n</i>	(global) The length of distributed vectors, $n \geq 0$.
<i>x</i>	(local) Array, size $(j_x-1)*m_x + ix + (n-1)*abs(incx)$. This array contains the entries of the distributed vector $sub(x)$.
<i>ix, jx</i>	(global) The row and column indices in the distributed matrix <i>X</i> indicating the first row and the first column of the submatrix $sub(X)$, respectively.
<i>descx</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>X</i> .
<i>incx</i>	(global) Specifies the increment for the elements of $sub(x)$. Only two values are supported, namely 1 and m_x . <i>incx</i> must not be zero.
<i>y</i>	(local) Array, size $(j_y-1)*m_y + iy + (n-1)*abs(incy)$. This array contains the entries of the distributed vector $sub(y)$.
<i>iy, jy</i>	(global) The row and column indices in the distributed matrix <i>Y</i> indicating the first row and the first column of the submatrix $sub(Y)$, respectively.
<i>descy</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>Y</i> .
<i>incy</i>	(global) Specifies the increment for the elements of $sub(y)$. Only two values are supported, namely 1 and m_y . <i>incy</i> must not be zero.

Output Parameters

<i>dotc</i>	(local) Dot product of $sub(x)$ and $sub(y)$ only in their scope.

p?dotu

Computes the dot product of two distributed complex vectors.

Syntax

```
void pcdotu (MKL_INT *n , float *dotu , float *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx , float *y , MKL_INT *iy , MKL_INT *jy , MKL_INT *descy ,
MKL_INT *incy );

void pzdotu (MKL_INT *n , double *dotu , double *x , MKL_INT *ix , MKL_INT *jx ,
MKL_INT *descx , MKL_INT *incx , double *y , MKL_INT *iy , MKL_INT *jy , MKL_INT
*descy , MKL_INT *incy );
```

Include Files

- mkl_pblas.h

Description

The `p?dotu` functions compute the dot product *dotu* of two distributed vectors defined as

```
dotu = sub(x)'*sub(y)
```

where `sub(x)` and `sub(y)` are n -element distributed vectors.

`sub(x)` denotes $X(ix, jx:jx+n-1)$ if $incx=m\_x$, and $X(ix: ix+n-1, jx)$ if $incx= 1$;

`sub(y)` denotes $Y(iy, jy:jy+n-1)$ if $incy=m\_y$, and $Y(iy: iy+n-1, jy)$ if $incy= 1$.

Input Parameters

<code>n</code>	(global) The length of distributed vectors, $n \geq 0$.
<code>x</code>	(local) Array, size $(jx-1)*m\_x + ix+(n-1)*abs(incx)$. This array contains the entries of the distributed vector <code>sub(x)</code> .
<code>ix, jx</code>	(global) The row and column indices in the distributed matrix X indicating the first row and the first column of the submatrix <code>sub(X)</code> , respectively.
<code>descx</code>	(global and local) array of dimension 9. The array descriptor of the distributed matrix X .
<code>incx</code>	(global) Specifies the increment for the elements of <code>sub(x)</code> . Only two values are supported, namely 1 and m_x . <code>incx</code> must not be zero.
<code>y</code>	(local) Array, size $(jy-1)*m\_y + iy+(n-1)*abs(incy)$. This array contains the entries of the distributed vector <code>sub(y)</code> .
<code>iy, jy</code>	(global) The row and column indices in the distributed matrix Y indicating the first row and the first column of the submatrix <code>sub(Y)</code> , respectively.
<code>descy</code>	(global and local) array of dimension 9. The array descriptor of the distributed matrix Y .
<code>incy</code>	(global) Specifies the increment for the elements of <code>sub(y)</code> . Only two values are supported, namely 1 and m_y . <code>incy</code> must not be zero.

Output Parameters

<code>dotu</code>	(local) Dot product of <code>sub(x)</code> and <code>sub(y)</code> only in their scope.

p?nrm2

Computes the Euclidean norm of a distributed vector.

Syntax

```
void psnrm2 (MKL_INT *n , float *norm2 , float *x , MKL_INT *ix , MKL_INT *jx ,
MKL_INT *descx , MKL_INT *incx );
```

```

void pdnrm2 (MKL_INT *n , double *norm2 , double *x , MKL_INT *ix , MKL_INT *jx ,
MKL_INT *descx , MKL_INT *incx );

void pscnrm2 (MKL_INT *n , float *norm2 , float *x , MKL_INT *ix , MKL_INT *jx ,
MKL_INT *descx , MKL_INT *incx );

void pdznrm2 (MKL_INT *n , double *norm2 , double *x , MKL_INT *ix , MKL_INT *jx ,
MKL_INT *descx , MKL_INT *incx );

```

Include Files

- mkl_pblas.h

Description

The `p?nrm2` functions compute the Euclidean norm of a distributed vector `sub(x)`, where `sub(x)` is an n -element distributed vector.

`sub(x)` denotes $X(ix, jx:jx+n-1)$ if `incx=mx`, and $X(ix: ix+n-1, jx)$ if `incx= 1`.

Input Parameters

<code>n</code>	(global) The length of distributed vector <code>sub(x)</code> , $n \geq 0$.
<code>x</code>	(local) Array, size $(jx-1)*m_x + ix+(n-1)*abs(incx)$. This array contains the entries of the distributed vector <code>sub(x)</code> .
<code>ix, jx</code>	(global) The row and column indices in the distributed matrix X indicating the first row and the first column of the submatrix <code>sub(X)</code> , respectively.
<code>descx</code>	(global and local) array of dimension 9. The array descriptor of the distributed matrix X .
<code>incx</code>	(global) Specifies the increment for the elements of <code>sub(x)</code> . Only two values are supported, namely 1 and m_x . <code>incx</code> must not be zero.

Output Parameters

<code>norm2</code>	(local) and <code>pscnrm2</code> . Contains the Euclidean norm of a distributed vector only in its scope.

p?scal

Computes a product of a distributed vector by a scalar.

Syntax

```

void psscal (MKL_INT *n , float *a , float *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx );

void pdscal (MKL_INT *n , double *a , double *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx );

void pcscal (MKL_INT *n , float *a , float *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx );

```

```
void pzscal (MKL_INT *n , double *a , double *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx );

void pcscal (MKL_INT *n , float *a , float *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx );

void pzdscal (MKL_INT *n , double *a , double *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx );
```

Include Files

- mkl_pblas.h

Description

The `p?scal` routines multiplies a n -element distributed vector `sub(x)` by the scalar a :

`sub(x) = a*sub(x),`

where `sub(x)` denotes $X(ix, jx:jx+n-1)$ if `incx=mx`, and $X(ix: ix+n-1, jx)$ if `incx= 1`.

Input Parameters

n	(global) The length of distributed vector <code>sub(x)</code> , $n \geq 0$.
a	(global) and <code>pcscal</code> Specifies the scalar a .
x	(local) Array, size $(jx-1)*m_x + ix+(n-1)*abs(incx)$. This array contains the entries of the distributed vector <code>sub(x)</code> .
ix, jx	(global) The row and column indices in the distributed matrix X indicating the first row and the first column of the submatrix <code>sub(X)</code> , respectively.
$descx$	(global and local) array of dimension 9. The array descriptor of the distributed matrix X .
$incx$	(global) Specifies the increment for the elements of <code>sub(x)</code> . Only two values are supported, namely 1 and m_x . <code>incx</code> must not be zero.

Output Parameters

x	Overwritten by the updated distributed vector <code>sub(x)</code>

p?swap

Swaps two distributed vectors.

Syntax

```
void psswap (MKL_INT *n , float *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx ,
MKL_INT *incx , float *y , MKL_INT *iy , MKL_INT *jy , MKL_INT *descy , MKL_INT
*incy );

void pdswap (MKL_INT *n , double *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx ,
MKL_INT *incx , double *y , MKL_INT *iy , MKL_INT *jy , MKL_INT *descy , MKL_INT
*incy );
```

```

void pswap (MKL_INT *n , float *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx ,
MKL_INT *incx , float *y , MKL_INT *iy , MKL_INT *jy , MKL_INT *descy , MKL_INT
*incy );

void pzswap (MKL_INT *n , double *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx ,
MKL_INT *incx , double *y , MKL_INT *iy , MKL_INT *jy , MKL_INT *descy , MKL_INT
*incy );

```

Include Files

- mkl_pblas.h

Description

Given two distributed vectors $\text{sub}(x)$ and $\text{sub}(y)$, the `p?swap` routines return vectors $\text{sub}(y)$ and $\text{sub}(x)$ swapped, each replacing the other.

Here $\text{sub}(x)$ denotes $X(ix, jx:jx+n-1)$ if $incx=m_x$, and $X(ix: ix+n-1, jx)$ if $incx= 1$;

$\text{sub}(y)$ denotes $Y(iy, jy:jy+n-1)$ if $incy=m_y$, and $Y(iy: iy+n-1, jy)$ if $incy= 1$.

Input Parameters

n	(global) The length of distributed vectors, $n \geq 0$.
x	(local) Array, size $(jx-1)*m_x + ix+(n-1)*abs(incx)$. This array contains the entries of the distributed vector $\text{sub}(x)$.
ix, jx	(global) The row and column indices in the distributed matrix X indicating the first row and the first column of the submatrix $\text{sub}(X)$, respectively.
$descx$	(global and local) array of dimension 9. The array descriptor of the distributed matrix X .
$incx$	(global) Specifies the increment for the elements of $\text{sub}(x)$. Only two values are supported, namely 1 and m_x . $incx$ must not be zero.
y	(local) Array, size $(jy-1)*m_y + iy+(n-1)*abs(incy)$. This array contains the entries of the distributed vector $\text{sub}(y)$.
iy, jy	(global) The row and column indices in the distributed matrix Y indicating the first row and the first column of the submatrix $\text{sub}(Y)$, respectively.
$descy$	(global and local) array of dimension 9. The array descriptor of the distributed matrix Y .
$incy$	(global) Specifies the increment for the elements of $\text{sub}(y)$. Only two values are supported, namely 1 and m_y . $incy$ must not be zero.

Output Parameters

x	Overwritten by distributed vector $\text{sub}(y)$.
y	Overwritten by distributed vector $\text{sub}(x)$.

PBLAS Level 2 Routines

This section describes PBLAS Level 2 routines, which perform distributed matrix-vector operations. [Table "PBLAS Level 2 Routine Groups and Their Data Types"](#) lists the PBLAS Level 2 routine groups and the data types associated with them.

PBLAS Level 2 Routine Groups and Their Data Types

Routine Groups	Data Types	Description
p?gemv	s, d, c, z	Matrix-vector product using a distributed general matrix
p?agemv	s, d, c, z	Matrix-vector product using absolute values for a distributed general matrix
p?ger	s, d	Rank-1 update of a distributed general matrix
p?gerc	c, z	Rank-1 update (conjugated) of a distributed general matrix
p?geru	c, z	Rank-1 update (unconjugated) of a distributed general matrix
p?hemv	c, z	Matrix-vector product using a distributed Hermitian matrix
p?ahemv	c, z	Matrix-vector product using absolute values for a distributed Hermitian matrix
p?her	c, z	Rank-1 update of a distributed Hermitian matrix
p?her2	c, z	Rank-2 update of a distributed Hermitian matrix
p?symv	s, d	Matrix-vector product using a distributed symmetric matrix
p?asymv	s, d	Matrix-vector product using absolute values for a distributed symmetric matrix
p?syr	s, d	Rank-1 update of a distributed symmetric matrix
p?syr2	s, d	Rank-2 update of a distributed symmetric matrix
p?trmv	s, d, c, z	Distributed matrix-vector product using a triangular matrix
p?atrmv	s, d, c, z	Distributed matrix-vector product using absolute values for a triangular matrix
p?trsv	s, d, c, z	Solves a system of linear equations whose coefficients are in a distributed triangular matrix

[p?gemv](#)

Computes a distributed matrix-vector product using a general matrix.

Syntax

```
void psgemv (char *trans , MKL_INT *m , MKL_INT *n , float *alpha , float *a , MKL_INT
*ia , MKL_INT *ja , MKL_INT *desca , float *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx , float *beta , float *y , MKL_INT *iy , MKL_INT *jy , MKL_INT
*descy , MKL_INT *incy );
```

```

void pdgemv (char *trans , MKL_INT *m , MKL_INT *n , double *alpha , double *a ,
MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *x , MKL_INT *ix , MKL_INT *jx ,
MKL_INT *descx , MKL_INT *incx , double *beta , double *y , MKL_INT *iy , MKL_INT
*jy , MKL_INT *descy , MKL_INT *incy );

void pcgemv (char *trans , MKL_INT *m , MKL_INT *n , float *alpha , float *a , MKL_INT
*ia , MKL_INT *ja , MKL_INT *desca , float *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx , float *beta , float *y , MKL_INT *iy , MKL_INT *jy , MKL_INT
*descy , MKL_INT *incy );

void pzgemv (char *trans , MKL_INT *m , MKL_INT *n , double *alpha , double *a ,
MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *x , MKL_INT *ix , MKL_INT *jx ,
MKL_INT *descx , MKL_INT *incx , double *beta , double *y , MKL_INT *iy , MKL_INT
*jy , MKL_INT *descy , MKL_INT *incy );

```

Include Files

- mkl_pblas.h

Description

The p?gemv routines perform a distributed matrix-vector operation defined as

```
sub(y) := alpha*sub(A)*sub(x) + beta*sub(y),
```

or

```
sub(y) := alpha*sub(A)'*sub(x) + beta*sub(y),
```

or

```
sub(y) := alpha*conjg(sub(A)')*sub(x) + beta*sub(y),
```

where

alpha and *beta* are scalars,

sub(A) is a *m*-by-*n* submatrix, sub(A) = A(ia:ia+m-1, ja:ja+n-1),

sub(x) and sub(y) are subvectors.

When *trans* = 'N' or 'n', sub(x) denotes X(ix, jx:jx+n-1) if *incx* = *m_x*, and X(ix: ix+n-1, jx) if *incx* = 1, sub(y) denotes Y(iy, jy:jy+m-1) if *incy* = *m_y*, and Y(iy: iy+m-1, jy) if *incy* = 1.

When *trans* = 'T' or 't', or 'C', or 'c', sub(x) denotes X(ix, jx:jx+m-1) if *incx* = *m_x*, and X(ix: ix+m-1, jx) if *incx* = 1, sub(y) denotes Y(iy, jy:jy+n-1) if *incy* = *m_y*, and Y(iy: iy+m-1, jy) if *incy* = 1.

Input Parameters

<i>trans</i>	(global) Specifies the operation: if <i>trans</i> = 'N' or 'n', then sub(y) := alpha*sub(A)*sub(x) + beta*sub(y); if <i>trans</i> = 'T' or 't', then sub(y) := alpha*sub(A)'*sub(x) + beta*sub(y); if <i>trans</i> = 'C' or 'c', then sub(y) := alpha*conjg(sub(A)')*sub(x) + beta*sub(y).
<i>m</i>	(global) Specifies the number of rows of the distributed matrix sub(A), $m \geq 0$.

<i>n</i>	(global) Specifies the number of columns of the distributed matrix $\text{sub}(A)$, $n \geq 0$.
<i>alpha</i>	(global) Specifies the scalar <i>alpha</i> .
<i>a</i>	(local) Array, size $(lld\_a, LOCq(ja+n-1))$. Before entry this array must contain the local pieces of the distributed matrix $\text{sub}(A)$.
<i>ia, ja</i>	(global) The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .
<i>x</i>	(local) Array, size $(jx-1)*m\_x + ix+(n-1)*abs(incx)$ when <i>trans</i> = 'N' or 'n', and $(jx-1)*m\_x + ix+(m-1)*abs(incx)$ otherwise. This array contains the entries of the distributed vector $\text{sub}(x)$.
<i>ix, jx</i>	(global) The row and column indices in the distributed matrix <i>X</i> indicating the first row and the first column of the submatrix $\text{sub}(x)$, respectively.
<i>descx</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>X</i> .
<i>incx</i>	(global) Specifies the increment for the elements of $\text{sub}(x)$. Only two values are supported, namely 1 and m_x . <i>incx</i> must not be zero.
<i>beta</i>	(global) Specifies the scalar <i>beta</i> . When <i>beta</i> is set to zero, then $\text{sub}(y)$ need not be set on input.
<i>y</i>	(local) Array, size $(jy-1)*m\_y + iy+(m-1)*abs(incy)$ when <i>trans</i> = 'N' or 'n', and $(jy-1)*m\_y + iy+(n-1)*abs(incy)$ otherwise. This array contains the entries of the distributed vector $\text{sub}(y)$.
<i>iy, jy</i>	(global) The row and column indices in the distributed matrix <i>Y</i> indicating the first row and the first column of the submatrix $\text{sub}(y)$, respectively.
<i>descy</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>Y</i> .
<i>incy</i>	(global) Specifies the increment for the elements of $\text{sub}(y)$. Only two values are supported, namely 1 and m_y . <i>incy</i> must not be zero.

Output Parameters

<i>y</i>	Overwritten by the updated distributed vector $\text{sub}(y)$.

p?agemv

Computes a distributed matrix-vector product using absolute values for a general matrix.

Syntax

```
void psagemv (char *trans , MKL_INT *m , MKL_INT *n , float *alpha , float *a ,
MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *x , MKL_INT *ix , MKL_INT *jx ,
MKL_INT *descx , MKL_INT *incx , float *beta , float *y , MKL_INT *iy , MKL_INT *jy ,
MKL_INT *descy , MKL_INT *incy );

void pdagemv (char *trans , MKL_INT *m , MKL_INT *n , double *alpha , double *a ,
MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *x , MKL_INT *ix , MKL_INT *jx ,
MKL_INT *descx , MKL_INT *incx , double *beta , double *y , MKL_INT *iy , MKL_INT
*jy , MKL_INT *descy , MKL_INT *incy );

void pcagemv (char *trans , MKL_INT *m , MKL_INT *n , float *alpha , float *a ,
MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *x , MKL_INT *ix , MKL_INT *jx ,
MKL_INT *descx , MKL_INT *incx , float *beta , float *y , MKL_INT *iy , MKL_INT *jy ,
MKL_INT *descy , MKL_INT *incy );

void pzagemv (char *trans , MKL_INT *m , MKL_INT *n , double *alpha , double *a ,
MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *x , MKL_INT *ix , MKL_INT *jx ,
MKL_INT *descx , MKL_INT *incx , double *beta , double *y , MKL_INT *iy , MKL_INT
*jy , MKL_INT *descy , MKL_INT *incy );
```

Include Files

- mkl_pblas.h

Description

The p?agemv routines perform a distributed matrix-vector operation defined as

```
sub(y) := abs(alpha)*abs(sub(A'))*abs(sub(x)) + abs(beta*sub(y)),
```

or

```
sub(y) := abs(alpha)*abs(sub(A'))*abs(sub(x)) + abs(beta*sub(y)),
```

or

```
sub(y) := abs(alpha)*abs(conjg(sub(A')))*abs(sub(x)) + abs(beta*sub(y)),
```

where

alpha and *beta* are scalars,

sub(A) is a *m*-by-*n* submatrix, sub(A) = A(ia:ia+m-1, ja:ja+n-1),

sub(x) and sub(y) are subvectors.

When *trans* = 'N' or 'n',

sub(x) denotes X(ix:ix, jx:jx+n-1) if incx = m_x, and

X(ix:ix+n-1, jx:jx) if incx = 1,

sub(y) denotes Y(iy:iy, jy:jy+m-1) if incy = m_y, and

Y(iy:iy+m-1, jy:jy) if incy = 1.

When *trans* = 'T' or 't', or 'C', or 'c',

sub(x) denotes X(ix:ix, jx:jx+m-1) if incx = m_x, and

$X(ix:ix+m-1, jx:jx)$ if $incx = 1$,
 $sub(y)$ denotes $Y(iy:iy, jy:jy+n-1)$ if $incy = m_y$, and
 $Y(iy:iy+m-1, jy:jy)$ if $incy = 1$.

Input Parameters

<i>trans</i>	(global) Specifies the operation: if <i>trans</i> = 'N' or 'n', then $sub(y) := alpha * sub(A) * sub(x) + beta * sub(y) $ if <i>trans</i> = 'T' or 't', then $sub(y) := alpha * sub(A)' * sub(x) + beta * sub(y) $ if <i>trans</i> = 'C' or 'c', then $sub(y) := alpha * sub(A)' * sub(x) + beta * sub(y) $.
<i>m</i>	(global) Specifies the number of rows of the distributed matrix $sub(A)$, $m \geq 0$.
<i>n</i>	(global) Specifies the number of columns of the distributed matrix $sub(A)$, $n \geq 0$.
<i>alpha</i>	(global) Specifies the scalar <i>alpha</i> .
<i>a</i>	(local) Array, size $(lld\_a, LOCq(ja+n-1))$. Before entry this array must contain the local pieces of the distributed matrix $sub(A)$.
<i>ia, ja</i>	(global) The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix $sub(A)$, respectively.
<i>desca</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .
<i>x</i>	(local) Array, size $(jx-1)*m_x + ix+(n-1)*abs(incx)$ when <i>trans</i> = 'N' or 'n', and $(jx-1)*m_x + ix+(m-1)*abs(incx)$ otherwise. This array contains the entries of the distributed vector $sub(x)$.
<i>ix, jx</i>	(global) The row and column indices in the distributed matrix <i>X</i> indicating the first row and the first column of the submatrix $sub(x)$, respectively.
<i>descx</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>X</i> .
<i>incx</i>	(global) Specifies the increment for the elements of $sub(x)$. Only two values are supported, namely 1 and m_x . <i>incx</i> must not be zero.
<i>beta</i>	(global) Specifies the scalar <i>beta</i> . When <i>beta</i> is set to zero, then $sub(y)$ need not be set on input.

<i>y</i>	(local) Array, size $(jy-1)*m_y + iy+(m-1)*abs(incy)$ when <i>trans</i> = 'N' or 'n', and $(jy-1)*m_y + iy+(n-1)*abs(incy)$ otherwise. This array contains the entries of the distributed vector <code>sub(y)</code> .
<i>iy, jy</i>	(global) The row and column indices in the distributed matrix <i>Y</i> indicating the first row and the first column of the submatrix <code>sub(y)</code> , respectively.
<i>descy</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>Y</i> .
<i>incy</i>	(global) Specifies the increment for the elements of <code>sub(y)</code> . Only two values are supported, namely 1 and m_y . <i>incy</i> must not be zero.

Output Parameters

<i>y</i>	Overwritten by the updated distributed vector <code>sub(y)</code> .

p?ger

Performs a rank-1 update of a distributed general matrix.

Syntax

```
void psger (MKL_INT *m , MKL_INT *n , float *alpha , float *x , MKL_INT *ix , MKL_INT
*jx , MKL_INT *descx , MKL_INT *incx , float *y , MKL_INT *iy , MKL_INT *jy , MKL_INT
*descy , MKL_INT *incy , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );

void pdger (MKL_INT *m , MKL_INT *n , double *alpha , double *x , MKL_INT *ix ,
MKL_INT *jx , MKL_INT *descx , MKL_INT *incx , double *y , MKL_INT *iy , MKL_INT *jy ,
MKL_INT *descy , MKL_INT *incy , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca );
```

Include Files

- `mkl_pblas.h`

Description

The `p?ger` routines perform a distributed matrix-vector operation defined as

$$\text{sub}(A) := \alpha \text{sub}(x) \text{sub}(y)^T + \text{sub}(A),$$

where:

alpha is a scalar,

`sub(A)` is a *m*-by-*n* distributed general matrix, `sub(A)=A(ia:ia+m-1, ja:ja+n-1)`,

`sub(x)` is an *m*-element distributed vector, `sub(y)` is an *n*-element distributed vector,

`sub(x)` denotes $X(ix, jx:jx+m-1)$ if *incx* = m_x , and $X(ix: ix+m-1, jx)$ if *incx* = 1,

`sub(y)` denotes $Y(iy, jy:jy+n-1)$ if *incy* = m_y , and $Y(iy: iy+n-1, jy)$ if *incy* = 1.

Input Parameters

<i>m</i>	(global) Specifies the number of rows of the distributed matrix $\text{sub}(A)$, $m \geq 0$.
<i>n</i>	(global) Specifies the number of columns of the distributed matrix $\text{sub}(A)$, $n \geq 0$.
<i>alpha</i>	(global) Specifies the scalar <i>alpha</i> .
<i>x</i>	(local) Array, size at least $(j_x-1)*m_x + ix + (m-1)*\text{abs}(incx)$. This array contains the entries of the distributed vector $\text{sub}(x)$.
<i>ix, jx</i>	(global) The row and column indices in the distributed matrix <i>X</i> indicating the first row and the first column of the submatrix $\text{sub}(x)$, respectively.
<i>descx</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>X</i> .
<i>incx</i>	(global) Specifies the increment for the elements of $\text{sub}(x)$. Only two values are supported, namely 1 and m_x . <i>incx</i> must not be zero.
<i>y</i>	(local) Array, size at least $(j_y-1)*m_y + iy + (n-1)*\text{abs}(incy)$. This array contains the entries of the distributed vector $\text{sub}(y)$.
<i>iy, jy</i>	(global) The row and column indices in the distributed matrix <i>Y</i> indicating the first row and the first column of the submatrix $\text{sub}(y)$, respectively.
<i>descy</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>Y</i> .
<i>incy</i>	(global) Specifies the increment for the elements of $\text{sub}(y)$. Only two values are supported, namely 1 and m_y . <i>incy</i> must not be zero.
<i>a</i>	(local) Array, size $(lld_a, LOCq(ja+n-1))$. Before entry this array contains the local pieces of the distributed matrix $\text{sub}(A)$.
<i>ia, ja</i>	(global) The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .

Output Parameters

<i>a</i>	Overwritten by the updated distributed matrix $\text{sub}(A)$.

p?gerc

Performs a rank-1 update (conjugated) of a distributed general matrix.

Syntax

```
void pcgerc (MKL_INT *m , MKL_INT *n , float *alpha , float *x , MKL_INT *ix , MKL_INT
*jx , MKL_INT *descx , MKL_INT *incx , float *y , MKL_INT *iy , MKL_INT *jy , MKL_INT
*descy , MKL_INT *incy , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );

void pzgerc (MKL_INT *m , MKL_INT *n , double *alpha , double *x , MKL_INT *ix ,
MKL_INT *jx , MKL_INT *descx , MKL_INT *incx , double *y , MKL_INT *iy , MKL_INT *jy ,
MKL_INT *descy , MKL_INT *incy , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca );
```

Include Files

- mkl_pblas.h

Description

The p?gerc routines perform a distributed matrix-vector operation defined as

$$\text{sub}(A) := \alpha \text{sub}(x) \text{conjg}(\text{sub}(y)^T) + \text{sub}(A),$$

where:

α is a scalar,

$\text{sub}(A)$ is a m -by- n distributed general matrix, $\text{sub}(A) = A(ia:ia+m-1, ja:ja+n-1)$,

$\text{sub}(x)$ is an m -element distributed vector, $\text{sub}(y)$ is an n -element distributed vector,

$\text{sub}(x)$ denotes $X(ix, jx:jx+m-1)$ if $incx = m_x$, and $X(ix:ix+m-1, jx)$ if $incx = 1$,

$\text{sub}(y)$ denotes $Y(iy, jy:jy+n-1)$ if $incy = m_y$, and $Y(iy:iy+n-1, jy)$ if $incy = 1$.

Input Parameters

m	(global) Specifies the number of rows of the distributed matrix $\text{sub}(A)$, $m \geq 0$.
n	(global) Specifies the number of columns of the distributed matrix $\text{sub}(A)$, $n \geq 0$.
α	(global) Specifies the scalar α .
x	(local) Array, size at least $(jx-1)*m_x + ix + (n-1)*\text{abs}(incx)$. This array contains the entries of the distributed vector $\text{sub}(x)$.
ix, jx	(global) The row and column indices in the distributed matrix X indicating the first row and the first column of the submatrix $\text{sub}(x)$, respectively.
$descx$	(global and local) array of dimension 9. The array descriptor of the distributed matrix X .

<i>incx</i>	(global) Specifies the increment for the elements of $\text{sub}(x)$. Only two values are supported, namely 1 and m_x . <i>incx</i> must not be zero.
<i>y</i>	(local) Array, size at least $(jy-1)*m_y + iy + (n-1)*\text{abs}(incy)$. This array contains the entries of the distributed vector $\text{sub}(y)$.
<i>iy, jy</i>	(global) The row and column indices in the distributed matrix <i>Y</i> indicating the first row and the first column of the submatrix $\text{sub}(y)$, respectively.
<i>descy</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>Y</i> .
<i>incy</i>	(global) Specifies the increment for the elements of $\text{sub}(y)$. Only two values are supported, namely 1 and m_y . <i>incy</i> must not be zero.
<i>a</i>	(local) Array, size at least $(lld_a, \text{LOCq}(ja+n-1))$. Before entry this array contains the local pieces of the distributed matrix $\text{sub}(A)$.
<i>ia, ja</i>	(global) The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .

Output Parameters

<i>a</i>	Overwritten by the updated distributed matrix $\text{sub}(A)$.

p?geru

Performs a rank-1 update (unconjugated) of a distributed general matrix.

Syntax

```
void pcgeru (MKL_INT *m , MKL_INT *n , float *alpha , float *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx , MKL_INT *incx , float *y , MKL_INT *iy , MKL_INT *jy , MKL_INT *descy , MKL_INT *incy , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );

void pzgeru (MKL_INT *m , MKL_INT *n , double *alpha , double *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx , MKL_INT *incx , double *y , MKL_INT *iy , MKL_INT *jy , MKL_INT *descy , MKL_INT *incy , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );
```

Include Files

- mkl_pblas.h

Description

The p?geru routines perform a matrix-vector operation defined as

```
sub(A) := alpha*sub(x)*sub(y)' + sub(A),
```

where:

alpha is a scalar,

$\text{sub}(A)$ is a m -by- n distributed general matrix, $\text{sub}(A)=A(\text{ia}:\text{ia}+m-1, \text{ja}:\text{ja}+n-1)$,

$\text{sub}(x)$ is an m -element distributed vector, $\text{sub}(y)$ is an n -element distributed vector,

$\text{sub}(x)$ denotes $X(\text{ix}, \text{jx}:\text{jx}+m-1)$ if $\text{incx} = m\_x$, and $X(\text{ix}:\text{ix}+m-1, \text{jx})$ if $\text{incx} = 1$,

$\text{sub}(y)$ denotes $Y(\text{iy}, \text{jy}:\text{jy}+n-1)$ if $\text{incy} = m\_y$, and $Y(\text{iy}:\text{iy}+n-1, \text{jy})$ if $\text{incy} = 1$.

Input Parameters

<i>m</i>	(global) Specifies the number of rows of the distributed matrix $\text{sub}(A)$, $m \geq 0$.
<i>n</i>	(global) Specifies the number of columns of the distributed matrix $\text{sub}(A)$, $n \geq 0$.
<i>alpha</i>	(global) Specifies the scalar <i>alpha</i> .
<i>x</i>	(local) Array, size at least $(\text{jx}-1)*m\_x + \text{ix} + (n-1)*\text{abs}(\text{incx})$. This array contains the entries of the distributed vector $\text{sub}(x)$.
<i>ix, jx</i>	(global) The row and column indices in the distributed matrix X indicating the first row and the first column of the submatrix $\text{sub}(x)$, respectively.
<i>descx</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix X .
<i>incx</i>	(global) Specifies the increment for the elements of $\text{sub}(x)$. Only two values are supported, namely 1 and m_x . <i>incx</i> must not be zero.
<i>y</i>	(local) Array, size at least $(\text{jy}-1)*m\_y + \text{iy} + (n-1)*\text{abs}(\text{incy})$. This array contains the entries of the distributed vector $\text{sub}(y)$.
<i>iy, jy</i>	(global) The row and column indices in the distributed matrix Y indicating the first row and the first column of the submatrix $\text{sub}(y)$, respectively.
<i>descy</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix Y .
<i>incy</i>	(global) Specifies the increment for the elements of $\text{sub}(y)$. Only two values are supported, namely 1 and m_y . <i>incy</i> must not be zero.
<i>a</i>	(local) Array, size at least $(\text{lld\_a}, \text{LOCq}(\text{ja}+n-1))$. Before entry this array contains the local pieces of the distributed matrix $\text{sub}(A)$.
<i>ia, ja</i>	(global) The row and column indices in the distributed matrix A indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.

desca (global and local) array of dimension 9. The array descriptor of the distributed matrix *A*.

Output Parameters

a Overwritten by the updated distributed matrix *sub(A)*.

p?hemv

Computes a distributed matrix-vector product using a Hermitian matrix.

Syntax

```
void pchemv (char *uplo , MKL_INT *n , float *alpha , float *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , float *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx , MKL_INT
*incx , float *beta , float *y , MKL_INT *iy , MKL_INT *jy , MKL_INT *descy , MKL_INT
*incy );
```

```
void pzhemv (char *uplo , MKL_INT *n , double *alpha , double *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , double *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx , double *beta , double *y , MKL_INT *iy , MKL_INT *jy ,
MKL_INT *descy , MKL_INT *incy );
```

Include Files

- mkl_pblas.h

Description

The *p?hemv* routines perform a distributed matrix-vector operation defined as

$$\text{sub}(y) := \alpha * \text{sub}(A) * \text{sub}(x) + \beta * \text{sub}(y),$$

where:

alpha and *beta* are scalars,

sub(A) is a *n*-by-*n* Hermitian distributed matrix, *sub(A)* = *A*(*ia:ia+n-1*, *ja:ja+n-1*),

sub(x) and *sub(y)* are distributed vectors.

sub(x) denotes *X*(*ix*, *jx:jx+n-1*) if *incx* = *m_x*, and *X*(*ix: ix+n-1*, *jx*) if *incx* = 1,

sub(y) denotes *Y*(*iy*, *jy:jy+n-1*) if *incy* = *m_y*, and *Y*(*iy: iy+n-1*, *jy*) if *incy* = 1.

Input Parameters

uplo (global) Specifies whether the upper or lower triangular part of the Hermitian distributed matrix *sub(A)* is used:

If *uplo* = 'U' or 'u', then the upper triangular part of the *sub(A)* is used.

If *uplo* = 'L' or 'l', then the low triangular part of the *sub(A)* is used.

n (global) Specifies the order of the distributed matrix *sub(A)*, *n* ≥ 0.

alpha (global)
Specifies the scalar *alpha*.

<i>a</i>	(local) Array, size $(lld\_a, LOCq(ja+n-1))$. This array contains the local pieces of the distributed matrix $sub(A)$. Before entry when $uplo = 'U'$ or $'u'$, the n-by-n upper triangular part of the distributed matrix $sub(A)$ must contain the upper triangular part of the Hermitian distributed matrix and the strictly lower triangular part of $sub(A)$ is not referenced, and when $uplo = 'L'$ or $'l'$, the n-by-n lower triangular part of the distributed matrix $sub(A)$ must contain the lower triangular part of the Hermitian distributed matrix and the strictly upper triangular part of $sub(A)$ is not referenced.
<i>ia, ja</i>	(global) The row and column indices in the distributed matrix A indicating the first row and the first column of the submatrix $sub(A)$, respectively.
<i>desca</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix A.
<i>x</i>	(local) Array, size at least $(jx-1)*m\_x + ix + (n-1)*abs(incx)$. This array contains the entries of the distributed vector $sub(x)$.
<i>ix, jx</i>	(global) The row and column indices in the distributed matrix X indicating the first row and the first column of the submatrix $sub(x)$, respectively.
<i>descx</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix X.
<i>incx</i>	(global) Specifies the increment for the elements of $sub(x)$. Only two values are supported, namely 1 and m_x. $incx$ must not be zero.
<i>beta</i>	(global) Specifies the scalar $beta$. When $beta$ is set to zero, then $sub(y)$ need not be set on input.
<i>y</i>	(local) Array, size at least $(jy-1)*m\_y + iy + (n-1)*abs(incy)$. This array contains the entries of the distributed vector $sub(y)$.
<i>iy, jy</i>	(global) The row and column indices in the distributed matrix Y indicating the first row and the first column of the submatrix $sub(y)$, respectively.
<i>descy</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix Y.
<i>incy</i>	(global) Specifies the increment for the elements of $sub(y)$. Only two values are supported, namely 1 and m_y. $incy$ must not be zero.

Output Parameters

<i>y</i>	Overwritten by the updated distributed vector $sub(y)$.

p?ahemv

Computes a distributed matrix-vector product using absolute values for a Hermitian matrix.

Syntax

```
void pcahemv (char *uplo , MKL_INT *n , float *alpha , float *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , float *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx ,
MKL_INT *incx , float *beta , float *y , MKL_INT *iy , MKL_INT *jy , MKL_INT *descy ,
MKL_INT *incy );

void pzahemv (char *uplo , MKL_INT *n , double *alpha , double *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , double *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx , double *beta , double *y , MKL_INT *iy , MKL_INT *jy ,
MKL_INT *descy , MKL_INT *incy );
```

Include Files

- mkl_pblas.h

Description

The p?ahemv routines perform a distributed matrix-vector operation defined as

$$\text{sub}(y) := \text{abs}(\alpha) * \text{abs}(\text{sub}(A)) * \text{abs}(\text{sub}(x)) + \text{abs}(\beta * \text{sub}(y)),$$

where:

alpha and *beta* are scalars,

sub(A) is a *n*-by-*n* Hermitian distributed matrix, *sub(A)* = *A*(*ia*:*ia*+*n*-1, *ja*:*ja*+*n*-1) ,

sub(x) and *sub(y)* are distributed vectors.

sub(x) denotes *X*(*ix*, *jx*:*jx*+*n*-1) if *incx* = *m_x*, and *X*(*ix*: *ix*+*n*-1, *jx*) if *incx* = 1,

sub(y) denotes *Y*(*iy*, *jy*:*jy*+*n*-1) if *incy* = *m_y*, and *Y*(*iy*: *iy*+*n*-1, *jy*) if *incy* = 1.

Input Parameters

<i>uplo</i>	(global) Specifies whether the upper or lower triangular part of the Hermitian distributed matrix <i>sub(A)</i> is used: If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the <i>sub(A)</i> is used. If <i>uplo</i> = 'L' or 'l', then the low triangular part of the <i>sub(A)</i> is used.
<i>n</i>	(global) Specifies the order of the distributed matrix <i>sub(A)</i> , $n \geq 0$.
<i>alpha</i>	(global) Specifies the scalar <i>alpha</i> .
<i>a</i>	(local) Array, size (<i>lld_a</i> , LOCq(<i>ja</i> + <i>n</i> -1)). This array contains the local pieces of the distributed matrix <i>sub(A)</i> . Before entry when <i>uplo</i> = 'U' or 'u', the <i>n</i> -by- <i>n</i> upper triangular part of the distributed matrix <i>sub(A)</i> must contain the upper triangular part of the Hermitian distributed matrix and the strictly lower triangular part of <i>sub(A)</i>

is not referenced, and when `uplo = 'L'` or `'l'`, the n -by- n lower triangular part of the distributed matrix `sub(A)` must contain the lower triangular part of the Hermitian distributed matrix and the strictly upper triangular part of `sub(A)` is not referenced.

<code>ia, ja</code>	(global) The row and column indices in the distributed matrix <code>A</code> indicating the first row and the first column of the submatrix <code>sub(A)</code> , respectively.
<code>desca</code>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <code>A</code> .
<code>x</code>	(local) Array, size at least $(j_x-1)*m_x + i_x + (n-1)*abs(incx)$. This array contains the entries of the distributed vector <code>sub(x)</code> .
<code>ix, jx</code>	(global) The row and column indices in the distributed matrix <code>X</code> indicating the first row and the first column of the submatrix <code>sub(x)</code> , respectively.
<code>descx</code>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <code>X</code> .
<code>incx</code>	(global) Specifies the increment for the elements of <code>sub(x)</code> . Only two values are supported, namely 1 and <code>m_x</code> . <code>incx</code> must not be zero.
<code>beta</code>	(global) Specifies the scalar <code>beta</code> . When <code>beta</code> is set to zero, then <code>sub(y)</code> need not be set on input.
<code>y</code>	(local) Array, size at least $(j_y-1)*m_y + i_y + (n-1)*abs(incy)$. This array contains the entries of the distributed vector <code>sub(y)</code> .
<code>iy, jy</code>	(global) The row and column indices in the distributed matrix <code>Y</code> indicating the first row and the first column of the submatrix <code>sub(y)</code> , respectively.
<code>descy</code>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <code>Y</code> .
<code>incy</code>	(global) Specifies the increment for the elements of <code>sub(y)</code> . Only two values are supported, namely 1 and <code>m_y</code> . <code>incy</code> must not be zero.

Output Parameters

<code>y</code>	Overwritten by the updated distributed vector <code>sub(y)</code> .

p?her

Performs a rank-1 update of a distributed Hermitian matrix.

Syntax

```
void pcher (char *uplo , MKL_INT *n , float *alpha , float *x , MKL_INT *ix , MKL_INT
*jx , MKL_INT *descx , MKL_INT *incx , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca );
```

```
void pzher (char *uplo , MKL_INT *n , double *alpha , double *x , MKL_INT *ix ,
MKL_INT *jx , MKL_INT *descx , MKL_INT *incx , double *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca );
```

Include Files

- mkl_pblas.h

Description

The `p?her` routines perform a distributed matrix-vector operation defined as

$$\text{sub}(A) := \alpha * \text{sub}(x) * \text{conjg}(\text{sub}(x)') + \text{sub}(A),$$

where:

alpha is a real scalar,

`sub(A)` is a *n*-by-*n* distributed Hermitian matrix, `sub(A)=A(ia:ia+n-1, ja:ja+n-1)`,

`sub(x)` is distributed vector.

`sub(x)` denotes `X(ix, jx:jx+n-1)` if `incx = m_x`, and `X(ix: ix+n-1, jx)` if `incx = 1`.

Input Parameters

<i>uplo</i>	(global) Specifies whether the upper or lower triangular part of the Hermitian distributed matrix <code>sub(A)</code> is used: If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the <code>sub(A)</code> is used. If <i>uplo</i> = 'L' or 'l', then the low triangular part of the <code>sub(A)</code> is used.
<i>n</i>	(global) Specifies the order of the distributed matrix <code>sub(A)</code> , $n \geq 0$.
<i>alpha</i>	(global) Specifies the scalar <i>alpha</i> .
<i>x</i>	(local) Array, size at least $(jx-1) * m_x + ix + (n-1) * \text{abs}(incx)$. This array contains the entries of the distributed vector <code>sub(x)</code> .
<i>ix, jx</i>	(global) The row and column indices in the distributed matrix <code>X</code> indicating the first row and the first column of the submatrix <code>sub(x)</code> , respectively.
<i>descx</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <code>X</code> .
<i>incx</i>	(global) Specifies the increment for the elements of <code>sub(x)</code> . Only two values are supported, namely 1 and m_x . <i>incx</i> must not be zero.
<i>a</i>	(local)

Array, size $(lld\_a, LOCq(ja+n-1))$. This array contains the local pieces of the distributed matrix $sub(A)$.

Before entry with $uplo = 'U'$ or $'u'$, the n -by- n upper triangular part of the distributed matrix $sub(A)$ must contain the upper triangular part of the Hermitian distributed matrix and the strictly lower triangular part of $sub(A)$ is not referenced, and with $uplo = 'L'$ or $'l'$, the n -by- n lower triangular part of the distributed matrix $sub(A)$ must contain the lower triangular part of the Hermitian distributed matrix and the strictly upper triangular part of $sub(A)$ is not referenced.

ia, ja

(global) The row and column indices in the distributed matrix A indicating the first row and the first column of the submatrix $sub(A)$, respectively.

desca

(global and local) array of dimension 9. The array descriptor of the distributed matrix A .

Output Parameters

a

With $uplo = 'U'$ or $'u'$, the upper triangular part of the array a is overwritten by the upper triangular part of the updated distributed matrix $sub(A)$.

With $uplo = 'L'$ or $'l'$, the lower triangular part of the array a is overwritten by the lower triangular part of the updated distributed matrix $sub(A)$.

p?her2

Performs a rank-2 update of a distributed Hermitian matrix.

Syntax

```
void pcher2 (char *uplo , MKL_INT *n , float *alpha , float *x , MKL_INT *ix , MKL_INT
*jx , MKL_INT *descx , MKL_INT *incx , float *y , MKL_INT *iy , MKL_INT *jy , MKL_INT
*descy , MKL_INT *incy , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );
```

```
void pzher2 (char *uplo , MKL_INT *n , double *alpha , double *x , MKL_INT *ix ,
MKL_INT *jx , MKL_INT *descx , MKL_INT *incx , double *y , MKL_INT *iy , MKL_INT *jy ,
MKL_INT *descy , MKL_INT *incy , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca );
```

Include Files

- mkl_pblas.h

Description

The `p?her2` routines perform a distributed matrix-vector operation defined as

$$sub(A) := \alpha * sub(x) * conj(sub(y)') + conj(\alpha) * sub(y) * conj(sub(x)') + sub(A),$$

where:

α is a scalar,

$sub(A)$ is a n -by- n distributed Hermitian matrix, $sub(A) = A(ia:ia+n-1, ja:ja+n-1)$,

$sub(x)$ and $sub(y)$ are distributed vectors.

$\text{sub}(x)$ denotes $X(ix, jx:jx+n-1)$ if $incx = m\_x$, and $X(ix: ix+n-1, jx)$ if $incx = 1$,

$\text{sub}(y)$ denotes $Y(iy, jy:jy+n-1)$ if $incy = m\_y$, and $Y(iy: iy+n-1, jy)$ if $incy = 1$.

Input Parameters

<i>uplo</i>	(global) Specifies whether the upper or lower triangular part of the distributed Hermitian matrix $\text{sub}(A)$ is used: If $uplo = 'U'$ or $'u'$, then the upper triangular part of the $\text{sub}(A)$ is used. If $uplo = 'L'$ or $'l'$, then the low triangular part of the $\text{sub}(A)$ is used.
<i>n</i>	(global) Specifies the order of the distributed matrix $\text{sub}(A)$, $n \geq 0$.
<i>alpha</i>	(global) Specifies the scalar <i>alpha</i>.
<i>x</i>	(local) Array, size at least $(jx-1)*m\_x + ix+(n-1)*abs(incx)$. This array contains the entries of the distributed vector $\text{sub}(x)$.
<i>ix, jx</i>	(global) The row and column indices in the distributed matrix X indicating the first row and the first column of the submatrix $\text{sub}(x)$, respectively.
<i>descx</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix X .
<i>incx</i>	(global) Specifies the increment for the elements of $\text{sub}(x)$. Only two values are supported, namely 1 and m_x . <i>incx</i> must not be zero.
<i>y</i>	(local) Array, size at least $(jy-1)*m\_y + iy+(n-1)*abs(incy)$. This array contains the entries of the distributed vector $\text{sub}(y)$.
<i>iy, jy</i>	(global) The row and column indices in the distributed matrix Y indicating the first row and the first column of the submatrix $\text{sub}(y)$, respectively.
<i>descy</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix Y .
<i>incy</i>	(global) Specifies the increment for the elements of $\text{sub}(y)$. Only two values are supported, namely 1 and m_y . <i>incy</i> must not be zero.
<i>a</i>	(local) Array, size $(lld\_a, LOCq(ja+n-1))$. This array contains the local pieces of the distributed matrix $\text{sub}(A)$. Before entry with $uplo = 'U'$ or $'u'$, the n-by-n upper triangular part of the distributed matrix $\text{sub}(A)$ must contain the upper triangular part of the Hermitian distributed matrix and the strictly lower triangular part of $\text{sub}(A)$ is not referenced, and with $uplo = 'L'$ or $'l'$, the n-by-n lower triangular

part of the distributed matrix $\text{sub}(A)$ must contain the lower triangular part of the Hermitian distributed matrix and the strictly upper triangular part of $\text{sub}(A)$ is not referenced.

ia, ja

(global) The row and column indices in the distributed matrix A indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.

desca

(global and local) array of dimension 9. The array descriptor of the distributed matrix A .

Output Parameters

a

With *uplo* = 'U' or 'u', the upper triangular part of the array *a* is overwritten by the upper triangular part of the updated distributed matrix $\text{sub}(A)$.

With *uplo* = 'L' or 'l', the lower triangular part of the array *a* is overwritten by the lower triangular part of the updated distributed matrix $\text{sub}(A)$.

p?symv

Computes a distributed matrix-vector product using a symmetric matrix.

Syntax

```
void pssymv (char *uplo , MKL_INT *n , float *alpha , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx , MKL_INT *incx , float *beta , float *y , MKL_INT *iy , MKL_INT *jy , MKL_INT *descy , MKL_INT *incy );
```

```
void pdsymv (char *uplo , MKL_INT *n , double *alpha , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx , MKL_INT *incx , double *beta , double *y , MKL_INT *iy , MKL_INT *jy , MKL_INT *descy , MKL_INT *incy );
```

Include Files

- mkl_pblas.h

Description

The *p?symv* routines perform a distributed matrix-vector operation defined as

$$\text{sub}(y) := \alpha \text{sub}(A) \text{sub}(x) + \beta \text{sub}(y),$$

where:

alpha and *beta* are scalars,

$\text{sub}(A)$ is a n -by- n symmetric distributed matrix, $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$,

$\text{sub}(x)$ and $\text{sub}(y)$ are distributed vectors.

$\text{sub}(x)$ denotes $X(\text{ix}, \text{jx}:\text{jx}+n-1)$ if $\text{incx} = m_x$, and $X(\text{ix}:\text{ix}+n-1, \text{jx})$ if $\text{incx} = 1$,

$\text{sub}(y)$ denotes $Y(\text{iy}, \text{jy}:\text{jy}+n-1)$ if $\text{incy} = m_y$, and $Y(\text{iy}:\text{iy}+n-1, \text{jy})$ if $\text{incy} = 1$.

Input Parameters

<i>uplo</i>	(global) Specifies whether the upper or lower triangular part of the symmetric distributed matrix $\text{sub}(A)$ is used: If $\text{uplo} = 'U'$ or $'u'$, then the upper triangular part of the $\text{sub}(A)$ is used. If $\text{uplo} = 'L'$ or $'l'$, then the low triangular part of the $\text{sub}(A)$ is used.
<i>n</i>	(global) Specifies the order of the distributed matrix $\text{sub}(A)$, $n \geq 0$.
<i>alpha</i>	(global) Specifies the scalar <i>alpha</i>.
<i>a</i>	(local) Array, size $(\text{lld\_a}, \text{LOCq}(ja+n-1))$. This array contains the local pieces of the distributed matrix $\text{sub}(A)$. Before entry when $\text{uplo} = 'U'$ or $'u'$, the n-by-n upper triangular part of the distributed matrix $\text{sub}(A)$ must contain the upper triangular part of the symmetric distributed matrix and the strictly lower triangular part of $\text{sub}(A)$ is not referenced, and when $\text{uplo} = 'L'$ or $'l'$, the n-by-n lower triangular part of the distributed matrix $\text{sub}(A)$ must contain the lower triangular part of the symmetric distributed matrix and the strictly upper triangular part of $\text{sub}(A)$ is not referenced.
<i>ia, ja</i>	(global) The row and column indices in the distributed matrix A indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix A .
<i>x</i>	(local) Array, size at least $(jx-1)*m_x + ix + (n-1)*\text{abs}(incx)$. This array contains the entries of the distributed vector $\text{sub}(x)$.
<i>ix, jx</i>	(global) The row and column indices in the distributed matrix X indicating the first row and the first column of the submatrix $\text{sub}(x)$, respectively.
<i>descx</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix X .
<i>incx</i>	(global) Specifies the increment for the elements of $\text{sub}(x)$. Only two values are supported, namely 1 and m_x . $incx$ must not be zero.
<i>beta</i>	(global) Specifies the scalar <i>beta</i>. When <i>beta</i> is set to zero, then $\text{sub}(y)$ need not be set on input.
<i>y</i>	(local) Array, size at least $(jy-1)*m_y + iy + (n-1)*\text{abs}(incy)$. This array contains the entries of the distributed vector $\text{sub}(y)$.

<i>iy, jy</i>	(global) The row and column indices in the distributed matrix <i>Y</i> indicating the first row and the first column of the submatrix <i>sub(Y)</i> , respectively.
<i>descy</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>Y</i> .
<i>incy</i>	(global) Specifies the increment for the elements of <i>sub(Y)</i> . Only two values are supported, namely 1 and <i>m_y</i> . <i>incy</i> must not be zero.

Output Parameters

<i>y</i>	Overwritten by the updated distributed vector <i>sub(y)</i> .

p?asymv

Computes a distributed matrix-vector product using absolute values for a symmetric matrix.

Syntax

```
void psasymv (char *uplo , MKL_INT *n , float *alpha , float *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , float *x , MKL_INT *ix , MKL_INT *jx , MKL_INT *descx ,
MKL_INT *incx , float *beta , float *y , MKL_INT *iy , MKL_INT *jy , MKL_INT *descy ,
MKL_INT *incy );

void pdasymv (char *uplo , MKL_INT *n , double *alpha , double *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , double *x , MKL_INT *ix , MKL_INT *jx , MKL_INT

MKL_INT *descy , MKL_INT *incy );
```

Include Files

- mkl_pblas.h

Description

The *p?symv* routines perform a distributed matrix-vector operation defined as

$$\text{sub}(y) := \text{abs}(\alpha) * \text{abs}(\text{sub}(A)) * \text{abs}(\text{sub}(x)) + \text{abs}(\beta * \text{sub}(y)),$$

where:

alpha and *beta* are scalars,

sub(A) is a *n*-by-*n* symmetric distributed matrix, *sub(A)* = *A(ia:ia+n-1, ja:ja+n-1)*,

sub(x) and *sub(y)* are distributed vectors.

sub(x) denotes *X(ix, jx:jx+n-1)* if *incx* = *m_x*, and *X(ix: ix+n-1, jx)* if *incx* = 1,

sub(y) denotes *Y(iy, jy:jy+n-1)* if *incy* = *m_y*, and *Y(iy: iy+n-1, jy)* if *incy* = 1.

Input Parameters

<i>uplo</i>	(global) Specifies whether the upper or lower triangular part of the symmetric distributed matrix <i>sub(A)</i> is used: If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the <i>sub(A)</i> is used.

	If <code>uplo = 'L' or 'l'</code> , then the low triangular part of the <code>sub(A)</code> is used.
<code>n</code>	(global) Specifies the order of the distributed matrix <code>sub(A)</code> , $n \geq 0$.
<code>alpha</code>	(global) Specifies the scalar <code>alpha</code> .
<code>a</code>	(local) Array, size <code>(lld_a, LOCq(ja+n-1))</code> . This array contains the local pieces of the distributed matrix <code>sub(A)</code> . Before entry when <code>uplo = 'U' or 'u'</code> , the n -by- n upper triangular part of the distributed matrix <code>sub(A)</code> must contain the upper triangular part of the symmetric distributed matrix and the strictly lower triangular part of <code>sub(A)</code> is not referenced, and when <code>uplo = 'L' or 'l'</code> , the n -by- n lower triangular part of the distributed matrix <code>sub(A)</code> must contain the lower triangular part of the symmetric distributed matrix and the strictly upper triangular part of <code>sub(A)</code> is not referenced.
<code>ia, ja</code>	(global) The row and column indices in the distributed matrix <code>A</code> indicating the first row and the first column of the submatrix <code>sub(A)</code> , respectively.
<code>desca</code>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <code>A</code> .
<code>x</code>	(local) Array, size at least <code>(jx-1)*m_x + ix+(n-1)*abs(incx)</code> . This array contains the entries of the distributed vector <code>sub(x)</code> .
<code>ix, jx</code>	(global) The row and column indices in the distributed matrix <code>X</code> indicating the first row and the first column of the submatrix <code>sub(x)</code> , respectively.
<code>descx</code>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <code>X</code> .
<code>incx</code>	(global) Specifies the increment for the elements of <code>sub(x)</code> . Only two values are supported, namely 1 and <code>m_x</code> . <code>incx</code> must not be zero.
<code>beta</code>	(global) Specifies the scalar <code>beta</code> . When <code>beta</code> is set to zero, then <code>sub(y)</code> need not be set on input.
<code>y</code>	(local) Array, size at least <code>(jy-1)*m_y + iy+(n-1)*abs(incy)</code> . This array contains the entries of the distributed vector <code>sub(y)</code> .
<code>iy, jy</code>	(global) The row and column indices in the distributed matrix <code>Y</code> indicating the first row and the first column of the submatrix <code>sub(y)</code> , respectively.
<code>descy</code>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <code>Y</code> .

incy (global) Specifies the increment for the elements of $\text{sub}(y)$. Only two values are supported, namely 1 and m_y . *incy* must not be zero.

Output Parameters

y Overwritten by the updated distributed vector $\text{sub}(y)$.

p?syr

Performs a rank-1 update of a distributed symmetric matrix.

Syntax

```
void pssyr (char *uplo , MKL_INT *n , float *alpha , float *x , MKL_INT *ix , MKL_INT
*jx , MKL_INT *descx , MKL_INT *incx , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT
*desca );
```

```
void pdsyr (char *uplo , MKL_INT *n , double *alpha , double *x , MKL_INT *ix ,
MKL_INT *jx , MKL_INT *descx , MKL_INT *incx , double *a , MKL_INT *ia , MKL_INT *ja ,
MKL_INT *desca );
```

Include Files

- mkl_pblas.h

Description

The *p?syr* routines perform a distributed matrix-vector operation defined as

$$\text{sub}(A) := \alpha \text{sub}(x) \text{sub}(x)^T + \text{sub}(A),$$

where:

alpha is a scalar,

$\text{sub}(A)$ is a n -by- n distributed symmetric matrix, $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1)$,

$\text{sub}(x)$ is distributed vector.

$\text{sub}(x)$ denotes $X(ix, jx:jx+n-1)$ if $incx = m_x$, and $X(ix:ix+n-1, jx)$ if $incx = 1$,

Input Parameters

uplo (global) Specifies whether the upper or lower triangular part of the symmetric distributed matrix $\text{sub}(A)$ is used:

If *uplo* = 'U' or 'u', then the upper triangular part of the $\text{sub}(A)$ is used.

If *uplo* = 'L' or 'l', then the low triangular part of the $\text{sub}(A)$ is used.

n (global) Specifies the order of the distributed matrix $\text{sub}(A)$, $n \geq 0$.

alpha (global)
Specifies the scalar *alpha*.

x (local)
Array, size at least $(jx-1) * m_x + ix + (n-1) * \text{abs}(incx)$.

	This array contains the entries of the distributed vector <code>sub(x)</code> .
<code>ix, jx</code>	(global) The row and column indices in the distributed matrix <code>X</code> indicating the first row and the first column of the submatrix <code>sub(x)</code> , respectively.
<code>descx</code>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <code>X</code> .
<code>incx</code>	(global) Specifies the increment for the elements of <code>sub(x)</code> . Only two values are supported, namely 1 and <code>m_x</code> . <code>incx</code> must not be zero.
<code>a</code>	(local) Array, size <code>(lld_a, LOCq(ja+n-1))</code>. This array contains the local pieces of the distributed matrix <code>sub(A)</code>. Before entry with <code>uplo = 'U' or 'u'</code>, the n-by-n upper triangular part of the distributed matrix <code>sub(A)</code> must contain the upper triangular part of the symmetric distributed matrix and the strictly lower triangular part of <code>sub(A)</code> is not referenced, and with <code>uplo = 'L' or 'l'</code>, the n-by-n lower triangular part of the distributed matrix <code>sub(A)</code> must contain the lower triangular part of the symmetric distributed matrix and the strictly upper triangular part of <code>sub(A)</code> is not referenced.
<code>ia, ja</code>	(global) The row and column indices in the distributed matrix <code>A</code> indicating the first row and the first column of the submatrix <code>sub(A)</code> , respectively.
<code>desca</code>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <code>A</code> .

Output Parameters

<code>a</code>	With <code>uplo = 'U' or 'u'</code>, the upper triangular part of the array <code>a</code> is overwritten by the upper triangular part of the updated distributed matrix <code>sub(A)</code>. With <code>uplo = 'L' or 'l'</code>, the lower triangular part of the array <code>a</code> is overwritten by the lower triangular part of the updated distributed matrix <code>sub(A)</code>.

p?syr2

Performs a rank-2 update of a distributed symmetric matrix.

Syntax

```
void pssyr2 (char *uplo , MKL_INT *n , float *alpha , float *x , MKL_INT *ix , MKL_INT
*jx , MKL_INT *descx , MKL_INT *incx , float *y , MKL_INT *iy , MKL_INT *jy , MKL_INT
*descy , MKL_INT *incy , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca );

void pdsyr2 (char *uplo , MKL_INT *n , double *alpha , double *x , MKL_INT *ix ,
MKL_INT *jx , MKL_INT *descx , MKL_INT *incx , double *y , MKL_INT *iy , MKL_INT *jy ,

Description

The `p?syrr2` routines perform a distributed matrix-vector operation defined as

$$\text{sub}(A) := \alpha * \text{sub}(x) * \text{sub}(y)' + \alpha * \text{sub}(y) * \text{sub}(x)' + \text{sub}(A),$$

where:

alpha is a scalar,

sub(A) is a *n*-by-*n* distributed symmetric matrix, *sub(A)* = *A*(*ia:ia+n-1*, *ja:ja+n-1*),

sub(x) and *sub(y)* are distributed vectors.

sub(x) denotes *X*(*ix*, *jx:jx+n-1*) if *incx* = *m_x*, and *X*(*ix:ix+n-1*, *jx*) if *incx* = 1,

sub(y) denotes *Y*(*iy*, *jy:jy+n-1*) if *incy* = *m_y*, and *Y*(*iy:iy+n-1*, *jy*) if *incy* = 1.

Input Parameters

<i>uplo</i>	(global) Specifies whether the upper or lower triangular part of the distributed symmetric matrix <i>sub(A)</i> is used: If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the <i>sub(A)</i> is used. If <i>uplo</i> = 'L' or 'l', then the low triangular part of the <i>sub(A)</i> is used.
<i>n</i>	(global) Specifies the order of the distributed matrix <i>sub(A)</i> , $n \geq 0$.
<i>alpha</i>	(global) Specifies the scalar <i>alpha</i> .
<i>x</i>	(local) Array, size at least $(jx-1)*m_x + ix + (n-1)*abs(incx)$. This array contains the entries of the distributed vector <i>sub(x)</i> .
<i>ix, jx</i>	(global) The row and column indices in the distributed matrix <i>X</i> indicating the first row and the first column of the submatrix <i>sub(x)</i> , respectively.
<i>descx</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>X</i> .
<i>incx</i>	(global) Specifies the increment for the elements of <i>sub(x)</i> . Only two values are supported, namely 1 and <i>m_x</i> . <i>incx</i> must not be zero.
<i>y</i>	(local) Array, size at least $(jy-1)*m_y + iy + (n-1)*abs(incy)$. This array contains the entries of the distributed vector <i>sub(y)</i> .
<i>iy, jy</i>	(global) The row and column indices in the distributed matrix <i>Y</i> indicating the first row and the first column of the submatrix <i>sub(y)</i> , respectively.
<i>descy</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>Y</i> .

<i>incy</i>	(global) Specifies the increment for the elements of <code>sub(y)</code> . Only two values are supported, namely 1 and <code>m_y.incy</code> . <code>incy</code> must not be zero.
<i>a</i>	(local) Array, size <code>(lld_a, LOCq(ja+n-1))</code> . This array contains the local pieces of the distributed matrix <code>sub(A)</code> . Before entry with <code>uplo = 'U' or 'u'</code> , the n -by- n upper triangular part of the distributed matrix <code>sub(A)</code> must contain the upper triangular part of the distributed symmetric matrix and the strictly lower triangular part of <code>sub(A)</code> is not referenced, and with <code>uplo = 'L' or 'l'</code> , the n -by- n lower triangular part of the distributed matrix <code>sub(A)</code> must contain the lower triangular part of the distributed symmetric matrix and the strictly upper triangular part of <code>sub(A)</code> is not referenced.
<i>ia, ja</i>	(global) The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix <code>sub(A)</code> , respectively.
<i>desca</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .

Output Parameters

<i>a</i>	With <code>uplo = 'U' or 'u'</code> , the upper triangular part of the array <i>a</i> is overwritten by the upper triangular part of the updated distributed matrix <code>sub(A)</code> . With <code>uplo = 'L' or 'l'</code> , the lower triangular part of the array <i>a</i> is overwritten by the lower triangular part of the updated distributed matrix <code>sub(A)</code> .

p?trmv

Computes a distributed matrix-vector product using a triangular matrix.

Syntax

```
void pstrmv (char *uplo , char *trans , char *diag , MKL_INT *n , float *a , MKL_INT
*ia , MKL_INT *ja , MKL_INT *desca , float *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx );

void pdtrmv (char *uplo , char *trans , char *diag , MKL_INT *n , double *a , MKL_INT
*ia , MKL_INT *ja , MKL_INT *desca , double *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx );

void pctrmv (char *uplo , char *trans , char *diag , MKL_INT *n , float *a , MKL_INT
*ia , MKL_INT *ja , MKL_INT *desca , float *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx );

void pztrmv (char *uplo , char *trans , char *diag , MKL_INT *n , double *a , MKL_INT
*ia , MKL_INT *ja , MKL_INT *desca , double *x , MKL_INT *ix , MKL_INT *jx , MKL_INT

```

Include Files

- `mkl_pblas.h`

Description

The `p?trmv` routines perform one of the following distributed matrix-vector operations defined as

`sub(x) := sub(A)*sub(x)`, or `sub(x) :=sub( A )'*sub(x)`, or `sub(x) := conjg(sub(A)')*sub(x)`,

where:

`sub(A)` is a n -by- n unit, or non-unit, upper or lower triangular distributed matrix, `sub(A) = A(ia:ia+n-1, ja:ja+n-1)`,

`sub(x)` is an n -element distributed vector.

`sub(x)` denotes `X(ix, jx:jx+n-1)` if `incx = m_x`, and `X(ix: ix+n-1, jx)` if `incx = 1`,

Input Parameters

<i>uplo</i>	(global) Specifies whether the distributed matrix <code>sub(A)</code> is upper or lower triangular: if <code>uplo = 'U' or 'u'</code> , then the matrix is upper triangular; if <code>uplo = 'L' or 'l'</code> , then the matrix is low triangular.
<i>trans</i>	(global) Specifies the form of <code>op(sub(A))</code> used in the matrix equation: if <code>transa = 'N' or 'n'</code> , then <code>sub(x) := sub(A)*sub(x)</code> ; if <code>transa = 'T' or 't'</code> , then <code>sub(x) :=sub(A)'*sub(x)</code> ; if <code>transa = 'C' or 'c'</code> , then <code>sub(x) := conjg(sub(A)')*sub(x)</code> .
<i>diag</i>	(global) Specifies whether the matrix <code>sub(A)</code> is unit triangular: if <code>diag = 'U' or 'u'</code> then the matrix is unit triangular; if <code>diag = 'N' or 'n'</code> , then the matrix is not unit triangular.
<i>n</i>	(global) Specifies the order of the distributed matrix <code>sub(A)</code> , $n \geq 0$.
<i>a</i>	(local) Array, size at least <code>(lld_a, LOCq(1, ja+n-1))</code> . Before entry with <code>uplo = 'U' or 'u'</code> , this array contains the local entries corresponding to the entries of the upper triangular distributed matrix <code>sub(A)</code> , and the local entries corresponding to the entries of the strictly lower triangular part of the distributed matrix <code>sub(A)</code> is not referenced. Before entry with <code>uplo = 'L' or 'l'</code> , this array contains the local entries corresponding to the entries of the lower triangular distributed matrix <code>sub(A)</code> , and the local entries corresponding to the entries of the strictly upper triangular part of the distributed matrix <code>sub(A)</code> is not referenced . When <code>diag = 'U' or 'u'</code> , the local entries corresponding to the diagonal elements of the submatrix <code>sub(A)</code> are not referenced either, but are assumed to be unity.
<i>ia, ja</i>	(global) The row and column indices in the distributed matrix <code>A</code> indicating the first row and the first column of the submatrix <code>sub(A)</code> , respectively.

<i>desca</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .
<i>x</i>	(local) Array, size at least $(j_x-1)*m_x + ix + (n-1)*abs(incx)$. This array contains the entries of the distributed vector <i>sub(x)</i> .
<i>ix, jx</i>	(global) The row and column indices in the distributed matrix <i>X</i> indicating the first row and the first column of the submatrix <i>sub(x)</i> , respectively.
<i>descx</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>X</i> .
<i>incx</i>	(global) Specifies the increment for the elements of <i>sub(x)</i> . Only two values are supported, namely 1 and <i>m_x</i> . <i>incx</i> must not be zero.

Output Parameters

<i>x</i>	Overwritten by the transformed distributed vector <i>sub(x)</i> .

p?atrmv

Computes a distributed matrix-vector product using absolute values for a triangular matrix.

Syntax

```
void psatrmv (char *uplo , char *trans , char *diag , MKL_INT *n , float *alpha ,
float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *x , MKL_INT *ix ,
MKL_INT *jx , MKL_INT *descx , MKL_INT *incx , float *beta , float *y , MKL_INT *iy ,
MKL_INT *jy , MKL_INT *descy , MKL_INT *incy );
```

```
void pdatrmv (char *uplo , char *trans , char *diag , MKL_INT *n , double *alpha ,
double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *x , MKL_INT *ix ,
MKL_INT *jx , MKL_INT *descx , MKL_INT *incx , double *beta , double *y , MKL_INT
*iy , MKL_INT *jy , MKL_INT *descy , MKL_INT *incy );
```

```
void pcatrmv (char *uplo , char *trans , char *diag , MKL_INT *n , float *alpha ,

Description

The *p?atrmv* routines perform one of the following distributed matrix-vector operations defined as

*sub(y) := abs(alpha)*abs(sub(A))*abs(sub(x)) + abs(beta*sub(y))*, or

*sub(y) := abs(alpha)*abs(sub(A'))*abs(sub(x)) + abs(beta*sub(y))*, or

$\text{sub}(y) := \text{abs}(\alpha) * \text{abs}(\text{conjg}(\text{sub}(A))) * \text{abs}(\text{sub}(x)) + \text{abs}(\beta * \text{sub}(y))$,

where:

α and β are scalars,

$\text{sub}(A)$ is a n -by- n unit, or non-unit, upper or lower triangular distributed matrix, $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$,

$\text{sub}(x)$ is an n -element distributed vector.

$\text{sub}(x)$ denotes $X(\text{ix}, \text{jx}:\text{jx}+n-1)$ if $\text{incx} = m\_x$, and $X(\text{ix}:\text{ix}+n-1, \text{jx})$ if $\text{incx} = 1$.

Input Parameters

<i>uplo</i>	(global) Specifies whether the distributed matrix $\text{sub}(A)$ is upper or lower triangular: if <i>uplo</i> = 'U' or 'u', then the matrix is upper triangular; if <i>uplo</i> = 'L' or 'l', then the matrix is low triangular.
<i>trans</i>	(global) Specifies the form of $\text{op}(\text{sub}(A))$ used in the matrix equation: if <i>trans</i> = 'N' or 'n', then $\text{sub}(y) := \alpha * \text{sub}(A) * \text{sub}(x) + \beta * \text{sub}(y) $; if <i>trans</i> = 'T' or 't', then $\text{sub}(y) := \alpha * \text{sub}(A)^T * \text{sub}(x) + \beta * \text{sub}(y) $; if <i>trans</i> = 'C' or 'c', then $\text{sub}(y) := \alpha * \text{conjg}(\text{sub}(A)) * \text{sub}(x) + \beta * \text{sub}(y) $.
<i>diag</i>	(global) Specifies whether the matrix $\text{sub}(A)$ is unit triangular: if <i>diag</i> = 'U' or 'u' then the matrix is unit triangular; if <i>diag</i> = 'N' or 'n', then the matrix is not unit triangular.
<i>n</i>	(global) Specifies the order of the distributed matrix $\text{sub}(A)$, $n \geq 0$.
<i>alpha</i>	(global) Specifies the scalar α .
<i>a</i>	(local) Array, size at least $(\text{lld\_a}, \text{LOCq}(1, \text{ja}+n-1))$. Before entry with <i>uplo</i> = 'U' or 'u', this array contains the local entries corresponding to the entries of the upper triangular distributed matrix $\text{sub}(A)$, and the local entries corresponding to the entries of the strictly lower triangular part of the distributed matrix $\text{sub}(A)$ is not referenced. Before entry with <i>uplo</i> = 'L' or 'l', this array contains the local entries corresponding to the entries of the lower triangular distributed matrix $\text{sub}(A)$, and the local entries corresponding to the entries of the strictly upper triangular part of the distributed matrix $\text{sub}(A)$ is not referenced. When <i>diag</i> = 'U' or 'u', the local entries corresponding to the diagonal elements of the submatrix $\text{sub}(A)$ are not referenced either, but are assumed to be unity.

<i>ia, ja</i>	(global) The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix <code>sub(A)</code> , respectively.
<i>desca</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .
<i>x</i>	(local) Array, size at least $(j_x-1)*m_x + ix + (n-1)*abs(incx)$. This array contains the entries of the distributed vector <code>sub(x)</code> .
<i>ix, jx</i>	(global) The row and column indices in the distributed matrix <i>X</i> indicating the first row and the first column of the submatrix <code>sub(x)</code> , respectively.
<i>descx</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>X</i> .
<i>incx</i>	(global) Specifies the increment for the elements of <code>sub(x)</code> . Only two values are supported, namely 1 and m_x . <i>incx</i> must not be zero.
<i>beta</i>	(global) Specifies the scalar <i>beta</i> . When <i>beta</i> is set to zero, then <code>sub(y)</code> need not be set on input.
<i>y</i>	(local) Array, size $(j_y-1)*m_y + iy + (m-1)*abs(incy)$ when <i>trans</i> = 'N' or 'n', and $(j_y-1)*m_y + iy + (n-1)*abs(incy)$ otherwise. This array contains the entries of the distributed vector <code>sub(y)</code> .
<i>iy, jy</i>	(global) The row and column indices in the distributed matrix <i>Y</i> indicating the first row and the first column of the submatrix <code>sub(y)</code> , respectively.
<i>descy</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>Y</i> .
<i>incy</i>	(global) Specifies the increment for the elements of <code>sub(y)</code> . Only two values are supported, namely 1 and m_y . <i>incy</i> must not be zero.

Output Parameters

<i>y</i>	Overwritten by the transformed distributed vector <code>sub(y)</code> .

p?trsv

Solves a system of linear equations whose coefficients are in a distributed triangular matrix.

Syntax

```
void pstrsv (char *uplo , char *trans , char *diag , MKL_INT *n , float *a , MKL_INT
*ia , MKL_INT *ja , MKL_INT *desca , float *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx );
```

```

void pdtrsv (char *uplo , char *trans , char *diag , MKL_INT *n , double *a , MKL_INT
*ia , MKL_INT *ja , MKL_INT *desca , double *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx );

void pctrsv (char *uplo , char *trans , char *diag , MKL_INT *n , float *a , MKL_INT
*ia , MKL_INT *ja , MKL_INT *desca , float *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx );

void pztrsv (char *uplo , char *trans , char *diag , MKL_INT *n , double *a , MKL_INT
*ia , MKL_INT *ja , MKL_INT *desca , double *x , MKL_INT *ix , MKL_INT *jx , MKL_INT
*descx , MKL_INT *incx );

```

Include Files

- mkl_pblas.h

Description

The `p?trsv` routines solve one of the systems of equations:

$\text{sub}(A) * \text{sub}(x) = b$, or $\text{sub}(A)' * \text{sub}(x) = b$, or $\text{conjg}(\text{sub}(A)') * \text{sub}(x) = b$,

where:

$\text{sub}(A)$ is a n -by- n unit, or non-unit, upper or lower triangular distributed matrix, $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+n-1)$,

b and $\text{sub}(x)$ are n -element distributed vectors,

$\text{sub}(x)$ denotes $X(\text{ix}, \text{jx}:\text{jx}+n-1)$ if $\text{incx} = m\_x$, and $X(\text{ix}:\text{ix}+n-1, \text{jx})$ if $\text{incx} = 1$.

The routine does not test for singularity or near-singularity. Such tests must be performed before calling this routine.

Input Parameters

<i>uplo</i>	(global) Specifies whether the distributed matrix $\text{sub}(A)$ is upper or lower triangular: if <i>uplo</i> = 'U' or 'u', then the matrix is upper triangular; if <i>uplo</i> = 'L' or 'l', then the matrix is low triangular.
<i>trans</i>	(global) Specifies the form of the system of equations: if <i>transa</i> = 'N' or 'n', then $\text{sub}(A) * \text{sub}(x) = b$; if <i>transa</i> = 'T' or 't', then $\text{sub}(A)' * \text{sub}(x) = b$; if <i>transa</i> = 'C' or 'c', then $\text{conjg}(\text{sub}(A)') * \text{sub}(x) = b$.
<i>diag</i>	(global) Specifies whether the matrix $\text{sub}(A)$ is unit triangular: if <i>diag</i> = 'U' or 'u' then the matrix is unit triangular; if <i>diag</i> = 'N' or 'n', then the matrix is not unit triangular.
<i>n</i>	(global) Specifies the order of the distributed matrix $\text{sub}(A)$, $n \geq 0$.
<i>a</i>	(local) Array, size at least $(\text{lld\_a}, \text{LOCq}(1, \text{ja}+n-1))$.

Before entry with `uplo = 'U' or 'u'`, this array contains the local entries corresponding to the entries of the upper triangular distributed matrix `sub(A)`, and the local entries corresponding to the entries of the strictly lower triangular part of the distributed matrix `sub(A)` is not referenced.

Before entry with `uplo = 'L' or 'l'`, this array contains the local entries corresponding to the entries of the lower triangular distributed matrix `sub(A)`, and the local entries corresponding to the entries of the strictly upper triangular part of the distributed matrix `sub(A)` is not referenced.

When `diag = 'U' or 'u'`, the local entries corresponding to the diagonal elements of the submatrix `sub(A)` are not referenced either, but are assumed to be unity.

<code>ia, ja</code>	(global) The row and column indices in the distributed matrix <code>A</code> indicating the first row and the first column of the submatrix <code>sub(A)</code> , respectively.
<code>desca</code>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <code>A</code> .
<code>x</code>	(local) Array, size at least $(jx-1)*m_x + ix + (n-1)*abs(incx)$. This array contains the entries of the distributed vector <code>sub(x)</code> . Before entry, <code>sub(x)</code> must contain the n -element right-hand side distributed vector <code>b</code> .
<code>ix, jx</code>	(global) The row and column indices in the distributed matrix <code>X</code> indicating the first row and the first column of the submatrix <code>sub(x)</code> , respectively.
<code>descx</code>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <code>X</code> .
<code>incx</code>	(global) Specifies the increment for the elements of <code>sub(x)</code> . Only two values are supported, namely 1 and m_x . <code>incx</code> must not be zero.

Output Parameters

<code>x</code>	Overwritten with the solution vector.

PBLAS Level 3 Routines

The PBLAS Level 3 routines perform distributed matrix-matrix operations. [Table "PBLAS Level 3 Routine Groups and Their Data Types"](#) lists the PBLAS Level 3 routine groups and the data types associated with them.

PBLAS Level 3 Routine Groups and Their Data Types

Routine Group	Data Types	Description
p?geadd	s, d, c, z	Distributed matrix-matrix sum of general matrices
p?tradd	s, d, c, z	Distributed matrix-matrix sum of triangular matrices
p?gemm	s, d, c, z	Distributed matrix-matrix product of general matrices
p?hemm	c, z	Distributed matrix-matrix product, one matrix is Hermitian

Routine Group	Data Types	Description
p?herk	c, z	Rank-k update of a distributed Hermitian matrix
p?her2k	c, z	Rank-2k update of a distributed Hermitian matrix
p?symm	s, d, c, z	Matrix-matrix product of distributed symmetric matrices
p?syrk	s, d, c, z	Rank-k update of a distributed symmetric matrix
p?syr2k	s, d, c, z	Rank-2k update of a distributed symmetric matrix
p?tran	s, d	Transposition of a real distributed matrix
p?tranc	c, z	Transposition of a complex distributed matrix (conjugated)
p?tranu	c, z	Transposition of a complex distributed matrix
p?trmm	s, d, c, z	Distributed matrix-matrix product, one matrix is triangular
p?trsm	s, d, c, z	Solution of a distributed matrix equation, one matrix is triangular

p?geadd

Performs sum operation for two distributed general matrices.

Syntax

```
void psgeadd (char *trans , MKL_INT *m , MKL_INT *n , float *alpha , float *a ,
MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *beta , float *c , MKL_INT *ic ,
MKL_INT *jc , MKL_INT *descc );

void pdgeadd (char *trans , MKL_INT *m , MKL_INT *n , double *alpha , double *a ,
MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *beta , double *c , MKL_INT *ic ,
MKL_INT *jc , MKL_INT *descc );

void pcgeadd (char *trans , MKL_INT *m , MKL_INT *n , float *alpha , float *a ,
MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *beta , float *c , MKL_INT *ic ,
MKL_INT *jc , MKL_INT *descc );

void pzgeadd (char *trans , MKL_INT *m , MKL_INT *n , double *alpha , double *a ,
MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *beta , double *c , MKL_INT *ic ,
MKL_INT *jc , MKL_INT *descc );
```

Description

The `p?geadd` routines perform sum operation for two distributed general matrices. The operation is defined as

$$\text{sub}(C) := \text{beta} * \text{sub}(C) + \text{alpha} * \text{op}(\text{sub}(A)),$$

where:

$\text{op}(x)$ is one of $\text{op}(x) = x$, or $\text{op}(x) = x'$,

α and β are scalars,

$\text{sub}(C)$ is an m -by- n distributed matrix, $\text{sub}(C) = C(\text{ic}:\text{ic}+m-1, \text{jc}:\text{jc}+n-1)$.

$\text{sub}(A)$ is a distributed matrix, $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+m-1)$.

Input Parameters

<i>trans</i>	(global) Specifies the operation: if <i>trans</i> = 'N' or 'n', then $\text{op}(\text{sub}(A)) := \text{sub}(A)$; if <i>trans</i> = 'T' or 't', then $\text{op}(\text{sub}(A)) := \text{sub}(A)'$; if <i>trans</i> = 'C' or 'c', then $\text{op}(\text{sub}(A)) := \text{sub}(A)'$.
<i>m</i>	(global) Specifies the number of rows of the distributed matrix $\text{sub}(C)$ and the number of columns of the submatrix $\text{sub}(A)$, $m \geq 0$.
<i>n</i>	(global) Specifies the number of columns of the distributed matrix $\text{sub}(C)$ and the number of rows of the submatrix $\text{sub}(A)$, $n \geq 0$.
<i>alpha</i>	(global) Specifies the scalar <i>alpha</i> .
<i>a</i>	(local) Array, size $(\text{lld\_a}, \text{LOCq}(\text{ja}+m-1))$. This array contains the local pieces of the distributed matrix $\text{sub}(A)$.
<i>ia, ja</i>	(global) The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .
<i>beta</i>	(global) Specifies the scalar <i>beta</i> . When <i>beta</i> is equal to zero, then $\text{sub}(C)$ need not be set on input.
<i>c</i>	(local) Array, size $(\text{lld\_c}, \text{LOCq}(\text{jc}+n-1))$. This array contains the local pieces of the distributed matrix $\text{sub}(C)$.
<i>ic, jc</i>	(global) The row and column indices in the distributed matrix <i>C</i> indicating the first row and the first column of the submatrix $\text{sub}(C)$, respectively.
<i>desc</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>C</i> .

Output Parameters

<i>c</i>	Overwritten by the updated submatrix.

p?tradd

Performs sum operation for two distributed triangular matrices.

Syntax

```
void pstradd (char *uplo , char *trans , MKL_INT *m , MKL_INT *n , float *alpha ,
float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *beta , float *c ,
MKL_INT *ic , MKL_INT *jc , MKL_INT *descc );

void pdtradd (char *uplo , char *trans , MKL_INT *m , MKL_INT *n , double *alpha ,
double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *beta , double *c ,
MKL_INT *ic , MKL_INT *jc , MKL_INT *descc );

void pctradd (char *uplo , char *trans , MKL_INT *m , MKL_INT *n , float *alpha ,
float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *beta , float *c ,
MKL_INT *ic , MKL_INT *jc , MKL_INT *descc );

void pztradd (char *uplo , char *trans , MKL_INT *m , MKL_INT *n , double *alpha ,
double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *beta , double *c ,
MKL_INT *ic , MKL_INT *jc , MKL_INT *descc );
```

Include Files

Description

The `p?tradd` routines perform sum operation for two distributed triangular matrices. The operation is defined as

$$\text{sub}(C) := \text{beta} * \text{sub}(C) + \text{alpha} * \text{op}(\text{sub}(A)),$$

where:

$\text{op}(x)$ is one of $\text{op}(x) = x$, or $\text{op}(x) = x'$, or $\text{op}(x) = \text{conjg}(x')$.

alpha and *beta* are scalars,

sub(C) is an *m*-by-*n* distributed matrix, $\text{sub}(C) = C(\text{ic}:\text{ic}+m-1, \text{jc}:\text{jc}+n-1)$.

sub(A) is a distributed matrix, $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+m-1)$.

Input Parameters

<i>uplo</i>	(global) Specifies whether the distributed matrix <i>sub(C)</i> is upper or lower triangular: if <i>uplo</i> = 'U' or 'u', then the matrix is upper triangular; if <i>uplo</i> = 'L' or 'l', then the matrix is low triangular.
<i>trans</i>	(global) Specifies the operation: if <i>trans</i> = 'N' or 'n', then $\text{op}(\text{sub}(A)) := \text{sub}(A)$; if <i>trans</i> = 'T' or 't', then $\text{op}(\text{sub}(A)) := \text{sub}(A)'$; if <i>trans</i> = 'C' or 'c', then $\text{op}(\text{sub}(A)) := \text{conjg}(\text{sub}(A)')$.
<i>m</i>	(global) Specifies the number of rows of the distributed matrix <i>sub(C)</i> and the number of columns of the submatrix <i>sub(A)</i> , $m \geq 0$.
<i>n</i>	(global) Specifies the number of columns of the distributed matrix <i>sub(C)</i> and the number of rows of the submatrix <i>sub(A)</i> , $n \geq 0$.
<i>alpha</i>	(global)

	Specifies the scalar <i>alpha</i> .
<i>a</i>	(local) Array, size <code>(lld_a, LOCq(ja+m-1))</code> . This array contains the local pieces of the distributed matrix <code>sub(A)</code> .
<i>ia, ja</i>	(global) The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix <code>sub(A)</code> , respectively.
<i>desca</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .
<i>beta</i>	(global) Specifies the scalar <i>beta</i> . When <i>beta</i> is equal to zero, then <code>sub(C)</code> need not be set on input.
<i>c</i>	(local) Array, size <code>(lld_c, LOCq(jc+n-1))</code> . This array contains the local pieces of the distributed matrix <code>sub(C)</code> .
<i>ic, jc</i>	(global) The row and column indices in the distributed matrix <i>C</i> indicating the first row and the first column of the submatrix <code>sub(C)</code> , respectively.
<i>descc</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>C</i> .

Output Parameters

<i>c</i>	Overwritten by the updated submatrix.

p?gemm

Computes a scalar-matrix-matrix product and adds the result to a scalar-matrix product for distributed matrices.

Syntax

```
void psgemm (char *transa , char *transb , MKL_INT *m , MKL_INT *n , MKL_INT *k ,
float *alpha , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *b ,
MKL_INT *ib , MKL_INT *jb , MKL_INT *descb , float *beta , float *c , MKL_INT *ic ,
MKL_INT *jc , MKL_INT *descc );

void pdgemm (char *transa , char *transb , MKL_INT *m , MKL_INT *n , MKL_INT *k ,
double *alpha , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *b ,
MKL_INT *ib , MKL_INT *jb , MKL_INT *descb , double *beta , double *c , MKL_INT *ic ,
MKL_INT *jc , MKL_INT *descc );

void pcgemm (char *transa , char *transb , MKL_INT *m , MKL_INT *n , MKL_INT *k ,
float *alpha , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *b ,
MKL_INT *ib , MKL_INT *jb , MKL_INT *descb , float *beta , float *c , MKL_INT *ic ,
MKL_INT *jc , MKL_INT *descc );
```

```
void pzgemm (char *transa , char *transb , MKL_INT *m , MKL_INT *n , MKL_INT *k ,
double *alpha , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *b ,
MKL_INT *ib , MKL_INT *jb , MKL_INT *descb , double *beta , double *c , MKL_INT *ic ,
MKL_INT *jc , MKL_INT *descc );
```

Include Files

- mkl_pblas.h

Description

The pzgemm routines perform a matrix-matrix operation with general distributed matrices. The operation is defined as

$$\text{sub}(C) := \alpha * \text{op}(\text{sub}(A)) * \text{op}(\text{sub}(B)) + \beta * \text{sub}(C),$$

where:

$\text{op}(x)$ is one of $\text{op}(x) = x$, or $\text{op}(x) = x'$,

α and β are scalars,

$\text{sub}(A)=A(ia:ia+m-1, ja:ja+k-1)$, $\text{sub}(B)=B(ib:ib+k-1, jb:jb+n-1)$, and $\text{sub}(C)=C(ic:ic+m-1, jc:jc+n-1)$, are distributed matrices.

Input Parameters

<i>transa</i>	(global) Specifies the form of $\text{op}(\text{sub}(A))$ used in the matrix multiplication: if <i>transa</i> = 'N' or 'n', then $\text{op}(\text{sub}(A)) = \text{sub}(A)$; if <i>transa</i> = 'T' or 't', then $\text{op}(\text{sub}(A)) = \text{sub}(A)'$; if <i>transa</i> = 'C' or 'c', then $\text{op}(\text{sub}(A)) = \text{sub}(A)'$.
<i>transb</i>	(global) Specifies the form of $\text{op}(\text{sub}(B))$ used in the matrix multiplication: if <i>transb</i> = 'N' or 'n', then $\text{op}(\text{sub}(B)) = \text{sub}(B)$; if <i>transb</i> = 'T' or 't', then $\text{op}(\text{sub}(B)) = \text{sub}(B)'$; if <i>transb</i> = 'C' or 'c', then $\text{op}(\text{sub}(B)) = \text{sub}(B)'$.
<i>m</i>	(global) Specifies the number of rows of the distributed matrices $\text{op}(\text{sub}(A))$ and $\text{sub}(C)$, $m \geq 0$.
<i>n</i>	(global) Specifies the number of columns of the distributed matrices $\text{op}(\text{sub}(B))$ and $\text{sub}(C)$, $n \geq 0$. The value of <i>n</i> must be at least zero.
<i>k</i>	(global) Specifies the number of columns of the distributed matrix $\text{op}(\text{sub}(A))$ and the number of rows of the distributed matrix $\text{op}(\text{sub}(B))$. The value of <i>k</i> must be greater than or equal to 0.
<i>alpha</i>	(global) Specifies the scalar <i>alpha</i> . When <i>alpha</i> is equal to zero, then the local entries of the arrays <i>a</i> and <i>b</i> corresponding to the entries of the submatrices $\text{sub}(A)$ and $\text{sub}(B)$ respectively need not be set on input.

<i>a</i>	(local) Array, size <i>lld_a</i> by <i>kla</i> , where <i>kla</i> is <code>LOCc(ja+k-1)</code> when <i>transa</i> = 'N' or 'n', and is <code>LOCq(ja+m-1)</code> otherwise. Before entry this array must contain the local pieces of the distributed matrix <code>sub(A)</code> .
<i>ia, ja</i>	(global) The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix <code>sub(A)</code> , respectively
<i>desca</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .
<i>b</i>	(local) Array, size <i>lld_b</i> by <i>klb</i> , where <i>klb</i> is <code>LOCc(jb+n-1)</code> when <i>transb</i> = 'N' or 'n', and is <code>LOCq(jb+k-1)</code> otherwise. Before entry this array must contain the local pieces of the distributed matrix <code>sub(B)</code> .
<i>ib, jb</i>	(global) The row and column indices in the distributed matrix <i>B</i> indicating the first row and the first column of the submatrix <code>sub(B)</code> , respectively
<i>descb</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>B</i> .
<i>beta</i>	(global) Specifies the scalar <i>beta</i> . When <i>beta</i> is equal to zero, then <code>sub(C)</code> need not be set on input.
<i>c</i>	(local) Array, size (<i>lld_a</i> , <code>LOCq(jc+n-1)</code>). Before entry this array must contain the local pieces of the distributed matrix <code>sub(C)</code> .
<i>ic, jc</i>	(global) The row and column indices in the distributed matrix <i>C</i> indicating the first row and the first column of the submatrix <code>sub(C)</code> , respectively
<i>descc</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>C</i> .

Output Parameters

<i>c</i>	Overwritten by the <i>m</i> -by- <i>n</i> distributed matrix $\alpha * \text{op}(\text{sub}(A)) * \text{op}(\text{sub}(B)) + \text{beta} * \text{sub}(C)$.

p?hemm

Performs a scalar-matrix-matrix product (one matrix operand is Hermitian) and adds the result to a scalar-matrix product.

Syntax

```
void pchemm (char *side , char *uplo , MKL_INT *m , MKL_INT *n , float *alpha , float
*a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *b , MKL_INT *ib , MKL_INT
*jb , MKL_INT *descb , float *beta , float *c , MKL_INT *ic , MKL_INT *jc , MKL_INT
*descc );
```

```
void pzhemm (char *side , char *uplo , MKL_INT *m , MKL_INT *n , double *alpha ,
double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *b , MKL_INT *ib ,
MKL_INT *jb , MKL_INT *descb , double *beta , double *c , MKL_INT *ic , MKL_INT *jc ,
MKL_INT *descc );
```

Include Files

- mkl_pblas.h

Description

The `pzhemm` routines perform a matrix-matrix operation with distributed matrices. The operation is defined as

```
sub(C) := alpha*sub(A)*sub(B) + beta*sub(C),
```

or

```
sub(C) := alpha*sub(B)*sub(A) + beta*sub(C),
```

where:

alpha and *beta* are scalars,

`sub(A)` is a Hermitian distributed matrix, `sub(A)=A(ia:ia+m-1, ja:ja+m-1)`, if *side* = 'L', and `sub(A)=A(ia:ia+n-1, ja:ja+n-1)`, if *side* = 'R'.

`sub(B)` and `sub(C)` are *m*-by-*n* distributed matrices.

`sub(B)=B(ib:ib+m-1, jb:jb+n-1)`, `sub(C)=C(ic:ic+m-1, jc:jc+n-1)`.

Input Parameters

<i>side</i>	(global) Specifies whether the Hermitian distributed matrix <code>sub(A)</code> appears on the left or right in the operation: if <i>side</i> = 'L' or 'l', then <code>sub(C) := alpha*sub(A) *sub(B) + beta*sub(C)</code> ; if <i>side</i> = 'R' or 'r', then <code>sub(C) := alpha*sub(B) *sub(A) + beta*sub(C)</code> .
<i>uplo</i>	(global) Specifies whether the upper or lower triangular part of the Hermitian distributed matrix <code>sub(A)</code> is used: if <i>uplo</i> = 'U' or 'u', then the upper triangular part is used; if <i>uplo</i> = 'L' or 'l', then the lower triangular part is used.
<i>m</i>	(global) Specifies the number of rows of the distribute submatrix <code>sub(C)</code> , $m \geq 0$.
<i>n</i>	(global) Specifies the number of columns of the distribute submatrix <code>sub(C)</code> , $n \geq 0$.
<i>alpha</i>	(global) Specifies the scalar <i>alpha</i> .
<i>a</i>	(local) Array, size <code>(lld_a, LOCq(ja+na-1))</code> .

Before entry this array must contain the local pieces of the symmetric distributed matrix `sub(A)`, such that when `uplo = 'U' or 'u'`, the `na-by-na` upper triangular part of the distributed matrix `sub(A)` must contain the upper triangular part of the Hermitian distributed matrix and the strictly lower triangular part of `sub(A)` is not referenced, and when `uplo = 'L' or 'l'`, the `na-by-na` lower triangular part of the distributed matrix `sub(A)` must contain the lower triangular part of the Hermitian distributed matrix and the strictly upper triangular part of `sub(A)` is not referenced.

<code>ia, ja</code>	(global) The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix <code>sub(A)</code> , respectively
<code>desca</code>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .
<code>b</code>	(local) Array, size <code>(lld_b, LOCq(jb+n-1))</code> . Before entry this array must contain the local pieces of the distributed matrix <code>sub(B)</code> .
<code>ib, jb</code>	(global) The row and column indices in the distributed matrix <i>B</i> indicating the first row and the first column of the submatrix <code>sub(B)</code> , respectively.
<code>descb</code>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>B</i> .
<code>beta</code>	(global) Specifies the scalar <i>beta</i> . When <i>beta</i> is set to zero, then <code>sub(C)</code> need not be set on input.
<code>c</code>	(local) Array, size <code>(lld_c, LOCq(jc+n-1))</code> . Before entry this array must contain the local pieces of the distributed matrix <code>sub(C)</code> .
<code>ic, jc</code>	(global) The row and column indices in the distributed matrix <i>C</i> indicating the first row and the first column of the submatrix <code>sub(C)</code> , respectively
<code>descc</code>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>C</i> .

Output Parameters

<code>c</code>	Overwritten by the <i>m</i> -by- <i>n</i> updated distributed matrix.

p?herk

Performs a rank-*k* update of a distributed Hermitian matrix.

Syntax

```
void pcherk (char *uplo , char *trans , MKL_INT *n , MKL_INT *k , float *alpha , float
*a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *beta , float *c , MKL_INT
*ic , MKL_INT *jc , MKL_INT *descc );
```

```
void pzherk (char *uplo , char *trans , MKL_INT *n , MKL_INT *k , double *alpha ,
double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *beta , double *c ,
MKL_INT *ic , MKL_INT *jc , MKL_INT *descc );
```

Include Files

- mkl_pblas.h

Description

The pzherk routines perform a distributed matrix-matrix operation defined as

```
sub(C) := alpha*sub(A)*conjg(sub(A)') + beta*sub(C),
```

or

```
sub(C) := alpha*conjg(sub(A)')*sub(A) + beta*sub(C),
```

where:

alpha and *beta* are scalars,

sub(C) is an *n*-by-*n* Hermitian distributed matrix, *sub(C)* = *C*(*ic:ic+n-1*, *jc:jc+n-1*).

sub(A) is a distributed matrix, *sub(A)* = *A*(*ia:ia+n-1*, *ja:ja+k-1*), if *trans* = 'N' or 'n', and *sub(A)* = *A*(*ia:ia+k-1*, *ja:ja+n-1*) otherwise.

Input Parameters

<i>uplo</i>	(global) Specifies whether the upper or lower triangular part of the Hermitian distributed matrix <i>sub(C)</i> is used: If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the <i>sub(C)</i> is used. If <i>uplo</i> = 'L' or 'l', then the low triangular part of the <i>sub(C)</i> is used.
<i>trans</i>	(global) Specifies the operation: if <i>trans</i> = 'N' or 'n', then <i>sub(C)</i> := <i>alpha</i> * <i>sub(A)</i> *conjg(<i>sub(A)'</i>) + <i>beta</i> * <i>sub(C)</i> ; if <i>trans</i> = 'C' or 'c', then <i>sub(C)</i> := <i>alpha</i> *conjg(<i>sub(A)'</i>)* <i>sub(A)</i> + <i>beta</i> * <i>sub(C)</i> .
<i>n</i>	(global) Specifies the order of the distributed matrix <i>sub(C)</i> , $n \geq 0$.
<i>k</i>	(global) On entry with <i>trans</i> = 'N' or 'n', <i>k</i> specifies the number of columns of the distributed matrix <i>sub(A)</i> , and on entry with <i>trans</i> = 'T' or 't' or 'C' or 'c', <i>k</i> specifies the number of rows of the distributed matrix <i>sub(A)</i> , $k \geq 0$.
<i>alpha</i>	(global) Specifies the scalar <i>alpha</i> .
<i>a</i>	(local) Array, size (<i>lld_a</i> , <i>kla</i>), where <i>kla</i> is LOCq(<i>ja+k-1</i>) when <i>trans</i> = 'N' or 'n', and is LOCq(<i>ja+n-1</i>) otherwise. Before entry with <i>trans</i> = 'N' or 'n', this array contains the local pieces of the distributed matrix <i>sub(A)</i> .

<i>ia, ja</i>	(global) The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix <code>sub(A)</code> , respectively.
<i>desca</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .
<i>beta</i>	(global) Specifies the scalar <i>beta</i> .
<i>c</i>	(local) Array, size <code>(lld_c, LOCq(jc+n-1))</code> . Before entry with <i>uplo</i> = 'U' or 'u', this array contains <i>n</i> -by- <i>n</i> upper triangular part of the symmetric distributed matrix <code>sub(C)</code> and its strictly lower triangular part is not referenced. Before entry with <i>uplo</i> = 'L' or 'l', this array contains <i>n</i> -by- <i>n</i> lower triangular part of the symmetric distributed matrix <code>sub(C)</code> and its strictly upper triangular part is not referenced.
<i>ic, jc</i>	(global) The row and column indices in the distributed matrix <i>C</i> indicating the first row and the first column of the submatrix <code>sub(C)</code> , respectively.
<i>descc</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>C</i> .

Output Parameters

<i>c</i>	With <i>uplo</i> = 'U' or 'u', the upper triangular part of <code>sub(C)</code> is overwritten by the upper triangular part of the updated distributed matrix. With <i>uplo</i> = 'L' or 'l', the lower triangular part of <code>sub(C)</code> is overwritten by the upper triangular part of the updated distributed matrix.

p?her2k

Performs a rank-2k update of a Hermitian distributed matrix.

Syntax

```
void pcher2k (char *uplo , char *trans , MKL_INT *n , MKL_INT *k , float *alpha ,
float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *b , MKL_INT *ib ,
MKL_INT *jb , MKL_INT *descb , float *beta , float *c , MKL_INT *ic , MKL_INT *jc ,
MKL_INT *descc );
```

```
void pzher2k (char *uplo , char *trans , MKL_INT *n , MKL_INT *k , double *alpha ,
double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *b , MKL_INT *ib ,
MKL_INT *jb , MKL_INT *descb , double *beta , double *c , MKL_INT *ic , MKL_INT *jc ,
MKL_INT *descc );
```

Include Files

- `mkl_pblas.h`

Description

The `p?her2k` routines perform a distributed matrix-matrix operation defined as

```
sub(C) := alpha*sub(A)*conjg(sub(B)') + conjg(alpha)*sub(B)*conjg(sub(A)') + beta*sub(C),
```

or

```
sub(C) := alpha*conjg(sub(A)')*sub(A) + conjg(alpha)*conjg(sub(B)')*sub(A) + beta*sub(C),
```

where:

alpha and *beta* are scalars,

sub(C) is an *n*-by-*n* Hermitian distributed matrix, *sub(C)* = *C(ic:ic+n-1, jc:jc+n-1)*.

sub(A) is a distributed matrix, *sub(A)* = *A(ia:ia+n-1, ja:ja+k-1)*, if *trans* = 'N' or 'n', and *sub(A)* = *A(ia:ia+k-1, ja:ja+n-1)* otherwise.

sub(B) is a distributed matrix, *sub(B)* = *B(ib:ib+n-1, jb:jb+k-1)*, if *trans* = 'N' or 'n', and *sub(B)* = *B(ib:ib+k-1, jb:jb+n-1)* otherwise.

Input Parameters

<i>uplo</i>	(global) Specifies whether the upper or lower triangular part of the Hermitian distributed matrix <i>sub(C)</i> is used: If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the <i>sub(C)</i> is used. If <i>uplo</i> = 'L' or 'l', then the low triangular part of the <i>sub(C)</i> is used.
<i>trans</i>	(global) Specifies the operation: if <i>trans</i> = 'N' or 'n', then <i>sub(C)</i> := <i>alpha*sub(A)*conjg(sub(B)') + conjg(alpha)*sub(B)*conjg(sub(A)') + beta*sub(C)</i> ; if <i>trans</i> = 'C' or 'c', then <i>sub(C)</i> := <i>alpha*conjg(sub(A)')*sub(A) + conjg(alpha)*conjg(sub(B)')*sub(A) + beta*sub(C)</i> .
<i>n</i>	(global) Specifies the order of the distributed matrix <i>sub(C)</i> , $n \geq 0$.
<i>k</i>	(global) On entry with <i>trans</i> = 'N' or 'n', <i>k</i> specifies the number of columns of the distributed matrices <i>sub(A)</i> and <i>sub(B)</i> , and on entry with <i>trans</i> = 'C' or 'c', <i>k</i> specifies the number of rows of the distributed matrices <i>sub(A)</i> and <i>sub(B)</i> , $k \geq 0$.
<i>alpha</i>	(global) Specifies the scalar <i>alpha</i> .
<i>a</i>	(local) Array, size (<i>lld_a</i> , <i>kla</i>), where <i>kla</i> is <code>LOCq(ja+k-1)</code> when <i>trans</i> = 'N' or 'n', and is <code>LOCq(ja+n-1)</code> otherwise. Before entry with <i>trans</i> = 'N' or 'n', this array contains the local pieces of the distributed matrix <i>sub(A)</i> .
<i>ia, ja</i>	(global) The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix <i>sub(A)</i> , respectively.
<i>desca</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .

<i>b</i>	(local) Array, size (lld_b, klb) , where klb is $LOCq(jb+k-1)$ when $trans = 'N'$ or $'n'$, and is $LOCq(jb+n-1)$ otherwise. Before entry with $trans = 'N'$ or $'n'$, this array contains the local pieces of the distributed matrix $sub(B)$.
<i>ib, jb</i>	(global) The row and column indices in the distributed matrix B indicating the first row and the first column of the submatrix $sub(B)$, respectively.
<i>descb</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix B .
<i>beta</i>	(global) Specifies the scalar <i>beta</i> .
<i>c</i>	(local) Array, size $(lld\_c, LOCq(jc+n-1))$. Before entry with $uplo = 'U'$ or $'u'$, this array contains n -by- n upper triangular part of the symmetric distributed matrix $sub(C)$ and its strictly lower triangular part is not referenced. Before entry with $uplo = 'L'$ or $'l'$, this array contains n -by- n lower triangular part of the symmetric distributed matrix $sub(C)$ and its strictly upper triangular part is not referenced.
<i>ic, jc</i>	(global) The row and column indices in the distributed matrix C indicating the first row and the first column of the submatrix $sub(C)$, respectively.
<i>descc</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix C .

Output Parameters

<i>c</i>	With $uplo = 'U'$ or $'u'$, the upper triangular part of $sub(C)$ is overwritten by the upper triangular part of the updated distributed matrix. With $uplo = 'L'$ or $'l'$, the lower triangular part of $sub(C)$ is overwritten by the upper triangular part of the updated distributed matrix.

p?symm

Performs a scalar-matrix-matrix product (one matrix operand is symmetric) and adds the result to a scalar-matrix product for distribute matrices.

Syntax

```
void pssymm (char *side , char *uplo , MKL_INT *m , MKL_INT *n , float *alpha , float
*a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *b , MKL_INT *ib , MKL_INT
*jb , MKL_INT *descb , float *beta , float *c , MKL_INT *ic , MKL_INT *jc , MKL_INT
*descc );
```

```
void pdsymm (char *side , char *uplo , MKL_INT *m , MKL_INT *n , double *alpha ,
double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *b , MKL_INT *ib ,
MKL_INT *jb , MKL_INT *descb , double *beta , double *c , MKL_INT *ic , MKL_INT *jc ,
MKL_INT *descc );
```

```
void pcsymm (char *side , char *uplo , MKL_INT *m , MKL_INT *n , float *alpha , float
*a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *b , MKL_INT *ib , MKL_INT
*jb , MKL_INT *descb , float *beta , float *c , MKL_INT *ic , MKL_INT *jc , MKL_INT
*descc );
```

```
void pzsymm (char *side , char *uplo , MKL_INT *m , MKL_INT *n , double *alpha ,
double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *b , MKL_INT *ib ,
MKL_INT *jb , MKL_INT *descb , double *beta , double *c , MKL_INT *ic , MKL_INT *jc ,
MKL_INT *descc );
```

Include Files

- mkl_pblas.h

Description

The `p?symm` routines perform a matrix-matrix operation with distributed matrices. The operation is defined as

$$\text{sub}(C) := \alpha \text{sub}(A) * \text{sub}(B) + \beta \text{sub}(C),$$

or

$$\text{sub}(C) := \alpha \text{sub}(B) * \text{sub}(A) + \beta \text{sub}(C),$$

where:

alpha and *beta* are scalars,

sub(A) is a symmetric distributed matrix, *sub(A)* = *A*(*ia:ia+m-1*, *ja:ja+m-1*), if *side* = 'L', and
sub(A) = *A*(*ia:ia+n-1*, *ja:ja+n-1*), if *side* = 'R'.

sub(B) and *sub(C)* are *m*-by-*n* distributed matrices.

sub(B) = *B*(*ib:ib+m-1*, *jb:jb+n-1*), *sub(C)* = *C*(*ic:ic+m-1*, *jc:jc+n-1*).

Input Parameters

<i>side</i>	(global) Specifies whether the symmetric distributed matrix <i>sub(A)</i> appears on the left or right in the operation: if <i>side</i> = 'L' or 'l', then $\text{sub}(C) := \alpha \text{sub}(A) * \text{sub}(B) + \beta \text{sub}(C)$; if <i>side</i> = 'R' or 'r', then $\text{sub}(C) := \alpha \text{sub}(B) * \text{sub}(A) + \beta \text{sub}(C)$.
<i>uplo</i>	(global) Specifies whether the upper or lower triangular part of the symmetric distributed matrix <i>sub(A)</i> is used: if <i>uplo</i> = 'U' or 'u', then the upper triangular part is used; if <i>uplo</i> = 'L' or 'l', then the lower triangular part is used.
<i>m</i>	(global) Specifies the number of rows of the distribute submatrix <i>sub(C)</i> , $m \geq 0$.
<i>n</i>	(global) Specifies the number of columns of the distribute submatrix <i>sub(C)</i> , $n \geq 0$.
<i>alpha</i>	(global) Specifies the scalar <i>alpha</i> .
<i>a</i>	(local)

Array, size $(lld\_a, LOCq(ja+na-1))$.

Before entry this array must contain the local pieces of the symmetric distributed matrix $sub(A)$, such that when $uplo = 'U'$ or $'u'$, the na -by- na upper triangular part of the distributed matrix $sub(A)$ must contain the upper triangular part of the symmetric distributed matrix and the strictly lower triangular part of $sub(A)$ is not referenced, and when $uplo = 'L'$ or $'l'$, the na -by- na lower triangular part of the distributed matrix $sub(A)$ must contain the lower triangular part of the symmetric distributed matrix and the strictly upper triangular part of $sub(A)$ is not referenced.

ia, ja

(global) The row and column indices in the distributed matrix A indicating the first row and the first column of the submatrix $sub(A)$, respectively.

desca

(global and local) array of dimension 9. The array descriptor of the distributed matrix A .

b

(local)

Array, size $(lld\_b, LOCq(jb+n-1))$. Before entry this array must contain the local pieces of the distributed matrix $sub(B)$.

ib, jb

(global) The row and column indices in the distributed matrix B indicating the first row and the first column of the submatrix $sub(B)$, respectively.

descb

(global and local) array of dimension 9. The array descriptor of the distributed matrix B .

beta

(global)

Specifies the scalar *beta*.

When *beta* is set to zero, then $sub(C)$ need not be set on input.

c

(local)

Array, size $(lld\_c, LOCq(jc+n-1))$. Before entry this array must contain the local pieces of the distributed matrix $sub(C)$.

ic, jc

(global) The row and column indices in the distributed matrix C indicating the first row and the first column of the submatrix $sub(C)$, respectively.

desc

(global and local) array of dimension 9. The array descriptor of the distributed matrix C .

Output Parameters

c

Overwritten by the m -by- n updated matrix.

p?syk

Performs a rank- k update of a symmetric distributed matrix.

Syntax

```
void pssyrk (char *uplo , char *trans , MKL_INT *n , MKL_INT *k , float *alpha , float
*a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *beta , float *c , MKL_INT
*ic , MKL_INT *jc , MKL_INT *descc );
```

```
void pdsyrk (char *uplo , char *trans , MKL_INT *n , MKL_INT *k , double *alpha ,
double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *beta , double *c ,
MKL_INT *ic , MKL_INT *jc , MKL_INT *descc );
```

```
void pcsyrk (char *uplo , char *trans , MKL_INT *n , MKL_INT *k , float *alpha , float
*a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *beta , float *c , MKL_INT
*ic , MKL_INT *jc , MKL_INT *descc );
```

```
void pzsyrk (char *uplo , char *trans , MKL_INT *n , MKL_INT *k , double *alpha ,
double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *beta , double *c ,
MKL_INT *ic , MKL_INT *jc , MKL_INT *descc );
```

Include Files

- mkl_pblas.h

Description

The p?syrk routines perform a distributed matrix-matrix operation defined as

$$\text{sub}(C) := \alpha * \text{sub}(A) * \text{sub}(A)^T + \beta * \text{sub}(C),$$

or

$$\text{sub}(C) := \alpha * \text{sub}(A)^T * \text{sub}(A) + \beta * \text{sub}(C),$$

where:

alpha and *beta* are scalars,

sub(C) is an *n*-by-*n* symmetric distributed matrix, $\text{sub}(C) = C(\text{ic}:\text{ic}+n-1, \text{jc}:\text{jc}+n-1)$.

sub(A) is a distributed matrix, $\text{sub}(A) = A(\text{ia}:\text{ia}+n-1, \text{ja}:\text{ja}+k-1)$, if *trans* = 'N' or 'n', and $\text{sub}(A) = A(\text{ia}:\text{ia}+k-1, \text{ja}:\text{ja}+n-1)$ otherwise.

Input Parameters

<i>uplo</i>	(global) Specifies whether the upper or lower triangular part of the symmetric distributed matrix <i>sub(C)</i> is used: If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the <i>sub(C)</i> is used. If <i>uplo</i> = 'L' or 'l', then the low triangular part of the <i>sub(C)</i> is used.
<i>trans</i>	(global) Specifies the operation: if <i>trans</i> = 'N' or 'n', then $\text{sub}(C) := \alpha * \text{sub}(A) * \text{sub}(A)^T + \beta * \text{sub}(C)$; if <i>trans</i> = 'T' or 't', then $\text{sub}(C) := \alpha * \text{sub}(A)^T * \text{sub}(A) + \beta * \text{sub}(C)$.
<i>n</i>	(global) Specifies the order of the distributed matrix <i>sub(C)</i> , $n \geq 0$.

<i>k</i>	(global) On entry with <i>trans</i> = 'N' or 'n', <i>k</i> specifies the number of columns of the distributed matrix $\text{sub}(A)$, and on entry with <i>trans</i> = 'T' or 't', <i>k</i> specifies the number of rows of the distributed matrix $\text{sub}(A)$, $k \geq 0$.
<i>alpha</i>	(global) Specifies the scalar <i>alpha</i> .
<i>a</i>	(local) Array, size (<i>lld_a</i> , <i>kla</i>), where <i>kla</i> is $\text{LOCq}(ja+k-1)$ when <i>trans</i> = 'N' or 'n', and is $\text{LOCq}(ja+n-1)$ otherwise. Before entry with <i>trans</i> = 'N' or 'n', this array contains the local pieces of the distributed matrix $\text{sub}(A)$.
<i>ia, ja</i>	(global) The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .
<i>beta</i>	(global) Specifies the scalar <i>beta</i> .
<i>c</i>	(local) Array, size (<i>lld_c</i> , $\text{LOCq}(jc+n-1)$). Before entry with <i>uplo</i> = 'U' or 'u', this array contains <i>n</i> -by- <i>n</i> upper triangular part of the symmetric distributed matrix $\text{sub}(C)$ and its strictly lower triangular part is not referenced. Before entry with <i>uplo</i> = 'L' or 'l', this array contains <i>n</i> -by- <i>n</i> lower triangular part of the symmetric distributed matrix $\text{sub}(C)$ and its strictly upper triangular part is not referenced.
<i>ic, jc</i>	(global) The row and column indices in the distributed matrix <i>C</i> indicating the first row and the first column of the submatrix $\text{sub}(C)$, respectively.
<i>desc</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>C</i> .

Output Parameters

<i>c</i>	With <i>uplo</i> = 'U' or 'u', the upper triangular part of $\text{sub}(C)$ is overwritten by the upper triangular part of the updated distributed matrix. With <i>uplo</i> = 'L' or 'l', the lower triangular part of $\text{sub}(C)$ is overwritten by the upper triangular part of the updated distributed matrix.

p?sy2k

Performs a rank-2*k* update of a symmetric distributed matrix.

Syntax

```
void pssyr2k (char *uplo , char *trans , MKL_INT *n , MKL_INT *k , float *alpha ,
float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *b , MKL_INT *ib ,
MKL_INT *jb , MKL_INT *descb , float *beta , float *c , MKL_INT *ic , MKL_INT *jc ,
MKL_INT *descc );
```

```
void pdsyr2k (char *uplo , char *trans , MKL_INT *n , MKL_INT *k , double *alpha ,
double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *b , MKL_INT *ib ,
MKL_INT *jb , MKL_INT *descb , double *beta , double *c , MKL_INT *ic , MKL_INT *jc ,
MKL_INT *descc );
```

```
void pcsyr2k (char *uplo , char *trans , MKL_INT *n , MKL_INT *k , float *alpha ,
float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , float *b , MKL_INT *ib ,
MKL_INT *jb , MKL_INT *descb , float *beta , float *c , MKL_INT *ic , MKL_INT *jc ,
MKL_INT *descc );
```

void pzsyr2k (char *uplo , char *trans , MKL_INT *n , MKL_INT *k , double *alpha ,
double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca , double *b , MKL_INT *ib ,
MKL_INT *jb , MKL_INT *descb , double *beta , double *c , MKL_INT *ic , MKL_INT *jc ,
MKL_INT *descc );
```

Include Files

- mkl_pblas.h

Description

The p?syr2k routines perform a distributed matrix-matrix operation defined as

$$\text{sub}(C) := \alpha * \text{sub}(A) * \text{sub}(B)' + \alpha * \text{sub}(B) * \text{sub}(A)' + \beta * \text{sub}(C),$$

or

$$\text{sub}(C) := \alpha * \text{sub}(A)' * \text{sub}(B) + \alpha * \text{sub}(B)' * \text{sub}(A) + \beta * \text{sub}(C),$$

where:

alpha and *beta* are scalars,

sub(C) is an *n*-by-*n* symmetric distributed matrix, $\text{sub}(C) = C(ic:ic+n-1, jc:jc+n-1)$.

sub(A) is a distributed matrix, $\text{sub}(A) = A(ia:ia+n-1, ja:ja+k-1)$, if *trans* = 'N' or 'n', and $\text{sub}(A) = A(ia:ia+k-1, ja:ja+n-1)$ otherwise.

sub(B) is a distributed matrix, $\text{sub}(B) = B(ib:ib+n-1, jb:jb+k-1)$, if *trans* = 'N' or 'n', and $\text{sub}(B) = B(ib:ib+k-1, jb:jb+n-1)$ otherwise.

Input Parameters

<i>uplo</i>	(global) Specifies whether the upper or lower triangular part of the symmetric distributed matrix <i>sub(C)</i> is used: If <i>uplo</i> = 'U' or 'u', then the upper triangular part of the <i>sub(C)</i> is used. If <i>uplo</i> = 'L' or 'l', then the low triangular part of the <i>sub(C)</i> is used.
<i>trans</i>	(global) Specifies the operation: if <i>trans</i> = 'N' or 'n', then $\text{sub}(C) := \alpha * \text{sub}(A) * \text{sub}(B)' + \alpha * \text{sub}(B) * \text{sub}(A)' + \beta * \text{sub}(C);$

if $trans = 'T'$ or $'t'$, then $sub(C) := alpha * sub(B) * sub(A) + alpha * sub(A) * sub(B) + beta * sub(C)$.

n	(global) Specifies the order of the distributed matrix $sub(C)$, $n \geq 0$.
k	(global) On entry with $trans = 'N'$ or $'n'$, k specifies the number of columns of the distributed matrices $sub(A)$ and $sub(B)$, and on entry with $trans = 'T'$ or $'t'$, k specifies the number of rows of the distributed matrices $sub(A)$ and $sub(B)$, $k \geq 0$.
$alpha$	(global) Specifies the scalar $alpha$.
a	(local) Array, size (lld_a, kla) , where kla is $LOCq(ja+k-1)$ when $trans = 'N'$ or $'n'$, and is $LOCq(ja+n-1)$ otherwise. Before entry with $trans = 'N'$ or $'n'$, this array contains the local pieces of the distributed matrix $sub(A)$.
ia, ja	(global) The row and column indices in the distributed matrix A indicating the first row and the first column of the submatrix $sub(A)$, respectively.
$desca$	(global and local) array of dimension 9. The array descriptor of the distributed matrix A .
b	(local) Array, size (lld_b, klb) , where klb is $LOCq(jb+k-1)$ when $trans = 'N'$ or $'n'$, and is $LOCq(jb+n-1)$ otherwise. Before entry with $trans = 'N'$ or $'n'$, this array contains the local pieces of the distributed matrix $sub(B)$.
ib, jb	(global) The row and column indices in the distributed matrix B indicating the first row and the first column of the submatrix $sub(B)$, respectively.
$descb$	(global and local) array of dimension 9. The array descriptor of the distributed matrix B .
$beta$	(global) Specifies the scalar $beta$.
c	(local) Array, size $(lld\_c, LOCq(jc+n-1))$. Before entry with $uplo = 'U'$ or $'u'$, this array contains n -by- n upper triangular part of the symmetric distributed matrix $sub(C)$ and its strictly lower triangular part is not referenced. Before entry with $uplo = 'L'$ or $'l'$, this array contains n -by- n lower triangular part of the symmetric distributed matrix $sub(C)$ and its strictly upper triangular part is not referenced.
ic, jc	(global) The row and column indices in the distributed matrix C indicating the first row and the first column of the submatrix $sub(C)$, respectively.
$descc$	(global and local) array of dimension 9. The array descriptor of the distributed matrix C .

Output Parameters

c With *uplo* = 'U' or 'u', the upper triangular part of *sub(C)* is overwritten by the upper triangular part of the updated distributed matrix.

With *uplo* = 'L' or 'l', the lower triangular part of *sub(C)* is overwritten by the upper triangular part of the updated distributed matrix.

p?tran

Transposes a real distributed matrix.

Syntax

```
void pstran (MKL_INT *m , MKL_INT *n , float *alpha , float *a , MKL_INT *ia , MKL_INT
*ja , MKL_INT *desca , float *beta , float *c , MKL_INT *ic , MKL_INT *jc , MKL_INT
*descc );
```

```
void pdtran (MKL_INT *m , MKL_INT *n , double *alpha , double *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , double *beta , double *c , MKL_INT *ic , MKL_INT *jc ,
MKL_INT *descc );
```

Include Files

- mkl_pblas.h

Description

The p?tran routines transpose a real distributed matrix. The operation is defined as

$$\text{sub}(C) := \text{beta} * \text{sub}(C) + \text{alpha} * \text{sub}(A)^T,$$

where:

alpha and *beta* are scalars,

sub(C) is an *m*-by-*n* distributed matrix, $\text{sub}(C) = C(ic:ic+m-1, jc:jc+n-1)$.

sub(A) is a distributed matrix, $\text{sub}(A) = A(ia:ia+n-1, ja:ja+m-1)$.

Input Parameters

m (global) Specifies the number of rows of the distributed matrix *sub(C)*, $m \geq 0$.

n (global) Specifies the number of columns of the distributed matrix *sub(C)*, $n \geq 0$.

alpha (global)
Specifies the scalar *alpha*.

a (local)
Array, size $(lld\_a, LOCq(ja+m-1))$. This array contains the local pieces of the distributed matrix *sub(A)*.

ia, ja (global) The row and column indices in the distributed matrix *A* indicating the first row and the first column of the submatrix *sub(A)*, respectively.

<i>desca</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .
<i>beta</i>	(global) Specifies the scalar <i>beta</i> . When <i>beta</i> is equal to zero, then <code>sub(C)</code> need not be set on input.
<i>c</i>	(local) Array, size <code>(lld_c, LOCq(jc+n-1))</code> . This array contains the local pieces of the distributed matrix <code>sub(C)</code> .
<i>ic, jc</i>	(global) The row and column indices in the distributed matrix <i>C</i> indicating the first row and the first column of the submatrix <code>sub(C)</code> , respectively.
<i>descc</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>C</i> .

Output Parameters

<i>c</i>	Overwritten by the updated submatrix.

p?tranu

Transposes a distributed complex matrix.

Syntax

```
void pctransu (MKL_INT *m , MKL_INT *n , float *alpha , float *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , float *beta , float *c , MKL_INT *ic , MKL_INT *jc ,
MKL_INT *descc );

void pztransu (MKL_INT *m , MKL_INT *n , double *alpha , double *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , double *beta , double *c , MKL_INT *ic , MKL_INT *jc ,
MKL_INT *descc );
```

Include Files

- `mkl_pblas.h`

Description

The `p?tranu` routines transpose a complex distributed matrix. The operation is defined as

$$\text{sub}(C) := \text{beta} * \text{sub}(C) + \text{alpha} * \text{sub}(A)^T,$$

where:

alpha and *beta* are scalars,

`sub(C)` is an *m*-by-*n* distributed matrix, `sub(C) = C(ic:ic+m-1, jc:jc+n-1)`.

`sub(A)` is a distributed matrix, `sub(A) = A(ia:ia+n-1, ja:ja+m-1)`.

Input Parameters

<i>m</i>	(global) Specifies the number of rows of the distributed matrix <code>sub(C)</code> , $m \geq 0$.

<i>n</i>	(global) Specifies the number of columns of the distributed matrix $\text{sub}(C)$, $n \geq 0$.
<i>alpha</i>	(global) Specifies the scalar <i>alpha</i> .
<i>a</i>	(local) Array, size $(l1d\_a, \text{LOCq}(ja+m-1))$. This array contains the local pieces of the distributed matrix $\text{sub}(A)$.
<i>ia, ja</i>	(global) The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .
<i>beta</i>	(global) Specifies the scalar <i>beta</i> . When <i>beta</i> is equal to zero, then $\text{sub}(C)$ need not be set on input.
<i>c</i>	(local) Array, size $(l1d\_c, \text{LOCq}(jc+n-1))$. This array contains the local pieces of the distributed matrix $\text{sub}(C)$.
<i>ic, jc</i>	(global) The row and column indices in the distributed matrix <i>C</i> indicating the first row and the first column of the submatrix $\text{sub}(C)$, respectively.
<i>descc</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>C</i> .

Output Parameters

<i>c</i>	Overwritten by the updated submatrix.

p?tranc

Transposes a complex distributed matrix, conjugated.

Syntax

```
void pctranc (MKL_INT *m , MKL_INT *n , float *alpha , float *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , float *beta , float *c , MKL_INT *ic , MKL_INT *jc ,
MKL_INT *descc );

void pztranc (MKL_INT *m , MKL_INT *n , double *alpha , double *a , MKL_INT *ia ,
MKL_INT *ja , MKL_INT *desca , double *beta , double *c , MKL_INT *ic , MKL_INT *jc ,
MKL_INT *descc );
```

Include Files

- mkl_pblas.h

Description

The `p?tranc` routines transpose a complex distributed matrix. The operation is defined as

```
sub(C) := beta*sub(C) + alpha*conjg(sub(A)'),
```

where:

alpha and *beta* are scalars,

sub(C) is an *m*-by-*n* distributed matrix, *sub(C)*=*C*(*ic:ic+m-1*, *jc:jc+n-1*).

sub(A) is a distributed matrix, *sub(A)*=*A*(*ia:ia+n-1*, *ja:ja+m-1*).

Input Parameters

<i>m</i>	(global) Specifies the number of rows of the distributed matrix <i>sub(C)</i> , $m \geq 0$.
<i>n</i>	(global) Specifies the number of columns of the distributed matrix <i>sub(C)</i> , $n \geq 0$.
<i>alpha</i>	(global) Specifies the scalar <i>alpha</i> .
<i>a</i>	(local) Array, size (<i>lld_a</i> , <i>LOCq(ja+m-1)</i>). This array contains the local pieces of the distributed matrix <i>sub(A)</i> .
<i>ia, ja</i>	(global) The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix <i>sub(A)</i> , respectively.
<i>desca</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .
<i>beta</i>	(global) Specifies the scalar <i>beta</i> . When <i>beta</i> is equal to zero, then <i>sub(C)</i> need not be set on input.
<i>c</i>	(local) Array, size (<i>lld_c</i> , <i>LOCq(jc+n-1)</i>). This array contains the local pieces of the distributed matrix <i>sub(C)</i> .
<i>ic, jc</i>	(global) The row and column indices in the distributed matrix <i>C</i> indicating the first row and the first column of the submatrix <i>sub(C)</i> , respectively.
<i>desc</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>C</i> .

Output Parameters

<i>c</i>	Overwritten by the updated submatrix.

p?trmm

Computes a scalar-matrix-matrix product (one matrix operand is triangular) for distributed matrices.

Syntax

```
void pstrmm (char *side , char *uplo , char *transa , char *diag , MKL_INT *m ,
MKL_INT *n , float *alpha , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca ,
float *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb );

void pdtrmm (char *side , char *uplo , char *transa , char *diag , MKL_INT *m ,
MKL_INT *n , double *alpha , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca ,
double *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb );

void pctrmm (char *side , char *uplo , char *transa , char *diag , MKL_INT *m ,
MKL_INT *n , float *alpha , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca ,
float *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb );

void pztrmm (char *side , char *uplo , char *transa , char *diag , MKL_INT *m ,
MKL_INT *n , double *alpha , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca ,
double *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb );
```

Include Files

- mkl_pblas.h

Description

The p?trmm routines perform a matrix-matrix operation using triangular matrices. The operation is defined as

```
sub(B) := alpha*op(sub(A))*sub(B)
```

or

```
sub(B) := alpha*sub(B)*op(sub(A))
```

where:

alpha is a scalar,

sub(B) is an *m*-by-*n* distributed matrix, *sub(B)*=*B(ib:ib+m-1, jb:jb+n-1)*.

A is a unit, or non-unit, upper or lower triangular distributed matrix, *sub(A)*=*A(ia:ia+m-1, ja:ja+m-1)*, if *side* = 'L' or 'l', and *sub(A)*=*A(ia:ia+n-1, ja:ja+n-1)*, if *side* = 'R' or 'r'.

op(sub(A)) is one of *op(sub(A))* = *sub(A)*, or *op(sub(A))* = *sub(A)'*, or *op(sub(A))* = *conjg(sub(A)')*.

Input Parameters

<i>side</i>	(global) Specifies whether <i>op(sub(A))</i> appears on the left or right of <i>sub(B)</i> in the operation: if <i>side</i> = 'L' or 'l', then <i>sub(B) := alpha*op(sub(A))*sub(B)</i> ; if <i>side</i> = 'R' or 'r', then <i>sub(B) := alpha*sub(B)*op(sub(A))</i> .
<i>uplo</i>	(global) Specifies whether the distributed matrix <i>sub(A)</i> is upper or lower triangular: if <i>uplo</i> = 'U' or 'u', then the matrix is upper triangular;

	if <i>uplo</i> = 'L' or 'l', then the matrix is low triangular.
<i>transa</i>	(global) Specifies the form of $\text{op}(\text{sub}(A))$ used in the matrix multiplication: if <i>transa</i> = 'N' or 'n', then $\text{op}(\text{sub}(A)) = \text{sub}(A)$; if <i>transa</i> = 'T' or 't', then $\text{op}(\text{sub}(A)) = \text{sub}(A)^T$; if <i>transa</i> = 'C' or 'c', then $\text{op}(\text{sub}(A)) = \text{conjg}(\text{sub}(A))$.
<i>diag</i>	(global) Specifies whether the matrix $\text{sub}(A)$ is unit triangular: if <i>diag</i> = 'U' or 'u' then the matrix is unit triangular; if <i>diag</i> = 'N' or 'n', then the matrix is not unit triangular.
<i>m</i>	(global) Specifies the number of rows of the distributed matrix $\text{sub}(B)$, $m \geq 0$.
<i>n</i>	(global) Specifies the number of columns of the distributed matrix $\text{sub}(B)$, $n \geq 0$.
<i>alpha</i>	(global) Specifies the scalar <i>alpha</i>. When <i>alpha</i> is zero, then the array <i>b</i> need not be set before entry.
<i>a</i>	(local) Array, size <i>lld_a</i> by <i>ka</i>, where <i>ka</i> is at least $\text{LOCq}(1, ja+m-1)$ when <i>side</i> = 'L' or 'l' and is at least $\text{LOCq}(1, ja+n-1)$ when <i>side</i> = 'R' or 'r'. Before entry with <i>uplo</i> = 'U' or 'u', this array contains the local entries corresponding to the entries of the upper triangular distributed matrix $\text{sub}(A)$, and the local entries corresponding to the entries of the strictly lower triangular part of the distributed matrix $\text{sub}(A)$ is not referenced. Before entry with <i>uplo</i> = 'L' or 'l', this array contains the local entries corresponding to the entries of the lower triangular distributed matrix $\text{sub}(A)$, and the local entries corresponding to the entries of the strictly upper triangular part of the distributed matrix $\text{sub}(A)$ is not referenced . When <i>diag</i> = 'U' or 'u', the local entries corresponding to the diagonal elements of the submatrix $\text{sub}(A)$ are not referenced either, but are assumed to be unity.
<i>ia, ja</i>	(global) The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix $\text{sub}(A)$, respectively.
<i>desca</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>A</i> .
<i>b</i>	(local) Array, size (<i>lld_b</i>, $\text{LOCq}(1, jb+n-1)$). Before entry, this array contains the local pieces of the distributed matrix $\text{sub}(B)$.
<i>ib, jb</i>	(global) The row and column indices in the distributed matrix <i>B</i> indicating the first row and the first column of the submatrix $\text{sub}(B)$, respectively.

descb (global and local) array of dimension 9. The array descriptor of the distributed matrix *B*.

Output Parameters

b Overwritten by the transformed distributed matrix.

p?trsm

Solves a distributed matrix equation (one matrix operand is triangular).

Syntax

```
void pstrsm (char *side , char *uplo , char *transa , char *diag , MKL_INT *m ,
MKL_INT *n , float *alpha , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca ,
float *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb );

void pdtrsm (char *side , char *uplo , char *transa , char *diag , MKL_INT *m ,
MKL_INT *n , double *alpha , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca ,
double *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb );

void pctrsm (char *side , char *uplo , char *transa , char *diag , MKL_INT *m ,
MKL_INT *n , float *alpha , float *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca ,
float *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb );

void pztrsm (char *side , char *uplo , char *transa , char *diag , MKL_INT *m ,
MKL_INT *n , double *alpha , double *a , MKL_INT *ia , MKL_INT *ja , MKL_INT *desca ,
double *b , MKL_INT *ib , MKL_INT *jb , MKL_INT *descb );
```

Include Files

- mkl_pblas.h

Description

The p?trsm routines solve one of the following distributed matrix equations:

$\text{op}(\text{sub}(A)) * X = \alpha * \text{sub}(B),$

or

$X * \text{op}(\text{sub}(A)) = \alpha * \text{sub}(B),$

where:

alpha is a scalar,

X and *sub(B)* are *m*-by-*n* distributed matrices, $\text{sub}(B) = B(ib:ib+m-1, jb:jb+n-1);$

A is a unit, or non-unit, upper or lower triangular distributed matrix, $\text{sub}(A) = A(ia:ia+m-1, ja:ja+m-1),$ if *side* = 'L' or 'l', and $\text{sub}(A) = A(ia:ia+n-1, ja:ja+n-1),$ if *side* = 'R' or 'r';

op(sub(A)) is one of *op(sub(A)) = sub(A)*, or *op(sub(A)) = sub(A)'*, or *op(sub(A)) = conjg(sub(A)')*.

The distributed matrix *sub(B)* is overwritten by the solution matrix *X*.

Input Parameters

side (global) Specifies whether *op(sub(A))* appears on the left or right of *X* in the equation:

	if $side = 'L'$ or $'l'$, then $op(sub(A)) * X = alpha * sub(B)$; if $side = 'R'$ or $'r'$, then $X * op(sub(A)) = alpha * sub(B)$.
<i>uplo</i>	(global) Specifies whether the distributed matrix $sub(A)$ is upper or lower triangular: if $uplo = 'U'$ or $'u'$, then the matrix is upper triangular; if $uplo = 'L'$ or $'l'$, then the matrix is low triangular.
<i>transa</i>	(global) Specifies the form of $op(sub(A))$ used in the matrix equation: if $transa = 'N'$ or $'n'$, then $op(sub(A)) = sub(A)$; if $transa = 'T'$ or $'t'$, then $op(sub(A)) = sub(A)'$; if $transa = 'C'$ or $'c'$, then $op(sub(A)) = conjg(sub(A))$.
<i>diag</i>	(global) Specifies whether the matrix $sub(A)$ is unit triangular: if $diag = 'U'$ or $'u'$ then the matrix is unit triangular; if $diag = 'N'$ or $'n'$, then the matrix is not unit triangular.
<i>m</i>	(global) Specifies the number of rows of the distributed matrix $sub(B)$, $m \geq 0$.
<i>n</i>	(global) Specifies the number of columns of the distributed matrix $sub(B)$, $n \geq 0$.
<i>alpha</i>	(global) Specifies the scalar <i>alpha</i>. When <i>alpha</i> is zero, then <i>a</i> is not referenced and <i>b</i> need not be set before entry.
<i>a</i>	(local) Array, size <i>lld_a</i> by <i>ka</i>, where <i>ka</i> is at least $LOCq(1, ja+m-1)$ when $side = 'L'$ or $'l'$ and is at least $LOCq(1, ja+n-1)$ when $side = 'R'$ or $'r'$. Before entry with $uplo = 'U'$ or $'u'$, this array contains the local entries corresponding to the entries of the upper triangular distributed matrix $sub(A)$, and the local entries corresponding to the entries of the strictly lower triangular part of the distributed matrix $sub(A)$ is not referenced. Before entry with $uplo = 'L'$ or $'l'$, this array contains the local entries corresponding to the entries of the lower triangular distributed matrix $sub(A)$, and the local entries corresponding to the entries of the strictly upper triangular part of the distributed matrix $sub(A)$ is not referenced . When $diag = 'U'$ or $'u'$, the local entries corresponding to the diagonal elements of the submatrix $sub(A)$ are not referenced either, but are assumed to be unity.
<i>ia, ja</i>	(global) The row and column indices in the distributed matrix <i>A</i> indicating the first row and the first column of the submatrix $sub(A)$, respectively.
<i>desca</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix <i>A</i>.

<i>b</i>	(local) Array, size ($\text{lld\_b}, \text{LOCq}(1, \text{jb}+n-1)$). Before entry, this array contains the local pieces of the distributed matrix $\text{sub}(B)$.
<i>ib, jb</i>	(global) The row and column indices in the distributed matrix B indicating the first row and the first column of the submatrix $\text{sub}(B)$, respectively.
<i>descb</i>	(global and local) array of dimension 9. The array descriptor of the distributed matrix B .

Output Parameters

<i>b</i>	Overwritten by the solution distributed matrix X .

Partial Differential Equations Support

12

The Intel® Math Kernel Library (Intel® MKL) provides tools for solving Partial Differential Equations (PDE). These tools are Trigonometric Transform interface routines (see [Trigonometric Transform Routines](#)) and Poisson Solver (see [Fast Poisson Solver Routines](#)).

Poisson Solver is designed for fast solving of simple Helmholtz, Poisson, and Laplace problems. The solver is based on the Trigonometric Transform interface, which is, in turn, based on the Intel MKL Fast Fourier Transform (FFT) interface (refer to [Fourier Transform Functions](#)), optimized for Intel® processors.

Direct use of the Trigonometric Transform routines may be helpful to those who have already implemented their own solvers similar to the Intel MKL Poisson Solver. As it may be hard enough to modify the original code so as to make it work with Poisson Solver, you are encouraged to use fast (staggered) sine/cosine transforms implemented in the Trigonometric Transform interface to improve performance of your solver.

Both Trigonometric Transform and Poisson Solver routines can be called from C and Fortran.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Trigonometric Transform Routines

In addition to the Fast Fourier Transform (FFT) interface, described in chapter "[Fast Fourier Transforms](#)", Intel® MKL supports the Real Discrete Trigonometric Transforms (sometimes called real-to-real Discrete Fourier Transforms) interface. In this manual, the interface is referred to as TT interface. It implements a group of routines (TT routines) used to compute sine/cosine, staggered sine/cosine, and twice staggered sine/cosine transforms (referred to as staggered2 sine/cosine transforms, for brevity). The TT interface provides much flexibility of use: you can adjust routines to your particular needs at the cost of manual tuning routine parameters or just call routines with default parameter values. The current Intel MKL implementation of the TT interface can be used in solving partial differential equations and contains routines that are helpful for Fast Poisson and similar solvers.

For the list of Trigonometric Transforms currently implemented in Intel MKL TT interface, see [Transforms Implemented](#).

If you have got used to the FFTW interface (www.fftw.org), you can call the TT interface functions through real-to-real FFTW to Intel MKL wrappers without changing FFTW function calls in your code (refer to [FFTW to Intel® MKL Wrappers for FFTW 3.x](#) for details). However, you are strongly encouraged to use the native TT interface for better performance. Another reason why you should use the wrappers cautiously is that TT and the real-to-real FFTW interfaces are not fully compatible and some features of the real-to-real FFTW, such as strides and multidimensional transforms, are not available through wrappers.

Transforms Implemented

TT routines allow computing the following transforms:

Forward sine transform

$$F(k) = \frac{2}{n} \sum_{i=1}^{n-1} f(i) \sin \frac{ki\pi}{n}, \quad k = 1, \dots, n-1$$

Backward sine transform

$$f(i) = \sum_{k=1}^{n-1} F(k) \sin \frac{ki\pi}{n}, \quad i = 1, \dots, n-1$$

Forward staggered sine transform

$$F(k) = \frac{1}{n} \sin \frac{(2k-1)\pi}{2} f(n) + \frac{2}{n} \sum_{i=1}^{n-1} f(i) \sin \frac{(2k-1)i\pi}{2n}, \quad k = 1, \dots, n$$

Backward staggered sine transform

$$f(i) = \sum_{k=1}^n F(k) \sin \frac{(2k-1)i\pi}{2n}, \quad i = 1, \dots, n$$

Forward staggered2 sine transform

$$F(k) = \frac{2}{n} \sum_{i=1}^n f(i) \sin \frac{(2k-1)(2i-1)\pi}{4n}, \quad k = 1, \dots, n$$

Backward staggered2 sine transform

$$f(i) = \sum_{k=1}^n F(k) \sin \frac{(2k-1)(2i-1)\pi}{4n}, \quad i = 1, \dots, n$$

Forward cosine transform

$$F(k) = \frac{1}{n} [f(0) + f(n) \cos k\pi] + \frac{2}{n} \sum_{i=1}^{n-1} f(i) \cos \frac{ki\pi}{n}, \quad k = 0, \dots, n$$

Backward cosine transform

$$f(i) = \frac{1}{2} [F(0) + F(n) \cos i\pi] + \sum_{k=1}^{n-1} F(k) \cos \frac{ki\pi}{n}, \quad i = 0, \dots, n$$

Forward staggered cosine transform

$$F(k) = \frac{1}{n} f(0) + \frac{2}{n} \sum_{i=1}^{n-1} f(i) \cos \frac{(2k+1)i\pi}{2n}, \quad k = 0, \dots, n-1$$

Backward staggered cosine transform

$$f(i) = \sum_{k=0}^{n-1} F(k) \cos \frac{(2k+1)i\pi}{2n}, \quad i = 0, \dots, n-1$$

Forward staggered2 cosine transform

$$F(k) = \frac{2}{n} \sum_{i=1}^n f(i) \cos \frac{(2k-1)(2i-1)\pi}{4n}, \quad k = 1, \dots, n$$

Backward staggered2 cosine transform

$$f(i) = \sum_{k=1}^n F(k) \cos \frac{(2k-1)(2i-1)\pi}{4n}, \quad i = 1, \dots, n$$

NOTE

The size of the transform n can be any integer greater or equal to 2.

Sequence of Invoking TT Routines

Computation of a transform using TT interface is conceptually divided into four steps, each of which is performed via a dedicated routine. [Table "TT Interface Routines"](#) lists the routines and briefly describes their purpose and use.

Most TT routines have versions operating with single-precision and double-precision data. Names of such routines begin respectively with "s" and "d". The wildcard "?" stands for either of these symbols in routine names.

TT Interface Routines

Routine	Description
<code>?_init_trig_transform</code>	Initializes basic data structures of Trigonometric Transforms.
<code>?_commit_trig_transform</code>	Checks consistency and correctness of user-defined data and creates a data structure to be used by Intel MKL FFT interface ¹ .
<code>?_forward_trig_transform</code> <code>?_backward_trig_transform</code>	Computes a forward/backward Trigonometric Transform of a specified type using the appropriate formula (see Transforms Implemented).
<code>free_trig_transform</code>	Releases the memory used by a data structure needed for calling FFT interface ¹ .

¹TT routines call Intel MKL FFT interface for better performance.

To find a transformed vector for a particular input vector only once, the Intel MKL TT interface routines are normally invoked in the order in which they are listed in [Table "TT Interface Routines"](#).

NOTE

Though the order of invoking TT routines may be changed, it is highly recommended to follow the above order of routine calls.

The diagram in [Figure "Typical Order of Invoking TT Interface Routines"](#) indicates the typical order in which TT interface routines can be invoked in a general case (prefixes and suffixes in routine names are omitted).

Typical Order of Invoking TT Interface Routines

A general scheme of using TT routines for double-precision computations is shown below. A similar scheme holds for single-precision computations with the only difference in the initial letter of routine names.

```
...
    d_init_trig_transform(&n, &tt_type, ipar, dpar, &ir);
/* Change parameters in ipar if necessary. */
/* Note that the result of the Transform will be in f. If you want to preserve the data stored in f,
save it to another location before the function call below */
    d_commit_trig_transform(f, &handle, ipar, dpar, &ir);
    d_forward_trig_transform(f, &handle, ipar, dpar, &ir);
    d_backward_trig_transform(f, &handle, ipar, dpar, &ir);
    free_trig_transform(&handle, ipar, &ir);
/* here the user may clean the memory used by f, dpar, ipar */
...
```

You can find examples of code that uses TT interface routines to solve one-dimensional Helmholtz problem in the `examples\pdetttc\source` folder in your Intel MKL directory.

Interface Description

All types in this documentation are either standard C types `float` and `double` or `MKL_INT` integer type. For more information on the C types, refer to [C Datatypes Specific to Intel MKL](#) and the *Intel(R) MKL User's Guide*. To better understand usage of the types, see examples in the `examples\pdetttc\source` folder in your Intel MKL directory.

Routine Options

All TT routines use parameters to pass various options to one another. These parameters are arrays `ipar`, `dpar` and `spar`. Values for these parameters should be specified very carefully (see [Common Parameters](#)). You can change these values during computations to meet your needs.

WARNING

To avoid failure or incorrect results, you must provide correct and consistent parameters to the routines.

User Data Arrays

TT routines take arrays of user data as input. For example, user arrays are passed to the routine `d_forward_trig_transform` to compute a forward Trigonometric Transform. To minimize storage requirements and improve the overall run-time efficiency, Intel MKL TT routines do not make copies of user input arrays.

NOTE

If you need a copy of your input data arrays, you must save them yourself.

For better performance, align your data arrays as recommended in the *Intel MKL User's Guide* (search the document for coding techniques to improve performance).

TT Routines

The section gives detailed description of TT routines, their syntax, parameters and values they return. Double-precision and single-precision versions of the same routine are described together.

TT routines call Intel MKL FFT interface (described in section "[FFT Functions](#)" in chapter "Fast Fourier Transforms"), which enhances performance of the routines.

?_init_trig_transform

Initializes basic data structures of a Trigonometric Transform.

Syntax

```
void d_init_trig_transform(MKL_INT *n, MKL_INT *tt_type, MKL_INT ipar[], double dpar[], MKL_INT *stat);
```

```
void s_init_trig_transform(MKL_INT *n, MKL_INT *tt_type, MKL_INT ipar[], float spar[], MKL_INT *stat);
```

Include Files

- mkl.h

Input Parameters

<i>n</i>	MKL_INT*. Contains the size of the problem, which should be a positive integer greater than 1. Note that data vector of the transform, which other TT routines will use, must have size $n+1$ for all but staggered2 transforms. Staggered2 transforms require the vector of size n .
<i>tt_type</i>	MKL_INT*. Contains the type of transform to compute, defined via a set of named constants. The following constants are available in the current implementation of TT interface: MKL_SINE_TRANSFORM, MKL_STAGGERED_SINE_TRANSFORM, MKL_STAGGERED2_SINE_TRANSFORM, MKL_COSINE_TRANSFORM, MKL_STAGGERED_COSINE_TRANSFORM, MKL_STAGGERED2_COSINE_TRANSFORM.

Output Parameters

<i>ipar</i>	MKL_INT array of size 128. Contains integer data needed for Trigonometric Transform computations.
<i>dpar</i>	double array of size $5n/2+2$. Contains double-precision data needed for Trigonometric Transform computations.
<i>spar</i>	float array of size $5n/2+2$. Contains single-precision data needed for Trigonometric Transform computations.
<i>stat</i>	MKL_INT*. Contains the routine completion status, which is also written to <i>ipar</i> [6]. The status should be 0 to proceed to other TT routines.

Description

The `?_init_trig_transform` routine initializes basic data structures for Trigonometric Transforms of appropriate precision. After a call to `?_init_trig_transform`, all subsequently invoked TT routines use values of *ipar* and *dpar* (*spar*) array parameters returned by `?_init_trig_transform`. The routine initializes the entire array *ipar*. In the *dpar* or *spar* array, `?_init_trig_transform` initializes elements that do not depend upon the type of transform. For a detailed description of arrays *ipar*, *dpar* and *spar*, refer to the [Common Parameters](#) section. You can skip a call to the initialization routine in your code. For more information, see [Caveat on Parameter Modifications](#).

Return Values

`stat= 0`

The routine successfully completed the task. In general, to proceed with computations, the routine should complete with this `stat` value.

`stat= -99999`

The routine failed to complete the task.

?_commit_trig_transform

Checks consistency and correctness of user's data as well as initializes certain data structures required to perform the Trigonometric Transform.

Syntax

```
void d_commit_trig_transform(double f[], DFTI_DESCRIPTOR_HANDLE *handle, MKL_INT ipar[], double dpar[], MKL_INT *stat);
```

```
void s_commit_trig_transform(float f[], DFTI_DESCRIPTOR_HANDLE *handle, MKL_INT ipar[], float spar[], MKL_INT *stat);
```

Include Files

- `mkh.h`

Input Parameters

`f`

`double` for `d_commit_trig_transform`,

`float` for `s_commit_trig_transform`,

array of size n for staggered2 transforms and of size $n+1$ for all other transforms, where n is the size of the problem. Contains data vector to be transformed. Note that the following values should be 0.0 up to rounding errors:

- $f[0]$ and $f[n]$ for sine transforms
- $f[n]$ for staggered cosine transforms
- $f[0]$ for staggered sine transforms.

Otherwise, the routine will produce a warning, and the result of the computations for sine transforms may be wrong. These restrictions meet the requirements of the Intel MKL Poisson Solver, which the TT interface is primarily designed for (for details, see [Fast Poisson Solver Routines](#)).

`ipar`

`MKL_INT` array of size 128. Contains integer data needed for Trigonometric Transform computations.

`dpar`

`double` array of size $5n/2+2$. Contains double-precision data needed for Trigonometric Transform computations. The routine initializes most elements of this array.

`spar`

`float` array of size $5n/2+2$. Contains single-precision data needed for Trigonometric Transform computations. The routine initializes most elements of this array.

Output Parameters

<i>handle</i>	DFTI_DESCRIPTOR_HANDLE*. The data structure used by Intel MKL FFT interface (for details, refer to section " FFT Functions " in chapter "Fast Fourier Transforms").
<i>ipar</i>	Contains integer data needed for Trigonometric Transform computations. On output, <i>ipar</i> [6] is updated with the <i>stat</i> value.
<i>dpar</i>	Contains double-precision data needed for Trigonometric Transform computations. On output, the entire array is initialized.
<i>spar</i>	Contains single-precision data needed for Trigonometric Transform computations. On output, the entire array is initialized.
<i>stat</i>	MKL_INT*. Contains the routine completion status, which is also written to <i>ipar</i> [6].

Description

The routine `?_commit_trig_transform` checks consistency and correctness of the parameters to be passed to the transform routines `?_forward_trig_transform` and/or `?_backward_trig_transform`. The routine also initializes the following data structures: *handle*, *dpar* in case of `d_commit_trig_transform`, and *spar* in case of `s_commit_trig_transform`. The `?_commit_trig_transform` routine initializes only those elements of *dpar* or *spar* that depend upon the type of transform, defined in the `?_init_trig_transform` routine and passed to `?_commit_trig_transform` with the *ipar* array. The size of the problem *n*, which determines sizes of the array parameters, is also passed to the routine with the *ipar* array and defined in the previously called `?_init_trig_transform` routine. For a detailed description of arrays *ipar*, *dpar* and *spar*, refer to the [Common Parameters](#) section. The routine performs only a basic check for correctness and consistency of the parameters. If you are going to modify parameters of TT routines, see the [Caveat on Parameter Modifications](#) section. Unlike `?_init_trig_transform`, you must call the `?_commit_trig_transform` routine in your code.

Return Values

<i>stat</i> = 11	The routine produced some warnings and made some changes in the parameters to achieve their correctness and/or consistency. You may proceed with computations by assigning <i>ipar</i> [6]=0 if you are sure that the parameters are correct.
<i>stat</i> = 10	The routine made some changes in the parameters to achieve their correctness and/or consistency. You may proceed with computations by assigning <i>ipar</i> [6]=0 if you are sure that the parameters are correct.
<i>stat</i> = 1	The routine produced some warnings. You may proceed with computations by assigning <i>ipar</i> [6]=0 if you are sure that the parameters are correct.
<i>stat</i> = 0	The routine completed the task normally.
<i>stat</i> = -100	The routine stopped for any of the following reasons: • An error in the user's data was encountered.

- Data in *ipar*, *dpar* or *spar* parameters became incorrect and/or inconsistent as a result of modifications.

stat = -1000

The routine stopped because of an FFT interface error.

stat = -10000

The routine stopped because the initialization failed to complete or the parameter *ipar*[0] was altered by mistake.

NOTE

Although positive values of *stat* usually indicate minor problems with the input data and Trigonometric Transform computations can be continued, you are highly recommended to investigate the problem first and achieve *stat*=0.

?_forward_trig_transform

Computes the forward Trigonometric Transform of type specified by the parameter.

Syntax

```
void d_forward_trig_transform(double f[], DFTI_DESCRIPTOR_HANDLE *handle, MKL_INT ipar[], double dpar[], MKL_INT *stat);
```

```
void s_forward_trig_transform(float f[], DFTI_DESCRIPTOR_HANDLE *handle, MKL_INT ipar[], float spar[], MKL_INT *stat);
```

Include Files

- mkl.h

Input Parameters

f

double for d_forward_trig_transform,

float for s_forward_trig_transform,

array of size *n* for staggered2 transforms and of size *n*+1 for all other transforms, where *n* is the size of the problem. On input, contains data vector to be transformed. Note that the following values should be 0.0 up to rounding errors:

- *f*[0] and *f*[*n*] for sine transforms
- *f*[*n*] for staggered cosine transforms
- *f*[0] for staggered sine transforms.

Otherwise, the routine will produce a warning, and the result of the computations for sine transforms may be wrong. The above restrictions meet the requirements of the Intel MKL Poisson Solver, which the TT interface is primarily designed for (for details, see [Fast Poisson Solver Routines](#)).

handle

DFTI_DESCRIPTOR_HANDLE*. The data structure used by Intel MKL FFT interface (for details, see [FFT Functions](#)).

<i>ipar</i>	MKL_INT array of size 128. Contains integer data needed for Trigonometric Transform computations.
<i>dpar</i>	double array of size $5n/2+2$. Contains double-precision data needed for Trigonometric Transform computations.
<i>spar</i>	float array of size $5n/2+2$. Contains single-precision data needed for Trigonometric Transform computations.

Output Parameters

<i>f</i>	Contains the transformed vector on output.
<i>ipar</i>	Contains integer data needed for Trigonometric Transform computations. On output, <i>ipar</i> [6] is updated with the <i>stat</i> value.
<i>stat</i>	MKL_INT*. Contains the routine completion status, which is also written to <i>ipar</i> [6].

Description

The routine computes the forward Trigonometric Transform of type defined in the [?_init_trig_transform](#) routine and passed to [?_forward_trig_transform](#) with the *ipar* array. The size of the problem *n*, which determines sizes of the array parameters, is also passed to the routine with the *ipar* array and defined in the previously called [?_init_trig_transform](#) routine. The other data that facilitates the computation is created by [?_commit_trig_transform](#) and supplied in *dpar* or *spar*. For a detailed description of arrays *ipar*, *dpar* and *spar*, refer to the [Common Parameters](#) section. The routine has a commit step, which calls the [?_commit_trig_transform](#) routine. The transform is computed according to formulas given in the [Transforms Implemented](#) section. The routine replaces the input vector *f* with the transformed vector.

NOTE

If you need a copy of the data vector *f* to be transformed, make the copy before calling the [?_forward_trig_transform](#) routine.

Return Values

<i>stat</i> = 0	The routine completed the task normally.
<i>stat</i> = -100	The routine stopped for any of the following reasons: • An error in the user's data was encountered. • Data in <i>ipar</i>, <i>dpar</i> or <i>spar</i> parameters became incorrect and/or inconsistent as a result of modifications.
<i>stat</i> = -1000	The routine stopped because of an FFT interface error.
<i>stat</i> = -10000	The routine stopped because its commit step failed to complete or the parameter <i>ipar</i> [0] was altered by mistake.

?_backward_trig_transform

Computes the backward Trigonometric Transform of type specified by the parameter.

Syntax

```
void d_backward_trig_transform(double f[], DFTI_DESCRIPTOR_HANDLE *handle, MKL_INT ipar[], double dpar[], MKL_INT *stat);  
void s_backward_trig_transform(float f[], DFTI_DESCRIPTOR_HANDLE *handle, MKL_INT ipar[], float spar[], MKL_INT *stat);
```

Include Files

- `mkh.h`

Input Parameters

<i>f</i>	double for <code>d_backward_trig_transform</code>, float for <code>s_backward_trig_transform</code>, array of size n for staggered2 transforms and of size $n+1$ for all other transforms, where n is the size of the problem. On input, contains data vector to be transformed. Note that the following values should be 0.0 up to rounding errors: • $f[0]$ and $f[n]$ for sine transforms • $f[n]$ for staggered cosine transforms • $f[0]$ for staggered sine transforms. Otherwise, the routine will produce a warning, and the result of the computations for sine transforms may be wrong. The above restrictions meet the requirements of the Intel MKL Poisson Solver, which the TT interface is primarily designed for (for details, see Fast Poisson Solver Routines).
<i>handle</i>	DFTI_DESCRIPTOR_HANDLE*. The data structure used by Intel MKL FFT interface (for details, see FFT Functions).
<i>ipar</i>	MKL_INT array of size 128. Contains integer data needed for Trigonometric Transform computations.
<i>dpar</i>	double array of size $5n/2+2$. Contains double-precision data needed for Trigonometric Transform computations.
<i>spar</i>	float array of size $5n/2+2$. Contains single-precision data needed for Trigonometric Transform computations.

Output Parameters

<i>f</i>	Contains the transformed vector on output.
<i>ipar</i>	Contains integer data needed for Trigonometric Transform computations. On output, <code>ipar[6]</code> is updated with the <code>stat</code> value.
<i>stat</i>	MKL_INT*. Contains the routine completion status, which is also written to <code>ipar[6]</code> .

Description

The routine computes the backward Trigonometric Transform of type defined in the `?_init_trig_transform` routine and passed to `?_backward_trig_transform` with the `ipar` array. The size of the problem n , which determines sizes of the array parameters, is also passed to the routine with the `ipar` array and defined in the previously called `?_init_trig_transform` routine. The other data that facilitates the computation is created by `?_commit_trig_transform` and supplied in `dpar` or `spar`. For a detailed description of arrays `ipar`, `dpar` and `spar`, refer to the [Common Parameters](#) section. The routine has a commit step, which calls the `?_commit_trig_transform` routine. The transform is computed according to formulas given in the [Transforms Implemented](#) section. The routine replaces the input vector f with the transformed vector.

NOTE

If you need a copy of the data vector f to be transformed, make the copy before calling the `?_backward_trig_transform` routine.

Return Values

<code>stat= 0</code>	The routine completed the task normally.
<code>stat= -100</code>	The routine stopped for any of the following reasons: • An error in the user's data was encountered. • Data in <code>ipar</code>, <code>dpar</code> or <code>spar</code> parameters became incorrect and/or inconsistent as a result of modifications.
<code>stat= -1000</code>	The routine stopped because of an FFT interface error.
<code>stat= -10000</code>	The routine stopped because its commit step failed to complete or the parameter <code>ipar[0]</code> was altered by mistake.

free_trig_transform

Cleans the memory allocated for the data structure used by the FFT interface.

Syntax

```
void free_trig_transform(DFTI_DESCRIPTOR_HANDLE *handle, MKL_INT ipar[], MKL_INT *stat);
```

Include Files

- `mkl.h`

Input Parameters

<code>ipar</code>	MKL_INT array of size 128. Contains integer data needed for Trigonometric Transform computations.
<code>handle</code>	DFTI_DESCRIPTOR_HANDLE*. The data structure used by Intel MKL FFT interface (for details, refer to section " FFT Functions " in chapter "Fast Fourier Transforms").

Output Parameters

<i>handle</i>	The data structure used by Intel MKL FFT interface. Memory allocated for the structure is released on output.
<i>ipar</i>	Contains integer data needed for Trigonometric Transform computations. On output, <i>ipar[6]</i> is updated with the <i>stat</i> value.
<i>stat</i>	MKL_INT*. Contains the routine completion status, which is also written to <i>ipar[6]</i> .

Description

The `free_trig_transform` routine cleans the memory used by the *handle* structure, needed for Intel MKL FFT functions. To release the memory allocated for other parameters, include cleaning of the memory in your code.

Return Values

<i>stat</i> = 0	The routine completed the task normally.
<i>stat</i> = -1000	The routine stopped because of an FFT interface error.
<i>stat</i> = -99999	The routine failed to complete the task.

Common Parameters

This section provides description of array parameters that hold TT routine options: *ipar*, *dpar* and *spar*.

NOTE

Initial values are assigned to the array parameters by the appropriate `?_init_trig_transform` and `?_commit_trig_transform` routines.

<i>ipar</i>	MKL_INT array of size 128, holds integer data needed for Trigonometric Transform computations. Its elements are described in Table "Elements of the ipar Array" :

Elements of the ipar Array

Index	Description
0	Contains the size of the problem to solve. The <code>?_init_trig_transform</code> routine sets <i>ipar[0]=n</i> , and all subsequently called TT routines use <i>ipar[0]</i> as the size of the transform.
1	Contains error messaging options: <i>ipar[1]=-1</i> indicates that all error messages will be printed to the file <code>MKL_Trig_Transforms_log.txt</code> in the folder from which the routine is called. If the file does not exist, the routine tries to create it. If the attempt fails, the routine prints information that the file cannot be created to the standard output device. <i>ipar[1]=0</i> indicates that no error messages will be printed. <i>ipar[1]=1</i> (default) indicates that all error messages will be printed to the preconnected default output device (usually, screen).

Index	Description
	In case of errors, each TT routine assigns a non-zero value to <i>stat</i> regardless of the <i>ipar[1]</i> setting.
2	Contains warning messaging options: • <i>ipar[2]=-1</i> indicates that all warning messages will be printed to the file <code>MKL_Trig_Transforms_log.txt</code> in the directory from which the routine is called. If the file does not exist, the routine tries to create it. If the attempt fails, the routine prints information that the file cannot be created to the standard output device. • <i>ipar[2]=0</i> indicates that no warning messages will be printed. • <i>ipar[2]=1</i> (default) indicates that all warning messages will be printed to the preconnected default output device (usually, screen). In case of warnings, the <i>stat</i> parameter will acquire a non-zero value regardless of the <i>ipar[2]</i> setting.
3 through 4	Reserved for future use.
5	Contains the type of the transform. The <code>?_init_trig_transform</code> routine sets <i>ipar[5]=tt_type</i> , and all subsequently called TT routines use <i>ipar[5]</i> as the type of the transform.
6	Contains the <i>stat</i> value returned by the last completed TT routine. Used to check that the previous call to a TT routine completed with <i>stat</i> =0.
7	Informs the <code>?_commit_trig_transform</code> routines whether to initialize data structures <i>dpar</i> (<i>spar</i>) and <i>handle</i>. <i>ipar[7]=0</i> indicates that the routine should skip the initialization and only check correctness and consistency of the parameters. Otherwise, the routine initializes the data structures. The default value is 1. The possibility to check correctness and consistency of input data without initializing data structures <i>dpar</i>, <i>spar</i> and <i>handle</i> enables avoiding performance losses in a repeated use of the same transform for different data vectors. Note that you can benefit from the opportunity that <i>ipar[7]</i> gives only if you are sure to have supplied proper tolerance value in the <i>dpar</i> or <i>spar</i> array. Otherwise, avoid tuning this parameter.
8	Contains message style options for TT routines. Specifically, if <i>ipar[8]</i> is non-zero, TT routines print the messages in C-style notations. The default value is 1. When specifying message style options, be aware that by default, numbering of elements in C arrays starts at 0. For example, "<i>parameter ipar[0]=3 should be an even integer</i>" is a C-style message. The use of <i>ipar[8]</i> enables you to view messages in a more convenient style.
9	Specifies the number of OpenMP threads to run TT routines in the OpenMP environment of the Intel MKL Poisson Solver. The default value is 1. You are highly recommended not to alter this value. See also Caveat on Parameter Modifications .
10	Specifies the mode of compatibility with FFTW. The default value is 0. Set the value to 1 to invoke compatibility with FFTW. In the latter case, results will not be normalized, because FFTW does not do this. It is highly recommended not to alter this value, but rather use real-to-real FFTW to MKL wrappers, described in FTW to Intel® MKL Wrappers for FFTW 3.x . See also Caveat on Parameter Modifications .
11 through 127	Reserved for future use.

NOTE

While you can declare the *ipar* array as `MKL_INT ipar[11]`, for future compatibility you should declare *ipar* as `MKL_INT ipar[128]`.

Arrays *dpar* and *spar* are the same except in the data precision:

<i>dpar</i>	double array of size $5n/2+2$, holds data needed for double-precision routines to perform TT computations. This array is initialized in the <code>d_init_trig_transform</code> and <code>d_commit_trig_transform</code> routines.
<i>spar</i>	float array of size $5n/2+2$, holds data needed for single-precision routines to perform TT computations. This array is initialized in the <code>s_init_trig_transform</code> and <code>s_commit_trig_transform</code> routines.

As *dpar* and *spar* have similar elements in respective positions, the elements are described together in Table "Elements of the *dpar* and *spar* Arrays":

Elements of the *dpar* and *spar* Arrays

Index	Description
0	Contains the first absolute tolerance used by the appropriate <code>?_commit_trig_transform</code> routine. For a staggered cosine or a sine transform, $f[n]$ should be equal to 0.0 and for a staggered sine or a sine transform, $f[0]$ should be equal to 0.0. The <code>?_commit_trig_transform</code> routine checks whether absolute values of these parameters are below $dpar[0]*n$ or $spar[0]*n$, depending on the routine precision. To suppress warnings resulting from tolerance checks, set $dpar[0]$ or $spar[0]$ to a sufficiently large number.
1	Reserved for future use.
2 through $5n/2+1$	Contain tabulated values of trigonometric functions. Contents of the elements depend upon the type of transform <i>tt_type</i> , set up in the <code>?_commit_trig_transform</code> routine: - If <i>tt_type</i>=<code>MKL_SINE_TRANSFORM</code>, the transform uses only the first $n/2$ array elements, which contain tabulated sine values. - If <i>tt_type</i>=<code>MKL_STAGGERED_SINE_TRANSFORM</code>, the transform uses only the first $3n/2$ array elements, which contain tabulated sine and cosine values. - If <i>tt_type</i>=<code>MKL_STAGGERED2_SINE_TRANSFORM</code>, the transform uses all the $5n/2$ array elements, which contain tabulated sine and cosine values. - If <i>tt_type</i>=<code>MKL_COSINE_TRANSFORM</code>, the transform uses only the first n array elements, which contain tabulated cosine values. - If <i>tt_type</i>=<code>MKL_STAGGERED_COSINE_TRANSFORM</code>, the transform uses only the first $3n/2$ elements, which contain tabulated sine and cosine values. - If <i>tt_type</i>=<code>MKL_STAGGERED2_COSINE_TRANSFORM</code>, the transform uses all the $5n/2$ elements, which contain tabulated sine and cosine values.

NOTE

To save memory, you can define the array size depending upon the type of transform.

Caveat on Parameter Modifications

Flexibility of the TT interface enables you to skip a call to the `?_init_trig_transform` routine and to initialize the basic data structures explicitly in your code. You may also need to modify the contents of *ipar*, *dpar* and *spar* arrays after initialization. When doing so, provide correct and consistent data in the arrays.

Mistakenly altered arrays cause errors or wrong computation. You can perform a basic check for correctness and consistency of parameters by calling the `?_commit_trig_transform` routine; however, this does not ensure the correct result of a transform but only reduces the chance of errors or wrong results.

NOTE

To supply correct and consistent parameters to TT routines, you should have considerable experience in using the TT interface and good understanding of elements that the *ipar*, *spar* and *dpar* arrays contain and dependencies between values of these elements.

However, in rare occurrences, even advanced users might fail to compute a transform using TT routines after the parameter modifications. In cases like these, refer for technical support at <http://www.intel.com/software/products/support/>.

WARNING

The only way that ensures proper computation of the Trigonometric Transforms is to follow a typical sequence of invoking the routines and not change the default set of parameters. So, avoid modifications of *ipar*, *dpar* and *spar* arrays unless a strong need arises.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Implementation Details

Several aspects of the Intel MKL TT interface are platform-specific and language-specific. To promote portability across platforms and ease of use across different languages, Intel MKL provides you with the TT language-specific header file to include in your code:

- `mkl_trig_transforms.h`, to be used together with `mkl_dfti.h`.

NOTE

- Use of the Intel MKL TT software without including the above language-specific header files is not supported.

Header File

The header file below defines the following function prototypes:

```
void d_init_trig_transform(MKL_INT *, MKL_INT *, MKL_INT *, double *, MKL_INT *);
void d_commit_trig_transform(double *, DFTI_DESCRIPTOR_HANDLE *, MKL_INT *, double *, MKL_INT *);
void d_forward_trig_transform(double *, DFTI_DESCRIPTOR_HANDLE *, MKL_INT *, double *, MKL_INT *);
void d_backward_trig_transform(double *, DFTI_DESCRIPTOR_HANDLE *, MKL_INT *, double *, MKL_INT *);

void s_init_trig_transform(MKL_INT *, MKL_INT *, MKL_INT *, float *, MKL_INT *);
void s_commit_trig_transform(float *, DFTI_DESCRIPTOR_HANDLE *, MKL_INT *, float *, MKL_INT *);
void s_forward_trig_transform(float *, DFTI_DESCRIPTOR_HANDLE *, MKL_INT *, float *, MKL_INT *);
```

```
void s_backward_trig_transform(float *, DFTI_DESCRIPTOR_HANDLE *, MKL_INT *, float *, MKL_INT *);  
  
void free_trig_transform(DFTI_DESCRIPTOR_HANDLE *, MKL_INT *, MKL_INT *);
```

Fast Poisson Solver Routines

In addition to the Real Discrete Trigonometric Transforms (TT) interface (refer to [Trigonometric Transform Routines](#)), Intel MKL supports the the Poisson Solver interface. This interface implements a group of routines (Poisson Solver routines) used to compute a solution of Laplace, Poisson, and Helmholtz problems of a special kind using discrete Fourier transforms. Laplace and Poisson problems are special cases of a more general Helmholtz problem. The problems that are solved by the Poisson Solver interface are defined more exactly in the [Poisson Solver Implementation](#) subsection. The Poisson Solver interface provides much flexibility of use: you can call routines with the default parameter values or adjust routines to your particular needs by manually tuning routine parameters. You can adjust the style of error and warning messages to a C notation by setting up a dedicated parameter. This adds convenience to debugging, because you can read information in the way that is natural for your code. The Intel MKL Poisson Solver interface currently contains only routines that implement the following solvers:

- Fast Laplace, Poisson and Helmholtz solvers in a Cartesian coordinate system
- Fast Poisson and Helmholtz solvers in a spherical coordinate system.

Poisson Solver Implementation

Poisson Solver routines enable approximate solving of certain two-dimensional and three-dimensional problems. [Figure "Structure of the Poisson Solver"](#) shows the general structure of the Poisson Solver.

Structure of the Poisson Solver

**NOTE**

Although in the Cartesian case, both periodic and non-periodic solvers are also supported, they use the same interfaces.

Sections below provide details of the problems that can be solved using Intel MKL Poisson Solver.

Two-Dimensional Problems

Notational Conventions

The Poisson Solver interface description uses the following notation for boundaries of a rectangular domain $a_x < x < b_x$, $a_y < y < b_y$ on a Cartesian plane:

$$bd\_a_x = \{x = a_x, a_y \leq y \leq b_y\}, \quad bd\_b_x = \{x = b_x, a_y \leq y \leq b_y\}$$

$$bd\_a_y = \{a_x \leq x \leq b_x, y = a_y\}, \quad bd\_b_y = \{a_x \leq x \leq b_x, y = b_y\}.$$

The following figure shows these boundaries:

The wildcard "+" may stand for any of the symbols a_x , b_x , a_y , b_y , so bd_+ denotes any of the above boundaries.

The Poisson Solver interface description uses the following notation for boundaries of a rectangular domain $a_\varphi < \varphi < b_\varphi$, $a_\theta < \theta < b_\theta$ on a sphere $0 \leq \varphi \leq 2\pi$, $0 \leq \theta \leq \pi$:

$$bd\_a_\varphi = \{\varphi = a_\varphi, a_\theta \leq \theta \leq b_\theta\}, \quad bd\_b_\varphi = \{\varphi = b_\varphi, a_\theta \leq \theta \leq b_\theta\},$$

$$bd\_a_\theta = \{a_\varphi \leq \varphi \leq b_\varphi, \theta = a_\theta\}, \quad bd\_b_\theta = \{a_\varphi \leq \varphi \leq b_\varphi, \theta = b_\theta\}.$$

The wildcard "~" may stand for any of the symbols a_φ , b_φ , a_θ , b_θ , so $bd\_~$ denotes any of the above boundaries.

Two-dimensional Helmholtz problem on a Cartesian plane

The two-dimensional (2D) Helmholtz problem is to find an approximate solution of the Helmholtz equation

$$-\frac{\partial^2 u}{\partial x^2} - \frac{\partial^2 u}{\partial y^2} + qu = f(x, y), \quad q = \text{const} \geq 0$$

in a rectangle, that is, a rectangular domain $a_x < x < b_x$, $a_y < y < b_y$, with one of the following boundary conditions on each boundary bd_+ :

- The Dirichlet boundary condition

$$u(x, y) = G(x, y)$$

- The Neumann boundary condition

$$\frac{\partial u}{\partial n}(x, y) = g(x, y)$$

where

$$n = -x \text{ on } bd\_a_x, n = x \text{ on } bd\_b_x,$$

$$n = -y \text{ on } bd\_a_y, n = y \text{ on } bd\_b_y.$$

- Periodic boundary conditions

$$u(a_x, y) = u(b_x, y), \quad \frac{\partial}{\partial x} u(a_x, y) = \frac{\partial}{\partial x} u(b_x, y),$$

$$u(x, a_y) = u(x, b_y), \quad \frac{\partial}{\partial y} u(x, a_y) = \frac{\partial}{\partial y} u(x, b_y).$$

Two-dimensional Poisson problem on a Cartesian plane

The Poisson problem is a special case of the Helmholtz problem, when $q=0$. The 2D Poisson problem is to find an approximate solution of the Poisson equation

$$-\frac{\partial^2 u}{\partial x^2} - \frac{\partial^2 u}{\partial y^2} = f(x, y)$$

in a rectangle $a_x < x < b_x$, $a_y < y < b_y$ with the Dirichlet, Neumann, or periodic boundary conditions on each boundary bd_+ . In case of a problem with the Neumann boundary condition on the entire boundary, you can find the solution of the problem only up to a constant. In this case, the Poisson Solver will compute the solution that provides the minimal Euclidean norm of a residual.

Two-dimensional (2D) Laplace problem on a Cartesian plane

The Laplace problem is a special case of the Helmholtz problem, when $q=0$ and $f(x, y)=0$. The 2D Laplace problem is to find an approximate solution of the Laplace equation

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = 0$$

in a rectangle $a_x < x < b_x$, $a_y < y < b_y$ with the Dirichlet, Neumann, or periodic boundary conditions on each boundary bd_+ .

Helmholtz problem on a sphere

The Helmholtz problem on a sphere is to find an approximate solution of the Helmholtz equation

$$-\Delta_s u + qu = f, \quad q = \text{const} \geq 0,$$

$$\Delta_s = \frac{1}{\sin^2 \theta} \frac{\partial^2}{\partial \varphi^2} + \frac{1}{\sin \theta} \frac{\partial}{\partial \theta} \left(\sin \theta \frac{\partial}{\partial \theta} \right)$$

in a domain bounded by angles $a_\varphi \leq \varphi \leq b_\varphi$, $a_\theta \leq \theta \leq b_\theta$ (spherical rectangle), with boundary conditions for particular domains listed in [Table "Details of Helmholtz Problem on a Sphere"](#).

Details of Helmholtz Problem on a Sphere

Domain on a sphere	Boundary condition	Periodic/non-periodic case
Rectangular, that is, $b_\varphi - a_\varphi < 2\pi$ and $b_\theta - a_\theta < \pi$	Homogeneous Dirichlet boundary conditions on each boundary $bd\_~$	<i>non-periodic</i>
Where $a_\varphi = 0$, $b_\varphi = 2\pi$, and $b_\theta - a_\theta < \pi$	Homogeneous Dirichlet boundary conditions on the boundaries bd_a_θ and bd_b_θ	<i>periodic</i>

Domain on a sphere	Boundary condition	Periodic/non-periodic case
Entire sphere, that is, $a_\varphi = 0$, $b_\varphi = 2\pi$, $a_\theta = 0$, and $b_\theta = \pi$	Boundary condition $\left(\sin \theta \frac{\partial u}{\partial \theta}\right) = 0$ $\theta \rightarrow 0$ $\theta \rightarrow \pi$ at the poles	periodic

Poisson problem on a sphere

The Poisson problem is a special case of the Helmholtz problem, when $q=0$. The Poisson problem on a sphere is to find an approximate solution of the Poisson equation

$$-\Delta_s u = f, \Delta_s = \frac{1}{\sin^2 \theta} \frac{\partial^2}{\partial \varphi^2} + \frac{1}{\sin \theta} \frac{\partial}{\partial \theta} \left(\sin \theta \frac{\partial}{\partial \theta} \right)$$

in a spherical rectangle $a_\varphi \leq \varphi \leq b_\varphi$, $a_\theta \leq \theta \leq b_\theta$ in cases listed in [Table "Details of Helmholtz Problem on a Sphere"](#). The solution to the Poisson problem on the entire sphere can be found up to a constant only. In this case, Poisson Solver will compute the solution that provides the minimal Euclidean norm of a residual.

Approximation of 2D problems

To find an approximate solution for any of the 2D problems, in the rectangular domain a uniform mesh can be defined for the Cartesian case as:

$$\{x_i = a_x + ih_x, y_j = a_y + jh_y\},$$

$$i = 0, \dots, n_x, j = 0, \dots, n_y, h_x = \frac{b_x - a_x}{n_x}, h_y = \frac{b_y - a_y}{n_y}$$

and for the spherical case as:

$$\{\varphi_i = a_\varphi + ih_\varphi, \theta_j = a_\theta + jh_\theta\},$$

$$i = 0, \dots, n_\varphi, j = 0, \dots, n_\theta, h_\varphi = \frac{b_\varphi - a_\varphi}{n_\varphi}, h_\theta = \frac{b_\theta - a_\theta}{n_\theta}.$$

The Poisson Solver uses the standard five-point finite difference approximation on this mesh to compute the approximation to the solution:

- In the Cartesian case, the values of the approximate solution will be computed in the mesh points (x_i, y_j) provided that you can supply the values of the right-hand side $f(x, y)$ in these points and the values of the appropriate boundary functions $G(x, y)$ and/or $g(x, y)$ in the mesh points laying on the boundary of the rectangular domain.
- In the spherical case, the values of the approximate solution will be computed in the mesh points (φ_i, θ_j) provided that you can supply the values of the right-hand side $f(\varphi, \theta)$ in these points.

NOTE

The number of mesh intervals n_φ in the φ direction of a spherical mesh must be even in the periodic case. The Poisson Solver does not support spherical meshes that do not meet this condition.

Three-Dimensional Problems

Notational Conventions

The Poisson Solver interface description uses the following notation for boundaries of a parallelepiped domain $a_x < x < b_x$, $a_y < y < b_y$, $a_z < z < b_z$:

$$bd\_a_x = \{x = a_x, a_y \leq y \leq b_y, a_z \leq z \leq b_z\}, bd\_b_x = \{x = b_x, a_y \leq y \leq b_y, a_z \leq z \leq b_z\},$$

$$bd\_a_y = \{a_x \leq x \leq b_x, y = a_y, a_z \leq z \leq b_z\}, bd\_b_y = \{a_x \leq x \leq b_x, y = b_y, a_z \leq z \leq b_z\},$$

$bd\_a_z = \{a_x \leq x \leq b_x, a_y \leq y \leq b_y, z = a_z\}$, $bd\_b_x = \{a_x \leq x \leq b_x, a_y \leq y \leq b_y, z = b_z\}$.

The following figure shows these boundaries:

The wildcard "+" may stand for any of the symbols $a_x, b_x, a_y, b_y, a_z, b_z$, so bd_+ denotes any of the above boundaries.

Three-dimensional (3D) Helmholtz problem

The 3D Helmholtz problem is to find an approximate solution of the Helmholtz equation

$$-\frac{\partial^2 u}{\partial x^2} - \frac{\partial^2 u}{\partial y^2} - \frac{\partial^2 u}{\partial z^2} + qu = f(x, y, z), \quad q = \text{const} \geq 0$$

in a parallelepiped, that is, a parallelepiped domain $a_x < x < b_x, a_y < y < b_y, a_z < z < b_z$, with one of the following boundary conditions on each boundary bd_+ :

- The Dirichlet boundary condition
- The Neumann boundary condition

$$\frac{\partial u}{\partial n}(x, y, z) = g(x, y, z)$$

where

$$n = -x \text{ on } bd\_a_x, n = x \text{ on } bd\_b_x,$$

$$n = -y \text{ on } bd\_a_y, n = y \text{ on } bd\_b_y,$$

$$n = -z \text{ on } bd\_a_z, n = z \text{ on } bd\_b_z.$$

- Periodic boundary conditions

$$u(a_x, y, z) = u(b_x, y, z), \quad \frac{\partial}{\partial x} u(a_x, y, z) = \frac{\partial}{\partial x} u(b_x, y, z),$$

$$u(x, a_y, z) = u(x, b_y, z), \quad \frac{\partial}{\partial y} u(x, a_y, z) = \frac{\partial}{\partial y} u(x, b_y, z),$$

$$u(x, y, a_z) = u(x, y, b_z), \quad \frac{\partial}{\partial z} u(x, y, a_z) = \frac{\partial}{\partial z} u(x, y, b_z).$$

Three-dimensional (3D) Poisson problem

The Poisson problem is a special case of the Helmholtz problem, when $q=0$. The 3D Poisson problem is to find an approximate solution of the Poisson equation

$$-\frac{\partial^2 u}{\partial x^2} - \frac{\partial^2 u}{\partial y^2} - \frac{\partial^2 u}{\partial z^2} = f(x, y, z)$$

in a parallelepiped $a_x < x < b_x$, $a_y < y < b_y$, $a_z < z < b_z$ with the Dirichlet, Neumann, or periodic boundary conditions on each boundary bd_{-+} .

Three-dimensional (3D) Laplace problem

The Laplace problem is a special case of the Helmholtz problem, when $q=0$ and $f(x, y, z)=0$. The 3D Laplace problem is to find an approximate solution of the Laplace equation

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} + \frac{\partial^2 u}{\partial z^2} = 0$$

in a parallelepiped $a_x < x < b_x$, $a_y < y < b_y$, $a_z < z < b_z$ with the Dirichlet, Neumann, or periodic boundary conditions on each boundary bd_{-+} .

Approximation of 3D problems

To find an approximate solution for each of the 3D problems, a uniform mesh can be defined in the parallelepiped domain as:

$$\{x_i = a_x + ih_x, y_j = a_y + jh_y, z_k = a_z + kh_z\},$$

where

$$i = 0, \dots, n_x, \quad j = 0, \dots, n_y, \quad k = 0, \dots, n_z,$$

$$h_x = \frac{b_x - a_x}{n_x}, \quad h_y = \frac{b_y - a_y}{n_y}, \quad h_z = \frac{b_z - a_z}{n_z}.$$

The Poisson Solver uses the standard seven-point finite difference approximation on this mesh to compute the approximation to the solution. The values of the approximate solution will be computed in the mesh points (x_i, y_j, z_k) , provided that you can supply the values of the right-hand side $f(x, y, z)$ in these points and the values of the appropriate boundary functions $G(x, y, z)$ and/or $g(x, y, z)$ in the mesh points laying on the boundary of the parallelepiped domain.

Sequence of Invoking Poisson Solver Routines

NOTE

This description always shows the solution process for the Helmholtz problem, because Fast Poisson Solvers and Fast Laplace Solvers are special cases of Fast Helmholtz Solvers (see [Poisson Solver Implementation](#)).

The Poisson Solver interface enables you to compute a solution of the Helmholtz problem in four steps. Each step is performed by a dedicated routine. [Table "Poisson Solver Interface Routines"](#) lists the routines and briefly describes their purpose.

Most Poisson Solver routines have versions operating with single-precision and double-precision data. Names of such routines begin respectively with "s" and "d". The wildcard "?" stands for either of these symbols in routine names. The routines for the Cartesian coordinate system have 2D and 3D versions. Their names end respectively in "2D" and "3D". The routines for spherical coordinate system have periodic and non-periodic versions. Their names end respectively in "p" and "np".

Poisson Solver Interface Routines

Routine	Description
<code>?_init_Helmholtz_2D/?_init_Helmholtz_3D/?_init_sph_p/?_init_sph_np</code>	Initializes basic data structures for Fast Helmholtz Solver in the 2D/3D/periodic/non-periodic case, respectively.
<code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D/?_commit_sph_p/?_commit_sph_np</code>	Checks consistency and correctness of input data and initializes data structures for the solver, including those used by the Intel MKL FFT interface ¹ .
<code>?_Helmholtz_2D/?_Helmholtz_3D/?_sph_p/?_sph_np</code>	Computes an approximate solution of the 2D/3D/periodic/non-periodic Helmholtz problem (see Poisson Solver Implementation) specified by the parameters.
<code>free_Helmholtz_2D/free_Helmholtz_3D/free_sph_p/free_sph_np</code>	Releases the memory used by the data structures needed for calling the Intel MKL FFT interface ¹ .

¹ Poisson Solver routines call the Intel MKL FFT interface for better performance.

To find an approximate solution of Helmholtz problem only once, the Intel MKL Poisson Solver interface routines are normally invoked in the order in which they are listed in [Table "Poisson Solver Interface Routines"](#).

NOTE

Though the order of invoking Poisson Solver routines may be changed, it is highly recommended to follow the above order of routine calls.

The diagram in [Figure "Typical Order of Invoking Poisson Solver Routines"](#) indicates the typical order in which Poisson Solver routines can be invoked in a general case.

Typical Order of Invoking Poisson Solver Routines

A general scheme of using Poisson Solver routines for double-precision computations in a 3D Cartesian case is shown below. You can change this scheme to a scheme for single-precision computations by changing the initial letter of the Poisson Solver routine names from "d" to "s". You can also change the scheme below from the 3D to 2D case by changing the ending of the Poisson Solver routine names.

```
...
d_init_Helmholtz_3D(&ax, &bx, &ay, &by, &az, &bz, &nx, &ny, &nz, Bctype, ipar, dpar, &stat);
/* change parameters in ipar and/or dpar if necessary. */
/* note that the result of the Fast Helmholtz Solver will be in f. If you want to keep the data
that is stored in f, save it to another location before the function call below */
d_commit_Helmholtz_3D(f, bd_ax, bd_bx, bd_ay, bd_by, bd_az, bd_bz, &xhandle, &yhandle, ipar, dpar,
&stat);
d_Helmholtz_3D(f, bd_ax, bd_bx, bd_ay, bd_by, bd_az, bd_bz, &xhandle, &yhandle, ipar, dpar, &stat);
free_Helmholtz_3D (&xhandle, &yhandle, ipar, &stat);
/* here you may clean the memory used by f, dpar, ipar */
...
```

A general scheme of using Poisson Solver routines for double-precision computations in a spherical periodic case is shown below. You can change this scheme to a scheme for single-precision computations by changing the initial letter of the Poisson Solver routine names from "d" to "s". You can also change the scheme below to a scheme for a non-periodic case by changing the ending of the Poisson Solver routine names from "p" to "np".

```
...
d_init_sph_p(&ap, &bp, &at, &bt, &np, &nt, &q, ipar, dpar, &stat);
/* change parameters in ipar and/or dpar if necessary. */
/* note that the result of the Fast Helmholtz Solver will be in f. If you want to keep the data
that is stored in f, save it to another location before the function call below */
d_commit_sph_p(f, &handle_s, &handle_c, ipar, dpar, &stat);
d_sph_p(f, &handle_s, &handle_c, ipar, dpar, &stat);
free_sph_p(&handle_s, &handle_c, ipar, &stat);
/* here you may clean the memory used by f, dpar, ipar */
...
```

You can find examples of code that uses Poisson Solver routines to solve Helmholtz problem (in both Cartesian and spherical cases) in the `examples\pdepoissonc\source` folder in your Intel MKL directory.

Interface Description

All numerical types in this section are either standard C types `float` and `double` or MKL `INT` integer type. For more information on the C types, refer to [C Datatypes Specific to Intel MKL](#) and the *Intel(R) MKL User's Guide*. To better understand usage of the types, see examples in the `examples\pdepoissonc\source` folder in your Intel MKL directory.

Routine Options

All Poisson Solver routines use parameters for passing various options to the routines. These parameters are arrays `ipar`, `dpar`, and `spar`. Values for these parameters should be specified very carefully (see [Common Parameters](#)). You can change these values during computations to meet your needs. For more details, see the descriptions of specific routines.

WARNING

To avoid failure or incorrect results, you must provide correct and consistent parameters to the routines.

User Data Arrays

Poisson Solver routines take arrays of user data as input. For example, the `d_Helmholtz_3D` routine takes user arrays to compute an approximate solution to the 3D Helmholtz problem. To minimize storage requirements and improve the overall run-time efficiency, Intel MKL Poisson Solver routines do not make copies of user input arrays.

NOTE

If you need a copy of your input data arrays, you must save them yourself.

For better performance, align your data arrays as recommended in the *Intel MKL User's Guide* (search the document for coding techniques to improve performance).

Routines for the Cartesian Solver

The section describes Poisson Solver routines for the Cartesian case, their syntax, parameters, and return values. All flavors of the same routine are described together: single- and double-precision and 2D and 3D.

NOTE

Some of the routine parameters are used only in the 3D Fast Helmholtz Solver.

Poisson Solver routines call Intel MKL FFT routines (described in section "[FFT Functions](#)" in chapter "Fast Fourier Transforms"), which enhance performance of the Poisson Solver routines.

?_init_Helmholtz_2D/?_init_Helmholtz_3D

Initializes basic data structures of the Fast 2D/3D Helmholtz Solver.

Syntax

```
void d_init_Helmholtz_2D (const double * ax, const double * bx, const double * ay,
const double * by, const MKL_INT * nx, const MKL_INT * ny, const char * Bctype, const
double * q, MKL_INT * ipar, double * dpar, MKL_INT * stat);

void s_init_Helmholtz_2D (const float * ax, const float * bx, const float * ay, const
float * by, const MKL_INT * nx, const MKL_INT * ny, const char * Bctype, const float *
q, MKL_INT * ipar, float * spar, MKL_INT * stat);

void d_init_Helmholtz_3D (const double * ax, const double * bx, const double * ay,
const double * by, const double * az, const double * bz, const MKL_INT * nx, const
MKL_INT * ny, const MKL_INT * nz, const char * Bctype, const double * q, MKL_INT
*ipar, double * dpar, MKL_INT * stat);

void s_init_Helmholtz_3D (const float * ax, const float * bx, const float * ay, const
float * by, const float * az, const float * bz, const MKL_INT * nx, const MKL_INT *
ny, const MKL_INT * nz, const char * Bctype, const float * q, MKL_INT * ipar, float *
spar, MKL_INT * stat);
```

Include Files

- `mkh.h`

Input Parameters

`ax` double* for d_init_Helmholtz_2D/d_init_Helmholtz_3D,

	float* for s_init_Helmholtz_2D/s_init_Helmholtz_3D.
	The coordinate of the leftmost boundary of the domain along the x-axis.
<i>bx</i>	double* for d_init_Helmholtz_2D/d_init_Helmholtz_3D, float* for s_init_Helmholtz_2D/s_init_Helmholtz_3D.
	The coordinate of the rightmost boundary of the domain along the x-axis.
<i>ay</i>	double* for d_init_Helmholtz_2D/d_init_Helmholtz_3D, float* for s_init_Helmholtz_2D/s_init_Helmholtz_3D.
	The coordinate of the leftmost boundary of the domain along the y-axis.
<i>by</i>	double* for d_init_Helmholtz_2D/d_init_Helmholtz_3D, float* for s_init_Helmholtz_2D/s_init_Helmholtz_3D.
	The coordinate of the rightmost boundary of the domain along the y-axis.
<i>az</i>	double* for d_init_Helmholtz_3D, float* for s_init_Helmholtz_3D.
	The coordinate of the leftmost boundary of the domain along the z-axis. This parameter is needed only for the ?_init_Helmholtz_3D routine.
<i>bz</i>	double* for d_init_Helmholtz_3D, float* for s_init_Helmholtz_3D.
	The coordinate of the rightmost boundary of the domain along the z-axis. This parameter is needed only for the ?_init_Helmholtz_3D routine.
<i>nx</i>	MKL_INT*. The number of mesh intervals along the x-axis.
<i>ny</i>	MKL_INT*. The number of mesh intervals along the y-axis.
<i>nz</i>	MKL_INT*. The number of mesh intervals along the z-axis. This parameter is needed only for the ?_init_Helmholtz_3D routine.
<i>BCtype</i>	char*. Contains the type of boundary conditions on each boundary. Must contain four characters for ?_init_Helmholtz_2D and six characters for ? _init_Helmholtz_3D. Each of the characters can be 'N' (Neumann boundary condition), 'D' (Dirichlet boundary condition), or 'P' (periodic boundary conditions). Specify the types of boundary conditions for the boundaries in the following order: <i>bd_ax</i> , <i>bd_bx</i> , <i>bd_ay</i> , <i>bd_by</i> , <i>bd_az</i> , and <i>bd_bz</i> . Specify periodic boundary conditions on the respective boundaries in pairs (for example, 'PPDD' or 'NNPP' in the 2D case). The types of boundary conditions for the last two boundaries are needed only in the 3D case.
<i>q</i>	double* for d_init_Helmholtz_2D/d_init_Helmholtz_3D, float* for s_init_Helmholtz_2D/s_init_Helmholtz_3D.
	The constant Helmholtz coefficient. Note that to solve Poisson or Laplace problem, you should set the value of <i>q</i> to 0.

Output Parameters

<i>ipar</i>	MKL_INT array of size 128. Contains integer data to be used by Fast Helmholtz Solver (for details, refer to ipar).
<i>dpar</i>	double array of size $5 \times nx/2 + 7$ in the 2D case or $5 \times (nx + ny)/2 + 9$ in the 3D case. Contains double-precision data to be used by Fast Helmholtz Solver (for details, refer to dpar and spar).
<i>spar</i>	float array of size $5 \times nx/2 + 7$ in the 2D case or $5 \times (nx + ny)/2 + 9$ in the 3D case. Contains single-precision data to be used by Fast Helmholtz Solver (for details, refer to dpar and spar).
<i>stat</i>	MKL_INT*. Routine completion status, which is also written to <i>ipar</i> [0]. Continue to call other Poisson Solver routines only if the status is 0.

Description

The `?_init_Helmholtz_2D/?_init_Helmholtz_3D` routines initialize basic data structures for Poisson Solver computations of the appropriate precision. All routines invoked after a call to a `?_init_Helmholtz_2D/?_init_Helmholtz_3D` routine use values of the *ipar*, *dpar* and *spar* array parameters returned by the routine. Detailed description of the array parameters can be found in [Common Parameters](#).

CAUTION

Data structures initialized and created by 2D flavors of the routine cannot be used by 3D flavors of any Poisson Solver routines, and vice versa.

You can skip calls to these routines in your code. However, see [Caveat on Parameter Modifications](#) for information on initializing the data structures.

Return Values

<i>stat</i> = 0	The routine successfully completed the task. In general, to proceed with computations, the routine should complete with this <i>stat</i> value.
<i>stat</i> = -99999	The routine failed to complete the task because of a fatal error.

[_commit_Helmholtz_2D/?_commit_Helmholtz_3D](#)

Checks consistency and correctness of input data and initializes certain data structures required to solve 2D/3D Helmholtz problem.

Syntax

```
void d_commit_Helmholtz_2D (double * f, const double * bd_ax, const double * bd_bx,
const double * bd_ay, const double * bd_by, DFTI_DESCRIPTOR_HANDLE * xhandle, MKL_INT * ipar, double * dpar, MKL_INT * stat );

void s_commit_Helmholtz_2D (float * f, const float * bd_ax, const float * bd_bx, const float * bd_ay, const float * bd_by, DFTI_DESCRIPTOR_HANDLE * xhandle, MKL_INT * ipar, float * spar, MKL_INT * stat );
```

```

void d_commit_Helmholtz_3D (double * f, const double * bd_ax, const double * bd_bx,
const double * bd_ay, const double * bd_by, const double * bd_az, const double * bd_bz,
DFTI_DESCRIPTOR_HANDLE * xhandle, DFTI_DESCRIPTOR_HANDLE * yhandle, MKL_INT * ipar,
double * dpar, MKL_INT * stat );

void s_commit_Helmholtz_3D (float * f, const float * bd_ax, const float * bd_bx, const
float * bd_ay, const float * bd_by, const float * bd_az, const float * bd_bz,
DFTI_DESCRIPTOR_HANDLE * xhandle, DFTI_DESCRIPTOR_HANDLE * yhandle, MKL_INT * ipar,
float * spar, MKL_INT * stat );

```

Include Files

- mkl.h

Input Parameters

<i>f</i>	double* for d_commit_Helmholtz_2D/d_commit_Helmholtz_3D, float* for s_commit_Helmholtz_2D/s_commit_Helmholtz_3D. Contains the right-hand side of the problem packed in a single vector: • 2D problem: The size of the vector for the is $(n_x+1)*(n_y+1)$. The value of the right-hand side in the mesh point (i, j) is stored in $f[i+j*(n_x+1)]$. • 3D problem: The size of the vector for the is $(n_x+1)*(n_y+1)*(n_z+1)$. The value of the right-hand side in the mesh point (i, j, k) is stored in $f[i+j*(n_x+1)+k*(n_x+1)*(n_y+1)]$. Note that to solve the Laplace problem, you should set all the elements of the array <i>f</i> to 0. Note also that the array <i>f</i> may be altered by the routine. To preserve the <i>f</i> vector, save it to another memory location.
<i>ipar</i>	MKL_INT array of size 128. Contains integer data to be used by the Fast Helmholtz Solver (for details, refer to ipar).
<i>dpar</i>	double array of size depending on the dimension of the problem: • 2D problem: $5*n_x/2+7$ • 3D problem: $5*(n_x+n_y)/2+9$ Contains double-precision data to be used by the Fast Helmholtz Solver (for details, refer to dpar and spar).
<i>spar</i>	float array of size depending on the dimension of the problem: • 2D problem: $5*n_x/2+7$ • 3D problem: $5*(n_x+n_y)/2+9$ Contains single-precision data to be used by the Fast Helmholtz Solver (for details, refer to dpar and spar).
<i>bd_ax</i>	double* for d_commit_Helmholtz_2D/d_commit_Helmholtz_3D, float* for s_commit_Helmholtz_2D/s_commit_Helmholtz_3D. Contains values of the boundary condition on the leftmost boundary of the domain along the x-axis (for more information, refer to a detailed description of bd_ax).

<i>bd_bx</i>	double* for d_commit_Helmholtz_2D/d_commit_Helmholtz_3D, float* for s_commit_Helmholtz_2D/s_commit_Helmholtz_3D. Contains values of the boundary condition on the rightmost boundary of the domain along the x-axis (for more information, refer to a detailed description of <i>bd_bx</i>).
<i>bd_ay</i>	double* for d_commit_Helmholtz_2D/d_commit_Helmholtz_3D, float* for s_commit_Helmholtz_2D/s_commit_Helmholtz_3D. Contains values of the boundary condition on the leftmost boundary of the domain along the y-axis (for more information, refer to a detailed description of <i>bd_ay</i>).
<i>bd_by</i>	double* for d_commit_Helmholtz_2D/d_commit_Helmholtz_3D, float* for s_commit_Helmholtz_2D/s_commit_Helmholtz_3D. Contains values of the boundary condition on the rightmost boundary of the domain along the y-axis (for more information, refer to a detailed description of <i>bd_by</i>).
<i>bd_az</i>	double* for d_commit_Helmholtz_3D, float* for s_commit_Helmholtz_3D. Used only by ?_commit_Helmholtz_3D. Contains values of the boundary condition on the leftmost boundary of the domain along the z-axis (for more information, refer to a detailed description of <i>bd_az</i>).
<i>bd_bz</i>	double* for d_commit_Helmholtz_3D, float* for s_commit_Helmholtz_3D. Used only by ?_commit_Helmholtz_3D. Contains values of the boundary condition on the rightmost boundary of the domain along the z-axis (for more information, refer to a detailed description of <i>bd_bz</i>).

Output Parameters

<i>f</i>	Contains right-hand side of the problem, possibly altered on output.
<i>ipar</i>	Contains integer data to be used by Fast Helmholtz Solver. Modified on output as explained in ipar .
<i>dpar</i>	Contains double-precision data to be used by Fast Helmholtz Solver. Modified on output as explained in dpar and spar .
<i>spar</i>	Contains single-precision data to be used by Fast Helmholtz Solver. Modified on output as explained in dpar and spar .
<i>xhandle, yhandle</i>	DFTI_DESCRIPTOR_HANDLE*. Data structures used by the Intel MKL FFT interface (for details, refer to section " FFT Functions " in chapter "Fast Fourier Transforms"). <i>yhandle</i> is used only by ?_commit_Helmholtz_3D.
<i>stat</i>	MKL_INT*. Routine completion status, which is also written to <i>ipar</i> [0]. Continue to call other Poisson Solver routines only if the status is 0.

Description

The `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D` routines check the consistency and correctness of the parameters to be passed to the solver routines `?_Helmholtz_2D/?_Helmholtz_3D`. They also initialize the `xhandle` and `yhandle` data structures, `ipar` array, and `dpar` or `spar` array, depending upon the routine precision. Refer to [Common Parameters](#) to find out which particular array elements the `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D` routines initialize and to what values these elements are initialized.

The routines perform only a basic check for correctness and consistency. If you are going to modify parameters of Poisson Solver routines, see [Caveat on Parameter Modifications](#). Unlike `?_init_Helmholtz_2D/?_init_Helmholtz_3D`, you must call the `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D` routines in your code. Values of `ax`, `bx`, `ay`, `by`, `az`, and `bz` are passed to the routines with the `spar/dpar` array, and values of `nx`, `ny`, `nz`, and `BCTYPE` are passed with the `ipar` array.

Return Values

<code>stat= 1</code>	The routine completed without errors but with warnings.
<code>stat= 0</code>	The routine successfully completed the task.
<code>stat= -100</code>	The routine stopped because an error in the input data was found, or the data in the <code>dpar</code> , <code>spar</code> , or <code>ipar</code> array was altered by mistake.
<code>stat= -1000</code>	The routine stopped because of an Intel MKL FFT or TT interface error.
<code>stat= -10000</code>	The routine stopped because the initialization failed to complete or the parameter <code>ipar[0]</code> was altered by mistake.
<code>stat= -99999</code>	The routine failed to complete the task because of a fatal error.

?_Helmholtz_2D/?_Helmholtz_3D

Computes the solution of the 2D/3D Helmholtz problem specified by the parameters.

Syntax

```
void d_Helmholtz_2D (double * f, const double * bd_ax, const double * bd_bx, const
double * bd_ay, const double * bd_by, DFTI_DESCRIPTOR_HANDLE * xhandle, MKL_INT * ipar,
const double * dpar, MKL_INT * stat );

void s_Helmholtz_2D (float * f, const float * bd_ax, const float * bd_bx, const float *
bd_ay, const float * bd_by, DFTI_DESCRIPTOR_HANDLE * xhandle, MKL_INT * ipar, const
float * spar, MKL_INT * stat );

void d_Helmholtz_3D (double * f, const double * bd_ax, const double * bd_bx, const
double * bd_ay, const double * bd_by, const double * bd_az, const double * bd_bz,
DFTI_DESCRIPTOR_HANDLE * xhandle, DFTI_DESCRIPTOR_HANDLE * yhandle, MKL_INT * ipar,
const double * dpar, MKL_INT * stat );

void s_Helmholtz_3D (float * f, const float * bd_ax, const float * bd_bx, const float *
bd_ay, const float * bd_by, const float * bd_az, const float * bd_bz,
DFTI_DESCRIPTOR_HANDLE * xhandle, DFTI_DESCRIPTOR_HANDLE * yhandle, MKL_INT * ipar,
const float * spar, MKL_INT * stat );
```

Include Files

- `mkl.h`

Input Parameters

<code>f</code>	<code>double* for d_Helmholtz_2D/d_Helmholtz_3D,</code> <code>float* for s_Helmholtz_2D/s_Helmholtz_3D.</code> Contains the right-hand side of the problem packed in a single vector and modified by the appropriate <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D</code> routine. Note that an attempt to substitute the original right-hand side vector, which was passed to the <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D</code> routine, at this point results in an incorrect solution. • 2D problem: the size of the vector is $(nx+1)*(ny+1)$. The value of the modified right-hand side in the mesh point (i, j) is stored in <code>f[i+j*(nx+1)]</code>. • 3D problem: the size of the vector is $(nx+1)*(ny+1)*(nz+1)$. The value of the modified right-hand side in the mesh point (i, j, k) is stored in <code>f[i+j*(nx+1)+k*(nx+1)*(ny+1)]</code>.
<code>xhandle, yhandle</code>	<code>DEFTI_DESCRIPTOR_HANDLE*</code>. Data structures used by the Intel MKL FFT interface (for details, refer to section "FFT Functions" in chapter "Fast Fourier Transforms"). <code>yhandle</code> is used only by <code>?_Helmholtz_3D</code>.
<code>ipar</code>	<code>MKL_INT</code> array of size 128. Contains integer data to be used by Fast Helmholtz Solver (for details, refer to <code>ipar</code>).
<code>dpar</code>	<code>double</code> array of size depending on the dimension of the problem: • 2D problem: $5*nx/2+7$ • 3D problem: $5*(nx+ny)/2+9$ Contains double-precision data to be used by Fast Helmholtz Solver (for details, refer to <code>dpar</code> and <code>spar</code>).
<code>spar</code>	<code>float</code> array of size depending on the dimension of the problem: • 2D problem: $5*nx/2+7$ • 3D problem: $5*(nx+ny)/2+9$ Contains single-precision data to be used by Fast Helmholtz Solver (for details, refer to <code>dpar</code> and <code>spar</code>).
<code>bd_ax</code>	<code>double* for d_Helmholtz_2D/d_Helmholtz_3D,</code> <code>float* for s_Helmholtz_2D/s_Helmholtz_3D.</code> Contains values of the boundary condition on the leftmost boundary of the domain along the x-axis (for more information, refer to a detailed description of bd_ax).
<code>bd_bx</code>	<code>double* for d_Helmholtz_2D/d_Helmholtz_3D,</code> <code>float* for s_Helmholtz_2D/s_Helmholtz_3D.</code>

Contains values of the boundary condition on the rightmost boundary of the domain along the x-axis (for more information, refer to [a detailed description of `bd\_bx`](#)).

`bd_ay` double* for d_Helmholtz_2D/d_Helmholtz_3D,
float* for s_Helmholtz_2D/s_Helmholtz_3D.

Contains values of the boundary condition on the leftmost boundary of the domain along the y-axis for more information, refer to [a detailed description of `bd\_ay`](#)).

`bd_by` double* for d_Helmholtz_2D/d_Helmholtz_3D,
float* for s_Helmholtz_2D/s_Helmholtz_3D.

Contains values of the boundary condition on the rightmost boundary of the domain along the y-axis (for more information, refer to [a detailed description of `bd\_by`](#)).

`bd_az` double* for d_Helmholtz_3D,
float* for s_Helmholtz_3D.

Used only by ?_Helmholtz_3D. Contains values of the boundary condition on the leftmost boundary of the domain along the z-axis (for more information, refer to [a detailed description of `bd\_az`](#)).

`bd_bz` double* for d_Helmholtz_3D,
float* for s_Helmholtz_3D.

Used only by ?_Helmholtz_3D. Contains values of the boundary condition on the rightmost boundary of the domain along the z-axis (for more information, refer to [a detailed description of `bd\_bz`](#)).

NOTE

To avoid incorrect computation results, do not change arrays `bd_ax`, `bd_bx`, `bd_ay`, `bd_by`, `bd_az`, `bd_bz` between a call to the `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D` routine and a subsequent call to the appropriate `?_Helmholtz_2D/?_Helmholtz_3D` routine.

Output Parameters

<code>f</code>	On output, contains the approximate solution to the problem packed the same way as the right-hand side of the problem was packed on input.
<code>xhandle, yhandle</code>	Data structures used by the Intel MKL FFT interface. Although the addresses do not change, the structures are modified on output.
<code>ipar</code>	Contains integer data to be used by Fast Helmholtz Solver. Modified on output as explained in ipar .
<code>stat</code>	MKL_INT*. Routine completion status, which is also written to <code>ipar[0]</code> . Continue to call other Poisson Solver routines only if the status is 0.

Description

The `?_Helmholtz_2D/?_Helmholtz_3D` routines compute the approximate solution of the Helmholtz problem defined in the previous calls to the corresponding initialization and commit routines. The solution is computed according to formulas given in the [Poisson Solver Implementation](#) section. The `f` parameter, which initially holds the packed vector of the right-hand side of the problem, is replaced by the computed solution packed in the same way. Values of `ax`, `bx`, `ay`, `by`, `az`, and `bz` are passed to the routines with the `spar/dpar` array, and values of `nx`, `ny`, `nz`, and `BCtype` are passed with the `ipar` array.

Return Values

<code>stat= 1</code>	The routine completed without errors but with some warnings.
<code>stat= 0</code>	The routine successfully completed the task.
<code>stat= -2</code>	The routine stopped because division by zero occurred. It usually happens if the data in the <code>dpar</code> or <code>spar</code> array was altered by mistake.
<code>stat= -3</code>	The routine stopped because the sufficient memory was unavailable for the computations.
<code>stat= -100</code>	The routine stopped because an error in the input data was found or the data in the <code>dpar</code> , <code>spar</code> , or <code>ipar</code> array was altered by mistake.
<code>stat= -1000</code>	The routine stopped because of the Intel MKL FFT or TT interface error.
<code>stat= -10000</code>	The routine stopped because the initialization failed to complete or the parameter <code>ipar[0]</code> was altered by mistake.
<code>stat= -99999</code>	The routine failed to complete the task because of a fatal error.

`free_Helmholtz_2D/free_Helmholtz_3D`

Releases the memory allocated for the data structures used by the FFT interface.

Syntax

```
void free_Helmholtz_2D(DFTI_DESCRIPTOR_HANDLE* xhandle, MKL_INT* ipar, MKL_INT* stat);  
void free_Helmholtz_3D(DFTI_DESCRIPTOR_HANDLE* xhandle, DFTI_DESCRIPTOR_HANDLE* yhandle, MKL_INT* ipar, MKL_INT* stat);
```

Include Files

- `mkh.h`

Input Parameters

<i>xhandle, yhandle</i>	DFTI_DESCRIPTOR_HANDLE*. Data structures used by the Intel MKL FFT interface (for details, refer to section " FFT Functions " in chapter "Fast Fourier Transforms"). The structure <i>yhandle</i> is used only by <code>free_Helmholtz_3D</code> .
<i>ipar</i>	MKL_INT array of size 128. Contains integer data used by Fast Helmholtz Solver (for details, refer to ipar).

Output Parameters

<i>xhandle, yhandle</i>	Data structures used by the Intel MKL FFT interface. Memory allocated for the structures is released on output.
<i>ipar</i>	Contains integer data used by Fast Helmholtz Solver. On output, the status of the routine call is written to <i>ipar[0]</i> .
<i>stat</i>	MKL_INT*. Routine completion status, which is also written to <i>ipar[0]</i> .

Description

The `free_Helmholtz_2D-free_Helmholtz_3D` routine releases the memory used by the *xhandle* and *yhandle* structures, which are needed for calling the Intel MKL FFT functions. To release memory allocated for other parameters, include memory release statements in your code.

Return Values

<i>stat</i> = 0	The routine successfully completed the task.
<i>stat</i> = -1000	The routine stopped because of an Intel MKL FFT or TT interface error.
<i>stat</i> = -99999	The routine failed to complete the task because of a fatal error.

Routines for the Spherical Solver

The section describes Poisson Solver routines for the spherical case, their syntax, parameters, and return values. All flavors of the same routine are described together: single- and double-precision and periodic (having names ending in "p") and non-periodic (having names ending in "np").

These Poisson Solver routines also call the Intel MKL FFT routines (described in section "[FFT Functions](#)" in chapter "Fast Fourier Transforms"), which enhance the performance of the Poisson Solver routines.

[?_init_sph_p/?_init_sph_np](#)

Initializes basic data structures of the periodic and non-periodic Fast Helmholtz Solver on a sphere.

Syntax

```
void d_init_sph_p (const double * ap, const double * at, const double * bp, const
double * bt, const MKL_INT * np, const MKL_INT * nt, const double * q, MKL_INT * ipar,
double * dpar, MKL_INT * stat );
```

```
void s_init_sph_p (const float * ap, const float * at, const float * bp, const float *
bt, const MKL_INT * np, const MKL_INT * nt, const float * q, MKL_INT * ipar, float *
spar, MKL_INT * stat );
```

```
void d_init_sph_np (const double * ap, const double * at, const double * bp, const
double * bt, const MKL_INT * np, const MKL_INT * nt, const double * q, MKL_INT * ipar,
double * dpar, MKL_INT * stat );
```

```
void s_init_sph_np (const float * ap, const float * at, const float * bp, const float *
bt, const MKL_INT * np, const MKL_INT * nt, const float * q, MKL_INT * ipar, float *
spar, MKL_INT * stat );
```

Include Files

- mkl.h

Input Parameters

<i>ap</i>	double* for d_init_sph_p/d_init_sph_np, float* for s_init_sph_p/s_init_sph_np. The coordinate (angle) of the leftmost boundary of the domain along the φ -axis.
<i>bp</i>	double* for d_init_sph_p/d_init_sph_np, float* for s_init_sph_p/s_init_sph_np. The coordinate (angle) of the rightmost boundary of the domain along the φ -axis.
<i>at</i>	double* for d_init_sph_p/d_init_sph_np, float* for s_init_sph_p/s_init_sph_np. The coordinate (angle) of the leftmost boundary of the domain along the θ -axis.
<i>bt</i>	double* for d_init_sph_p/d_init_sph_np, float* for s_init_sph_p/s_init_sph_np. The coordinate (angle) of the rightmost boundary of the domain along the θ -axis.
<i>np</i>	MKL_INT*. The number of mesh intervals along the φ -axis. Must be even in the periodic case.
<i>nt</i>	MKL_INT*. The number of mesh intervals along the θ -axis.
<i>q</i>	double* for d_init_sph_p/d_init_sph_np, float* for s_init_sph_p/s_init_sph_np. The constant Helmholtz coefficient. To solve the Poisson problem, set the value of <i>q</i> to 0.

Output Parameters

<i>ipar</i>	MKL_INT array of size 128. Contains integer data to be used by Fast Helmholtz Solver on a sphere (for details, refer to ipar).

<i>dpar</i>	double array of size $5 \cdot n_p/2 + n_t + 10$. Contains double-precision data to be used by Fast Helmholtz Solver on a sphere (for details, refer to dpar and spar).
<i>spar</i>	float array of size $5 \cdot n_p/2 + n_t + 10$. Contains single-precision data to be used by Fast Helmholtz Solver on a sphere (for details, refer to dpar and spar).
<i>stat</i>	MKL_INT*. Routine completion status, which is also written to <i>ipar</i> [0]. Continue to call other Poisson Solver routines only if the status is 0.

Description

The `?_init_sph_p/?_init_sph_np` routines initialize basic data structures for Poisson Solver computations. All routines invoked after a call to a `?_init_Helmholtz_2D/?_init_Helmholtz_3D` routine use values of the *ipar*, *dpar*, and *spar* array parameters returned by the routine. A detailed description of the array parameters can be found in [Common Parameters](#).

CAUTION

Data structures initialized and created by periodic flavors of the routine cannot be used by non-periodic flavors of any Poisson Solver routines for Helmholtz Solver on a sphere, and vice versa.

You can skip calls to these routines in your code. However, see [Caveat on Parameter Modifications](#) for information on initializing the data structures.

Return Values

<i>stat</i> = 0	The routine successfully completed the task. In general, to proceed with computations, the routine should complete with this <i>stat</i> value.
<i>stat</i> = -99999	The routine failed to complete the task because of fatal error.

?_commit_sph_p/?_commit_sph_np

Checks consistency and correctness of input data and initializes certain data structures required to solve the periodic/non-periodic Helmholtz problem on a sphere.

Syntax

```
void d_commit_sph_p(double* f, DFTI_DESCRIPTOR_HANDLE* handle_s,
DFTI_DESCRIPTOR_HANDLE* handle_c, MKL_INT* ipar, double* dpar, MKL_INT* stat);

void s_commit_sph_p(float* f, DFTI_DESCRIPTOR_HANDLE* handle_s, DFTI_DESCRIPTOR_HANDLE*
handle_c, MKL_INT* ipar, float* spar, MKL_INT* stat);

void d_commit_sph_np(double* f, DFTI_DESCRIPTOR_HANDLE* handle, MKL_INT* ipar, double*
dpar, MKL_INT* stat);

void s_commit_sph_np(float* f, DFTI_DESCRIPTOR_HANDLE* handle, MKL_INT* ipar, float*
spar, MKL_INT* stat);
```

Include Files

- `mk1.h`

Input Parameters

<i>f</i>	double* for <code>d_commit_sph_p/d_commit_sph_np</code> , float* for <code>s_commit_sph_p/s_commit_sph_np</code> . Contains the right-hand side of the problem packed in a single vector. The size of the vector is $(np+1)*(nt+1)$ and value of the right-hand side in the mesh point (i, j) is stored in $f[i+j*(np+1)]$. Note that the array <i>f</i> may be altered by the routine. Save this vector to another memory location if you want to preserve it.
<i>ipar</i>	MKL_INT array of size 128. Contains integer data to be used by the Fast Helmholtz Solver on a sphere (for details, refer to ipar).
<i>dpar</i>	double array of size $5*np/2+nt+10$. Contains double-precision data to be used by the Fast Helmholtz Solver on a sphere (for details, refer to dpar and spar).
<i>spar</i>	float array of size $5*np/2+nt+10$. Contains single-precision data to be used by the Fast Helmholtz Solver on a sphere (for details, refer to dpar and spar).

Output Parameters

<i>f</i>	Contains the right-hand side of the problem, possibly altered on output.
<i>ipar</i>	Contains integer data to be used by the Fast Helmholtz Solver on a sphere. Modified on output as explained in ipar .
<i>dpar</i>	Contains double-precision data to be used by the Fast Helmholtz Solver on a sphere. Modified on output as explained in dpar and spar .
<i>spar</i>	Contains single-precision data to be used by the Fast Helmholtz Solver on a sphere. Modified on output as explained in dpar and spar .
<i>handle_s</i> , <i>handle_c</i> , <i>handle</i>	DFTI_DESCRIPTOR_HANDLE*. Data structures used by the Intel MKL FFT interface (for details, refer to section " FFT Functions " in chapter "Fast Fourier Transforms"). <i>handle_s</i> and <i>handle_c</i> are used only in <code>?_commit_sph_p</code> and <i>handle</i> is used only in <code>?_commit_sph_np</code> .
<i>stat</i>	MKL_INT*. Routine completion status, which is also written to <i>ipar</i> [0]. Continue to call other Poisson Solver routines only if the status is 0.

Description

The `?_commit_sph_p/?_commit_sph_np` routines check consistency and correctness of the parameters to be passed to the solver routines `?_sph_p/?_sph_np`, respectively. They also initialize certain data structures. The routine `?_commit_sph_p` initializes structures *handle_s* and *handle_c*, and `?_commit_sph_np` initializes *handle*. The routines also initialize the *ipar* array and *dpar* or *spar* array, depending upon the routine precision. Refer to [Common Parameters](#) to find out which particular array elements the `?_commit_sph_p/?_commit_sph_np` routines initialize and to what values these elements are initialized.

The routines perform only a basic check for correctness and consistency. If you are going to modify parameters of Poisson Solver routines, see [Caveat on Parameter Modifications](#). Unlike `?_init_sph_p/?_init_sph_np`, you must call the `?_commit_sph_p/?_commit_sph_np` routines. Values of `np` and `nt` are passed to each of the routines with the `ipar` array.

Return Values

<code>stat= 1</code>	The routine completed without errors but with warnings.
<code>stat= 0</code>	The routine successfully completed the task.
<code>stat= -100</code>	The routine stopped because an error in the input data was found or the data in the <code>dpar</code> , <code>spar</code> , or <code>ipar</code> array was altered by mistake.
<code>stat= -1000</code>	The routine stopped because of an Intel MKL FFT or TT interface error.
<code>stat= -10000</code>	The routine stopped because the initialization failed to complete or the parameter <code>ipar[0]</code> was altered by mistake.
<code>stat= -99999</code>	The routine failed to complete the task because of a fatal error.

`?_sph_p/?_sph_np`

Computes the solution of the spherical Helmholtz problem specified by the parameters.

Syntax

```
void d_sph_p(double* f, DFTI_DESCRIPTOR_HANDLE* handle_s, DFTI_DESCRIPTOR_HANDLE* handle_c, MKL_INT* ipar, double* dpar, MKL_INT* stat);
void s_sph_p(float* f, DFTI_DESCRIPTOR_HANDLE* handle_s, DFTI_DESCRIPTOR_HANDLE* handle_c, MKL_INT* ipar, float* spar, MKL_INT* stat);
void d_sph_np(double* f, DFTI_DESCRIPTOR_HANDLE* handle, MKL_INT* ipar, double* dpar, MKL_INT* stat);
void s_sph_np(float* f, DFTI_DESCRIPTOR_HANDLE* handle, MKL_INT* ipar, float* spar, MKL_INT* stat);
```

Include Files

- `mkh.h`

Input Parameters

<code>f</code>	<code>double*</code> for <code>d_sph_p/d_sph_np</code>, <code>float*</code> for <code>s_sph_p/s_sph_np</code>. Contains the right-hand side of the problem packed in a single vector and modified by the appropriate <code>?_commit_sph_p/?_commit_sph_np</code> routine. Note that an attempt to substitute the original right-hand side vector, which was passed to the <code>?_commit_sph_p/?_commit_sph_np</code> routine, at this point results in an incorrect solution.

The size of the vector is $(np+1)*(nt+1)$ and the value of the modified right-hand side in the mesh point (i, j) is stored in $f[i+j*(np+1)]$.

handle_s, *handle_c*,
handle

DFTI_DESCRIPTOR_HANDLE*. Data structures used by Intel MKL FFT interface (for details, refer to section "FFT Functions" in chapter "Fast Fourier Transforms"). *handle_s* and *handle_c* are used only in ?_sph_p and *handle* is used only in ?_sph_np.

ipar

MKL_INT array of size 128. Contains integer data to be used by the Fast Helmholtz Solver on a sphere (for details, refer to [ipar](#)).

dpar

double array of size $5*np/2+nt+10$. Contains double-precision data to be used by the Fast Helmholtz Solver on a sphere (for details, refer to [dpar](#) and [spar](#)).

spar

float array of size $5*np/2+nt+10$. Contains single-precision data to be used by the Fast Helmholtz Solver on a sphere (for details, refer to [dpar](#) and [spar](#)).

Output Parameters

f

On output, contains the approximate solution to the problem packed the same way as the right-hand side of the problem was packed on input.

handle_s, *handle_c*,
handle

Data structures used by the Intel MKL FFT interface.

ipar

Contains integer data to be used by the Fast Helmholtz Solver on a sphere. Modified on output as explained in [ipar](#).

dpar

Contains double-precision data to be used by the Fast Helmholtz Solver on a sphere. Modified on output as explained in [dpar](#) and [spar](#).

spar

Contains single-precision data to be used by the Fast Helmholtz Solver on a sphere. Modified on output as explained in [dpar](#) and [spar](#).

stat

MKL_INT*. Routine completion status, which is also written to *ipar*[0]. Continue to call other Poisson Solver routines only if the status is 0.

Description

The *sph_p*/*sph_np* routines compute the approximate solution on a sphere of the Helmholtz problem defined in the previous calls to the corresponding initialization and commit routines. The solution is computed according to the formulas given in the [Poisson Solver Implementation](#) section. The *f* parameter, which initially holds the packed vector of the right-hand side of the problem, is replaced by the computed solution packed in the same way. Values of *np* and *nt* are passed to each of the routines with the *ipar* array.

Return Values

stat= 1

The routine completed without errors but with warnings.

stat= 0

The routine successfully completed the task.

<code>stat= -2</code>	The routine stopped because division by zero occurred. It usually happens if the data in the <code>dpar</code> or <code>spar</code> array was altered by mistake.
<code>stat= -3</code>	The routine stopped because the memory was insufficient to complete the computations.
<code>stat= -100</code>	The routine stopped because an error in the input data was found or the data in the <code>dpar</code> , <code>spar</code> , or <code>ipar</code> array was altered by mistake.
<code>stat= -1000</code>	The routine stopped because of an Intel MKL FFT or TT interface error.
<code>stat= -10000</code>	The routine stopped because the initialization failed to complete or the parameter <code>ipar[0]</code> was altered by mistake.
<code>stat= -99999</code>	The routine failed to complete the task because of a fatal error.

free_sph_p/free_sph_np

Releases the memory allocated for the data structures used by the FFT interface.

Syntax

```
void free_sph_p(DFTI_DESCRIPTOR_HANDLE* handle_s, DFTI_DESCRIPTOR_HANDLE* handle_c,
MKL_INT* ipar, MKL_INT* stat);

void free_sph_np(DFTI_DESCRIPTOR_HANDLE* handle, MKL_INT* ipar, MKL_INT* stat);
```

Include Files

- `mkl.h`

Input Parameters

<code>handle_s</code> , <code>handle_c</code> , <code>handle</code>	DFTI_DESCRIPTOR_HANDLE*. Data structures used by the Intel MKL FFT interface (for details, refer to section " FFT Functions " in chapter "Fast Fourier Transforms"). The structures <code>handle_s</code> and <code>handle_c</code> are used only in <code>free_sph_p</code> , and <code>handle</code> is used only in <code>free_sph_np</code> .
<code>ipar</code>	MKL_INT array of size 128. Contains integer data to be used by Fast Helmholtz Solver on a sphere (for details, refer to ipar).

Output Parameters

<code>handle_s</code> , <code>handle_c</code> , <code>handle</code>	Data structures used by the Intel MKL FFT interface. Memory allocated for the structures is released on output.
<code>ipar</code>	Contains integer data to be used by Fast Helmholtz Solver on a sphere. On output, the status of the routine call is written to <code>ipar[0]</code> .
<code>stat</code>	MKL_INT*. Routine completion status, which is also written to <code>ipar[0]</code> .

Description

The `free_sph_p/free_sph_np` routine releases the memory used by the `handle_s`, `handle_c` or `handle` structures, needed for calling the Intel MKL FFT functions. To release memory allocated for other parameters, include memory release statements in your code.

Return Values

<code>stat= 0</code>	The routine successfully completed the task.
<code>stat= -1000</code>	The routine stopped because of an Intel MKL FFT or TT interface error.
<code>stat= -99999</code>	The routine failed to complete the task because of a fatal error.

Common Parameters

ipar

`ipar` MKL_INT array of size 128, holds integer data needed for Fast Helmholtz Solver (both for Cartesian and spherical coordinate systems). Its elements are described in [Table "Elements of the ipar Array"](#):

NOTE

Initial values are assigned to the array parameters by the appropriate `?_init_Helmholtz_2D/?_init_Helmholtz_3D/?_init_sph_p/?_init_sph_np` and `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D/?_commit_sph_p/?_commit_sph_np` routines.

Elements of the ipar Array

Index	Description
0	Contains status value of the last Poisson Solver routine called. In general, it should be 0 on exit from a routine to proceed with the Fast Helmholtz Solver. The element has no predefined values. This element can also be used to inform the <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D/?_commit_sph_p/?_commit_sph_np</code> routines of how the Commit step of the computation should be carried out (see Figure "Typical Order of Invoking Poisson Solver Routines"). A non-zero value of <code>ipar[0]</code> with decimal representation $\overline{abc} = 100a + 10b + c$ $= 100a + 10b + c$, where each of a , b , and c is equal to 0 or 9, indicates that some parts of the Commit step should be omitted. • If $c=9$, the routine omits checking of parameters and initialization of the data structures. • If $b=9$, • In the Cartesian case, the routine omits the adjustment of the right-hand side vector f to the Neumann boundary condition (multiplication of boundary values by 0.5 as well as incorporation of the boundary function g) and/or the Dirichlet boundary condition (setting boundary values to 0 as well as incorporation of the boundary function G). • For the Helmholtz solver on a sphere, the routine omits computation of the spherical weights for the <code>dpar/spar</code> array.

Index	Description
	- If $a=9$, the routine omits the normalization of the right-hand side vector $\mathbf{f}$. Depending on the solver, the normalization means: 2D Cartesian case: multiplication by h_y^2, where h_y is the mesh size in the y direction (for details, see Poisson Solver Implementation). 3D (Cartesian) case: multiplication by h_z^2, where h_z is the mesh size in the z direction. - Helmholtz solver on a sphere: multiplication by h_θ^2, where h_θ is the mesh size in the θ direction (for details, see Poisson Solver Implementation). Using <code>ipar[0]</code> you can adjust the routine to your needs and improve efficiency in solving multiple Helmholtz problems that differ only in the right-hand side. You must be cautious when using this method, because any misunderstanding of the commit process may cause incorrect results or program failure (see also Caveat on Parameter Modifications).
1	Contains error messaging options: <code>ipar[1]=-1</code> indicates that all error messages are printed to the <code>MKL_Poisson_Library_log.txt</code> file in the folder from which the routine is called. If the file does not exist, the routine tries to create it. If the attempt fails, the routine prints information that the file cannot be created to the standard output device (usually, screen). <code>ipar[1]=0</code> indicates that no error messages will be printed. <code>ipar[1]=1</code> is the default value. It indicates that all error messages are printed to the standard output device. In case of errors, the <code>stat</code> parameter contains a non-zero value on exit from a routine regardless of the <code>ipar[1]</code> setting.
2	Contains warning messaging options: <code>ipar[2]=-1</code> indicates that all warning messages are printed to the <code>MKL_Poisson_Library_log.txt</code> file in the directory from which the routine is called. If the file does not exist, the routine tries to create it. If the attempt fails, the routine prints information that the file cannot be created to the standard output device. <code>ipar[2]=0</code> indicates that no warning messages will be printed. <code>ipar[2]=1</code> is the default value. It indicates that all warning messages are printed to the standard output device. In case of warnings, the <code>stat</code> parameter contains a non-zero value on exit from a routine regardless of the <code>ipar[2]</code> setting.
3	Unused.
Parameters 4 through 9 are used only in the Cartesian case.	
4	Takes this value: 2, if <code>BCTYPE[0]='P'</code> 1, if <code>BCTYPE[0]='N'</code> 0, if <code>BCTYPE[0]='D'</code> -1, otherwise
5	Takes this value: 2, if <code>BCTYPE[1]='P'</code> 1, if <code>BCTYPE[1]='N'</code> 0, if <code>BCTYPE[1]='D'</code> -1, otherwise
6	Takes this value:

Index	Description
	• 2, if $Btype[2]='P'$ • 1, if $Btype[2]='N'$ • 0, if $Btype[2]='D'$ • -1, otherwise
7	Takes this value: • 2, if $Btype[3]='P'$ • 1, if $Btype[3]='N'$ • 0, if $Btype[3]='D'$ • -1, otherwise
8	Takes this value: • 2, if $Btype[4]='P'$ • 1, if $Btype[4]='N'$ • 0, if $Btype[4]='D'$ • -1, otherwise
9	Takes this value: • 2, if $Btype[5]='P'$ • 1, if $Btype[5]='N'$ • 0, if $Btype[5]='D'$ • -1, otherwise
10	Takes the value of • nx, that is, the number of intervals along the x-axis, in the Cartesian case. • np, that is, the number of intervals along the ϕ-axis, in the spherical case.
11	Takes the value of • ny, that is, the number of intervals along the y-axis, in the Cartesian case • nt, that is, the number of intervals along the θ-axis, in the spherical case.
12	Takes the value of nz , the number of intervals along the z-axis. This parameter is used only in the 3D case (Cartesian).
13	Has the value of 6, which specifies the internal partitioning of the $dpar/spar$ array.
14	Takes the value of $ipar[13]+ipar[10]+1$, which specifies the internal partitioning of the $dpar/spar$ array.

The values of $ipar[15] - ipar[20]$ depend on the dimension of the problem for the Cartesian solver or on whether the solver on a sphere is periodic.

	Cartesian Solver		Spherical Solver	
	2D case	3D case	Periodic case	Non-periodic case
15	Unused	Takes the value of $ipar[14]+1$, which specifies the internal partitioning of the $dpar/spar$ array.		
16	Unused	Takes the value of $ipar[14]+ipar[11]+1$, which specifies the internal partitioning of the $dpar/spar$ array.		

Index	Description			
17	Takes the value of $ipar[14]+1$, which specifies the internal partitioning of the <i>dpar/spar</i> array. Takes the value of $ipar[16]+1$, which specifies the internal partitioning of the <i>dpar/spar</i> array.			
18	Takes the value of $ipar[14]+3*ipar[10]/2+1$, which specifies the internal partitioning of the <i>dpar/spar</i> array.	Takes the value of $ipar[16]+3*ipar[10]/2+1$, which specifies the internal partitioning of the <i>dpar/spar</i> array.	Takes the value of $ipar[16]+3*ipar[10]/4+1$, which specifies the internal partitioning of the <i>dpar/spar</i> array.	Takes the value of $ipar[16]+3*ipar[10]/2+1$, which specifies the internal partitioning of the <i>dpar/spar</i> array.
19	Takes the value of $ipar[18]+1$, which specifies the internal partitioning of the <i>dpar/spar</i> array.	Takes the value of $ipar[18]+1$, which specifies the internal partitioning of the <i>dpar/spar</i> array. Unused		
20	Takes the value of $ipar[19]+3*ipar[12]/4$, which specifies the internal partitioning of the <i>dpar/spar</i> array.	Takes the value of $ipar[18]+3*ipar[11]/2+1$, which specifies the internal partitioning of the <i>dpar/spar</i> array.	Takes the value of $ipar[18]+3*ipar[10]/4+1$, which specifies the internal partitioning of the <i>dpar/spar</i> array.	Unused
The values of $ipar[21] - ipar[119]$ are assigned regardless of the dimension of the problem for the Cartesian solver or of whether the solver on a sphere is periodic.				
21	Contains message style options. Specifically: $ipar[21]=1$ (default) indicates that Poisson Solver routines print the messages in C-style notations.			
22	Contains the number of OpenMP threads to be used for computations in a multithreaded environment. The default value is 1 in the serial mode, and the result returned by the <code>mk1_get_max_threads</code> function otherwise.			
23	Takes the value of $ipar[18]+1$, which specifies the internal partitioning of the <i>dpar/spar</i> array in the periodic Cartesian case.			
24	Takes the value of $ipar[23]+3*ipar[12]/4$, which specifies the internal partitioning of the <i>dpar/spar</i> array in the periodic Cartesian case.			
25	Takes the value of $ipar[20]+1$, which specifies the internal partitioning of the <i>dpar/spar</i> array in the periodic 3D Cartesian case.			
26	Takes the value of $ipar[25]+3*ipar[13]/4$, which specifies the internal partitioning of the <i>dpar/spar</i> array in the periodic 3D Cartesian case.			
27 through 39	Unused.			
40 through 59	Contain the first twenty elements of the <i>ipar</i> array of the first Trigonometric Transform that the solver uses. (For details, see Common Parameters in the "Trigonometric Transform Routines" section.)			

Index	Description
60 through 79	Contain the first twenty elements of the <i>ipar</i> array of the second Trigonometric Transform that the 3D Cartesian and periodic spherical solvers use. (For details, see Common Parameters in the "Trigonometric Transform Routines" section.)
80 through 99	Contain the first twenty elements of the <i>ipar</i> array of the third Trigonometric Transform that the solver uses in case of periodic boundary conditions along the <i>x</i> -axis. (For details, see Common Parameters in the "Trigonometric Transform Routines" section.)
100 through 119	Contain the first twenty elements of the <i>ipar</i> array of the fourth Trigonometric Transform used by periodic spherical solvers and 3D Cartesian solvers with periodic boundary conditions along the <i>y</i> -axis. (For details, see Common Parameters in the "Trigonometric Transform Routines" section.)

NOTE

While you can declare the *ipar* array as `MKL_INT ipar[120]`, for future compatibility you should declare *ipar* as `MKL_INT ipar[128]`.

dpar and spar

Arrays *dpar* and *spar* are the same except in the data precision:

dpar

Holds data needed for double-precision Fast Helmholtz Solver computations.

- For the Cartesian solver, double array of size $5 \times n_x/2 + 7$ in the 2D case or $5 \times (n_x + n_y)/2 + 9$ in the 3D case; initialized in the `d_init_Helmholtz_2D/d_init_Helmholtz_3D` and `d_commit_Helmholtz_2D/d_commit_Helmholtz_3D` routines.
- For the spherical solver, double array of size $5 \times n_p/2 + n_t + 10$; initialized in the `d_init_sph_p/d_init_sph_np` and `d_commit_sph_p/d_commit_sph_np` routines.

spar

Holds data needed for single-precision Fast Helmholtz Solver computations.

- For the Cartesian solver, float array of size $5 \times n_x/2 + 7$ in the 2D case or $5 \times (n_x + n_y)/2 + 9$ in the 3D case; initialized in the `s_init_Helmholtz_2D/s_init_Helmholtz_3D` and `s_commit_Helmholtz_2D/s_commit_Helmholtz_3D` routines.
- For the spherical solver, float array of size $5 \times n_p/2 + n_t + 10$; initialized in the `s_init_sph_p/s_init_sph_np` and `s_commit_sph_p/s_commit_sph_np` routines.

Because *dpar* and *spar* have similar elements in each position, the elements are described together in [Table "Elements of the dpar and spar Arrays"](#):

Elements of the dpar and spar Arrays

Index	Description
0	In the Cartesian case, contains the length of the interval along the <i>x</i>-axis right after a call to the <code>?_init_Helmholtz_2D/?_init_Helmholtz_3D</code> routine or the mesh size h_x in the <i>x</i> direction (for details, see Poisson Solver Implementation) after a call to the <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D</code> routine. In the spherical case, contains the length of the interval along the ϕ-axis right after a call to the <code>?_init_sph_p/?_init_sph_np</code> routine or the mesh size h_ϕ in the ϕ direction (for details, see Poisson Solver Implementation) after a call to the <code>?_commit_sph_p/?_commit_sph_np</code> routine.

Index	Description
1	In the Cartesian case, contains the length of the interval along the y-axis right after a call to the <code>?_init_Helmholtz_2D/?_init_Helmholtz_3D</code> routine or the mesh size h_y in the y direction (for details, see Poisson Solver Implementation) after a call to the <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D</code> routine. In the spherical case, contains the length of the interval along the θ-axis right after a call to the <code>?_init_sph_p/?_init_sph_np</code> routine or the mesh size h_θ in the θ direction (for details, see Poisson Solver Implementation) after a call to the <code>?_commit_sph_p/?_commit_sph_np</code> routine.
2	In the Cartesian case, contains the length of the interval along the z-axis right after a call to the <code>?_init_Helmholtz_2D/?_init_Helmholtz_3D</code> routine or the mesh size h_z in the z direction (for details, see Poisson Solver Implementation) after a call to the <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D</code> routine. In the Cartesian solver, this parameter is used only in the 3D case. In the spherical solver, contains the coordinate of the leftmost boundary along the θ-axis after a call to the <code>?_init_sph_p/?_init_sph_np</code> routine.
3	Contains the value of the coefficient q after a call to the <code>?_init_Helmholtz_2D/?_init_Helmholtz_3D/?_init_sph_p/?_init_sph_np</code> routine.
4	Contains the tolerance parameter after a call to the <code>?_init_Helmholtz_2D/?_init_Helmholtz_3D/?_init_sph_p/?_init_sph_np</code> routine. - In the Cartesian case, this value is used only for the pure Neumann boundary conditions (<code>BCTYPE="NNNN"</code> in the 2D case; <code>BCTYPE="NNNNNN"</code> in the 3D case). This is a special case, because the right-hand side of the problem cannot be arbitrary if the coefficient q is zero. The Poisson Solver verifies that the classical solution exists (up to rounding errors) using this tolerance. In any case, the Poisson Solver computes the normal solution, that is, the solution that has the minimal Euclidean norm of residual. Nevertheless, the <code>?_Helmholtz_2D/?_Helmholtz_3D</code> routine informs you that the solution may not exist in a classical sense (up to rounding errors). - In the spherical case, the value is used for the special case of a periodic problem on the entire sphere. This special case is similar to the Cartesian case with pure Neumann boundary conditions. Here the Poisson Solver computes the normal solution as well. The parameter is also used to detect whether the problem is periodic up to rounding errors. The default value for this parameter is $1.0\text{E-}10$ in case of double-precision computations or $1.0\text{E-}4$ in case of single-precision computations. You can increase the value of the tolerance, for instance, to avoid the warnings that may appear.
<code>ipar[13]-1</code> through <code>ipar[14]-1</code>	In the Cartesian case, contain the spectrum of the one-dimensional (1D) problem along the x-axis after a call to the <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D</code> routine. In the spherical case, contains the spectrum of the 1D problem along the ϕ-axis after a call to the <code>?_commit_sph_p/?_commit_sph_np</code> routine.
<code>ipar[15]-1</code> through <code>ipar[16]-1</code>	In the Cartesian case, contain the spectrum of the 1D problem along the y-axis after a call to the <code>?_commit_Helmholtz_3D</code> routine. These elements are used only in the 3D case. In the spherical case, contains the spherical weights after a call to the <code>?_commit_sph_p/?_commit_sph_np</code> routine.
<code>ipar[17]-1</code> through <code>ipar[18]-1</code>	Take the values of the (staggered) sine/cosine in the mesh points: along the x-axis after a call to the <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D</code> routine for a Cartesian solver

Index	Description
	along the ϕ-axis after a call to the <code>?_commit_sph_p/?_commit_sph_np</code> routine for a spherical solver.
<i>ipar</i> [19]-1 through <i>ipar</i> [20]-1	Take the values of the (staggered) sine/cosine in the mesh points: - along the y-axis after a call to the <code>?_commit_Helmholtz_3D</code> routine for a Cartesian 3D solver - along the ϕ-axis after a call to the <code>?_commit_sph_p</code> routine for a spherical periodic solver. These elements are not used in the 2D Cartesian case and in the non-periodic spherical case.
<i>ipar</i> [23]-1 through <i>ipar</i> [24]-1	Take the values of the (staggered) sine/cosine in the mesh points along the x-axis after a call to the <code>?_commit_Helmholtz_2D/?_commit_Helmholtz_3D</code> routine. These elements are used only in the periodic Cartesian case.
<i>ipar</i> [25]-1 through <i>ipar</i> [26]-1	Take the values of the (staggered) sine/cosine in the mesh points along the x-axis after a call to the <code>?_commit_Helmholtz_3D</code> routine. These elements are used only in the periodic 3D Cartesian case.

NOTE

You may define the array size depending upon the type of the problem to solve.

Caveat on Parameter Modifications

Flexibility of the Poisson Solver interface enables you to skip calls to the `?_init_Helmholtz_2D/?_init_Helmholtz_3D/?_init_sph_p/?_init_sph_np` routine and to initialize the basic data structures explicitly in your code. You may also need to modify contents of the *ipar*, *dpar*, and *spar* arrays after initialization. When doing so, provide correct and consistent data in the arrays. Mistakenly altered arrays cause errors or incorrect results. You can perform a basic check for correctness and consistency of parameters by calling the `?_commit_Helmholtz_2D/?_commit_Helmholtz_3D` routine; however, this does not ensure the correct solution but only reduces the chance of errors or wrong results.

NOTE

To supply correct and consistent parameters to Poisson Solver routines, you should have considerable experience in using the Poisson Solver interface and good understanding of the solution process, as well as elements contained in the *ipar*, *spar*, and *dpar* arrays and dependencies between values of these elements.

In rare occurrences when you fail in tuning parameters for the Fast Helmholtz Solver, refer for technical support at <http://www.intel.com/software/products/support/>.

WARNING

The only way that ensures a proper solution of a Helmholtz problem is to follow a typical sequence of invoking the routines and not change the default set of parameters. So, avoid modifications of *ipar*, *dpar*, and *spar* arrays unless it is necessary.

Parameters That Define Boundary Conditions

Poisson Solver routines for the Cartesian solver use the following common parameters to define the boundary conditions.

Parameters to Define Boundary Conditions for the Cartesian Solver

Parameter	Description
<code>bd_ax</code>	double* for <code>d_commit_Helmholtz_2D/d_commit_Helmholtz_3D</code> and <code>d_Helmholtz_2D/d_Helmholtz_3D</code>, float* for <code>s_commit_Helmholtz_2D/s_commit_Helmholtz_3D</code> and <code>s_Helmholtz_2D/s_Helmholtz_3D</code>. Contains values of the boundary condition on the leftmost boundary of the domain along the x-axis. 2D problem: the size of the array is n_y+1. Its contents depend on the boundary conditions as follows: - Dirichlet boundary condition (value of <code>BCtype[0]</code> is 'D'): values of the function $G(ax, y_j)$, $j=0, \dots, n_y$. - Neumann boundary condition (value of <code>BCtype[0]</code> is 'N'): values of the function $g(ax, y_j)$, $j=0, \dots, n_y$. The value corresponding to the index j is placed in <code>bd_ax[j]</code>. 3D problem: the size of the array is $(n_y+1)*(n_z+1)$. Its contents depend on the boundary conditions as follows: - Dirichlet boundary condition (value of <code>BCtype[0]</code> is 'D'): values of the function $G(ax, y_j, z_k)$, $j=0, \dots, n_y, k=0, \dots, n_z$. - Neumann boundary condition (value of <code>BCtype[0]</code> is 'N'): the values of the function $g(ax, y_j, z_k)$, $j=0, \dots, n_y, k=0, \dots, n_z$. The values are packed in the array so that the value corresponding to indices (j, k) is placed in <code>bd_ax[j+k*(n_y+1)]</code>. For periodic boundary conditions (the value of <code>BCtype[0]</code> is 'P'), this parameter is not used, so it can accept a dummy pointer.
<code>bd_bx</code>	double* for <code>d_commit_Helmholtz_2D/d_commit_Helmholtz_3D</code> and <code>d_Helmholtz_2D/d_Helmholtz_3D</code>, float* for <code>s_commit_Helmholtz_2D/s_commit_Helmholtz_3D</code> and <code>s_Helmholtz_2D/s_Helmholtz_3D</code>. Contains values of the boundary condition on the rightmost boundary of the domain along the x-axis. 2D problem: the size of the array is n_y+1. Its contents depend on the boundary conditions as follows: - Dirichlet boundary condition (value of <code>BCtype[1]</code> is 'D'): values of the function $G(bx, y_j)$, $j=0, \dots, n_y$. - Neumann boundary condition (value of <code>BCtype[1]</code> is 'N'): values of the function $g(bx, y_j)$, $j=0, \dots, n_y$. The value corresponding to the index j is placed in <code>bd_bx[j]</code>. 3D problem: the size of the array is $(n_y+1)*(n_z+1)$. Its contents depend on the boundary conditions as follows: - Dirichlet boundary condition (value of <code>BCtype[1]</code> is 'D'): values of the function $G(bx, y_j, z_k)$, $j=0, \dots, n_y, k=0, \dots, n_z$. - Neumann boundary condition (value of <code>BCtype[1]</code> is 'N'): values of the function $g(bx, y_j, z_k)$, $j=0, \dots, n_y, k=0, \dots, n_z$. The values are packed in the array so that the value corresponding to indices (j, k) is placed in <code>bd_bx[j+k*(n_y+1)]</code>.

Parameter	Description
	For periodic boundary conditions (the value of <i>BCtype</i> [1] is 'P'), this parameter is not used, so it can accept a dummy pointer.
<i>bd_ay</i>	double* for <i>d_commit_Helmholtz_2D</i>/<i>d_commit_Helmholtz_3D</i> and <i>d_Helmholtz_2D</i>/<i>d_Helmholtz_3D</i>, float* for <i>s_commit_Helmholtz_2D</i>/<i>s_commit_Helmholtz_3D</i> and <i>s_Helmholtz_2D</i>/<i>s_Helmholtz_3D</i>. Contains values of the boundary condition on the leftmost boundary of the domain along the <i>y</i>-axis. 2D problem: the size of the array is <i>nx</i>+1. Its contents depend on the boundary conditions as follows: - Dirichlet boundary condition (value of <i>BCtype</i>[2] is 'D'): values of the function $G(x_i, ay)$, $i=0, \dots, nx$. - Neumann boundary condition (value of <i>BCtype</i>[2] is 'N'): values of the function $g(x_i, ay)$, $i=0, \dots, nx$. The value corresponding to the index <i>i</i> is placed in <i>bd_ay</i>[<i>i</i>]. 3D problem: the size of the array is (<i>nx</i>+1)*(<i>nz</i>+1). Its contents depend on the boundary conditions as follows: - Dirichlet boundary condition (value of <i>BCtype</i>[2] is 'D'): values of the function $G(x_i, ay, z_k)$, $i=0, \dots, nx$, $k=0, \dots, nz$. - Neumann boundary condition (value of <i>BCtype</i>[2] is 'N'): values of the function $g(x_i, ay, z_k)$, $i=0, \dots, nx$, $k=0, \dots, nz$. The values are packed in the array so that the value corresponding to indices (<i>i</i>, <i>k</i>) is placed in <i>bd_ay</i>[<i>i</i>+<i>k</i>*(<i>nx</i>+1)]. For periodic boundary conditions (the value of <i>BCtype</i>[2] is 'P'), this parameter is not used, so it can accept a dummy pointer.
<i>bd_by</i>	double* for <i>d_commit_Helmholtz_2D</i>/<i>d_commit_Helmholtz_3D</i> and <i>d_Helmholtz_2D</i>/<i>d_Helmholtz_3D</i>, float* for <i>s_commit_Helmholtz_2D</i>/<i>s_commit_Helmholtz_3D</i> and <i>s_Helmholtz_2D</i>/<i>s_Helmholtz_3D</i>. Contains values of the boundary condition on the rightmost boundary of the domain along the <i>y</i>-axis. 2D problem: the size of the array is <i>nx</i>+1. Its contents depend on the boundary conditions as follows: - Dirichlet boundary condition (value of <i>BCtype</i>[3] is 'D'): values of the function $G(x_i, by)$, $i=0, \dots, nx$. - Neumann boundary condition (value of <i>BCtype</i>[3] is 'N'): values of the function $g(x_i, by)$, $i=0, \dots, nx$. The value corresponding to the index <i>i</i> is placed in <i>bd_by</i>[<i>i</i>]. 3D problem: the size of the array is (<i>nx</i>+1)*(<i>nz</i>+1). Its contents depend on the boundary conditions as follows: - Dirichlet boundary condition (value of <i>BCtype</i>[3] is 'D'): values of the function $G(x_i, by, z_k)$, $i=0, \dots, nx$, $k=0, \dots, nz$. - Neumann boundary condition (value of <i>BCtype</i>[3] is 'N'): values of the function $g(x_i, by, z_k)$, $i=0, \dots, nx$, $k=0, \dots, nz$. The values are packed in the array so that the value corresponding to indices (<i>i</i>, <i>k</i>) is placed in <i>bd_by</i>[<i>i</i>+<i>k</i>*(<i>nx</i>+1)].

Parameter	Description
	For periodic boundary conditions (the value of <i>BCtype</i> [3] is 'P'), this parameter is not used, so it can accept a dummy pointer.
<i>bd_az</i>	double* for <i>d_commit_Helmholtz_3D</i> and <i>d_Helmholtz_3D</i>, float* for <i>s_commit_Helmholtz_3D</i> and <i>s_Helmholtz_3D</i>. Used only by <i>?_commit_Helmholtz_3D</i> and <i>?_Helmholtz_3D</i>. Contains values of the boundary condition on the leftmost boundary of the domain along the z-axis. The size of the array is $(n_x+1)*(n_y+1)$. Its contents depend on the boundary conditions as follows: • Dirichlet boundary condition (value of <i>BCtype</i>[4] is 'D'): values of the function $G(x_i, y_j, az)$, $i=0, \dots, n_x, j=0, \dots, n_y$. • Neumann boundary condition (value of <i>BCtype</i>[4] is 'N'): values of the function $g(x_i, y_j, az)$, $i=0, \dots, n_x, j=0, \dots, n_y$. The values are packed in the array so that the value corresponding to indices (i, j) is placed in <i>bd_az</i>[$i+j*(n_x+1)$]. For periodic boundary conditions (the value of <i>BCtype</i>[4] is 'P'), this parameter is not used, so it can accept a dummy pointer.
<i>bd_bz</i>	double* for <i>d_commit_Helmholtz_3D</i> and <i>d_Helmholtz_3D</i>, float* for <i>s_commit_Helmholtz_3D</i> and <i>s_Helmholtz_3D</i>. Used only by <i>?_commit_Helmholtz_3D</i> and <i>?_Helmholtz_3D</i>. Contains values of the boundary condition on the rightmost boundary of the domain along the z-axis. The size of the array is $(n_x+1)*(n_y+1)$. Its contents depend on the boundary conditions as follows: • Dirichlet boundary condition (value of <i>BCtype</i>[5] is 'D'): values of the function $G(x_i, y_j, bz)$, $i=0, \dots, n_x, j=0, \dots, n_y$. • Neumann boundary condition (value of <i>BCtype</i>[5] is 'N'): values of the function $g(x_i, y_j, bz)$, $i=0, \dots, n_x, j=0, \dots, n_y$. The values are packed in the array so that the value corresponding to indices (i, j) is placed in <i>bd_bz</i>[$i+j*(n_x+1)$]. For periodic boundary conditions (the value of <i>BCtype</i>[5] is 'P'), this parameter is not used, so it can accept a dummy pointer.

Implementation Details

Several aspects of the Intel MKL Poisson Solver interface are platform-specific and language-specific. To promote portability of the Intel MKL Poisson Solver interface across platforms and ease of use across different languages, Intel MKL provides you with the Poisson Solver language-specific header file to include in your code:

- *mkc_poisson.h*, to be used together with *mkc_dfti.h*.

NOTE

- Use of the Intel MKL Poisson Solver software without including the above language-specific header files is not supported.

Header File

The header file defines the function prototypes for the Cartesian and spherical solver available in specific function descriptions.

Nonlinear Optimization Problem Solvers

13

Intel® Math Kernel Library (Intel® MKL) provides tools for solving nonlinear least squares problems using the Trust-Region (TR) algorithms. The solver routines are grouped according to their purpose as follows:

- [Nonlinear Least Squares Problem without Constraints](#)
- [Nonlinear Least Squares Problem with Linear \(Boundary\) Constraints](#)
- [Jacobian Matrix Calculation Routines](#)

For more information on the key concepts required to understand the use of the Intel MKL nonlinear least squares problem solver routines, see [\[Conn00\]](#).

Organization and Implementation

The Intel MKL solver routines for nonlinear least squares problems use reverse communication interfaces (RCI). That means you need to provide the solver with information required for the iteration process, for example, the corresponding Jacobian matrix, or values of the objective function. RCI removes the dependency of the solver on specific implementation of the operations. However, it does require that you organize a computational loop.

Typical order for invoking RCI solver routines

The nonlinear least squares problem solver routines, or Trust-Region (TR) solvers, are implemented with threading support. You can manage the threads using [Threading Control Functions](#). The TR solvers use BLAS and LAPACK routines, and offer the same parallelism as those domains. The `?jacobi` and `?jacobix` routines of Jacobi matrix calculations are parallel. These routines (`?jacobi` and `?jacobix`) make calls to the user-supplied functions with different `x` parameters for multiple threads.

Memory Allocation and Handles

To make the TR solver routines easy to use, you are not required to allocate temporary working storage. The solver allocates any required memory. To allow multiple users to access the solver simultaneously, the solver keeps track of the storage allocated for a particular application by using a data object called a *handle*. Each TR solver routine creates, uses, or deletes a handle. To declare a handle, include `mk1.h`.

Declare a handle as one of the following:

```
#include "mkl.h"
__TRNSP_HANDLE_t handle;
```

or

```
__TRNSPBC_HANDLE_t handle;
```

The first declaration is used for nonlinear least squares problems without boundary constraints, and the second is used for nonlinear least squares problems with boundary constraints.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Routine Naming Conventions

The TR routine names have the following structure:

```
<character><name>_<action>( )
```

where

- *<character>* indicates the data type:

s	float
d	double

- *<name>* indicates the task type:

trnlspl	nonlinear least squares problem without constraints
trnlsplbc	nonlinear least squares problem with boundary constraints
jacobi	computation of the Jacobian matrix using central differences

- *<action>* indicates an action on the task:

init	initializes the solver
check	checks correctness of the input parameters
solve	solves the problem
get	retrieves the number of iterations, the stop criterion, the initial residual, and the final residual
delete	releases the allocated data

Nonlinear Least Squares Problem without Constraints

The nonlinear least squares problem without constraints can be described as follows:

$$\min_{x \in R^n} \|F(x)\|_2^2 = \min_{x \in R^n} \|y - f(x)\|_2^2, y \in R^m, x \in R^n, f: R^n \rightarrow R^m, m \geq n,$$

where

$F(x) : R^n \rightarrow R^m$ is a twice differentiable function in R^n .

Solving a nonlinear least squares problem means searching for the best approximation to the vector y with the model function $f_i(x)$ and nonlinear variables x . The best approximation means that the sum of squares of residuals $y_i - f_i(x)$ is the minimum.

See usage examples in the `examples\solverc\source` folder of your Intel MKL directory. Specifically, see `ex_nlsqp_c.c`.

RCI TR Routines

Routine Name	Operation
<code>?trnlsqp_init</code>	Initializes the solver.
<code>?trnlsqp_check</code>	Checks correctness of the input parameters.
<code>?trnlsqp_solve</code>	Solves a nonlinear least squares problem using the Trust-Region algorithm.
<code>?trnlsqp_get</code>	Retrieves the number of iterations, stop criterion, initial residual, and final residual.
<code>?trnlsqp_delete</code>	Releases allocated data.

?trnlsqp_init

Initializes the solver of a nonlinear least squares problem.

Syntax

```
MKL_INT strnlsqp_init (_TRNSP_HANDLE_t* &handle, const MKL_INT* &n, const MKL_INT* &m,
const float* x, const float* &eps, const MKL_INT* &iter1, const MKL_INT* &iter2, const
float* &rs);
```

```
MKL_INT dtrnlsqp_init (_TRNSP_HANDLE_t* &handle, MKL_INT* &n, const MKL_INT* &m, const
double* x, const double* &eps, const MKL_INT* &iter1, const MKL_INT* &iter2, const
double* &rs);
```

Include Files

- `mkl.h`

Description

The `?trnlsqp_init` routine initializes the solver.

After initialization, all subsequent invocations of the `?trnlsqp_solve` routine should use the values of the handle returned by `?trnlsqp_init`.

The `eps` array contains a number indicating the stopping criteria:

<code>eps</code> Value	Description
0	$\Delta < eps[0]$

<i>eps</i> Value	Description
1	$ F(x) _2 < eps[1]$
2	The Jacobian matrix is singular. $ J(x)_{[m*(j-1)...m*j-1]} _2 < eps[2], j = 1, \dots, n$
3	$ s _2 < eps[3]$
4	$ F(x) _2 - F(x) - J(x)s _2 < eps[4]$
5	The trial step precision. If $eps[5] = 0$, then the trial step meets the required precision ($\leq 1.0 \cdot 10^{-10}$).

Note:

- $J(x)$ is the Jacobian matrix.
- Δ is the trust-region area.
- $F(x)$ is the value of the functional.
- s is the trial step.

Input Parameters

<i>n</i>	Length of x .
<i>m</i>	Length of $F(x)$.
<i>x</i>	Array of size n . Initial guess.
<i>eps</i>	Array of size 6; contains stopping criteria. See the values in the Description section.
<i>iter1</i>	Specifies the maximum number of iterations.
<i>iter2</i>	Specifies the maximum number of iterations of trial step calculation.
<i>rs</i>	Definition of initial size of the trust region (boundary of the trial step). The recommend minimum value is 0.1, and the recommended maximum value is 100.0. Based on your knowledge of the objective function and initial guess you can increase or decrease the initial trust region. It can influence the iteration process, for example, the direction of the iteration process and the number of iterations. If you set <i>rs</i> to 0.0, the solver uses the default value, which is 100.0.

Output Parameters

<i>handle</i>	Type <code>_TRNSP_HANDLE_t</code> .
<i>res</i>	Indicates task completion status. • <i>res</i> = <code>TR_SUCCESS</code> - the routine completed the task normally. • <i>res</i> = <code>TR_INVALID_OPTION</code> - there was an error in the input parameters. • <i>res</i> = <code>TR_OUT_OF_MEMORY</code> - there was a memory error. <code>TR_SUCCESS</code>, <code>TR_INVALID_OPTION</code>, and <code>TR_OUT_OF_MEMORY</code> are defined in the <code>mkl_rci.h</code> include file.

See Also[?trnlsp_solve](#)**?trnlsp_check**

Checks the correctness of handle and arrays containing Jacobian matrix, objective function, and stopping criteria.

Syntax

```
MKL_INT strnlsp_check (_TRNSP_HANDLE_t* &handle, const MKL_INT* &n, const MKL_INT* &m,
const float* fjac, const float* fvec, const float* eps, MKL_INT* info);
```

```
MKL_INT dtrnlsp_check (_TRNSP_HANDLE_t* &handle, const MKL_INT* &n, const MKL_INT* &m,
const double* fjac, const double* fvec, const double* eps, MKL_INT* info);
```

Include Files

- mkl.h

Description

The `?trnlsp_check` routine checks the arrays passed into the solver as input parameters. If an array contains any INF or NaN values, the routine sets the flag in output array *info* (see the description of the values returned in the Output Parameters section for the *info* array).

Input Parameters

<i>handle</i>	Type <code>_TRNSPBC_HANDLE_t</code> .
<i>n</i>	Length of <i>x</i> .
<i>m</i>	Length of <i>F(x)</i> .
<i>fjac</i>	Array of size <i>m</i> by <i>n</i> . Contains the Jacobian matrix of the function.
<i>fvec</i>	Array of size <i>m</i> . Contains the function values at <i>x</i> , where $fvec[i] = (y_i - f_i(x))$.
<i>eps</i>	Array of size 6; contains stopping criteria. See the values in the Description section of the ?trnlsp_init .

Output Parameters

info Array of size 6.
Results of input parameter checking:

Parameter	Used for	Value	Description
<i>info</i> [0]	Flags for <i>handle</i>	0	The handle is valid.
		1	The handle is not allocated.
<i>info</i> [1]	Flags for <i>fjac</i>	0	The <i>fjac</i> array is valid.
		1	The <i>fjac</i> array is not allocated

Parameter	Used for	Value	Description
<i>info</i> [2]	Flags for <i>fvec</i>	2	The <i>fjac</i> array contains NaN.
		3	The <i>fjac</i> array contains Inf.
		0	The <i>fvec</i> array is valid.
		1	The <i>fvec</i> array is not allocated
		2	The <i>fvec</i> array contains NaN.
<i>info</i> [3]	Flags for <i>eps</i>	3	The <i>fvec</i> array contains Inf.
		0	The <i>eps</i> array is valid.
		1	The <i>eps</i> array is not allocated
		2	The <i>eps</i> array contains NaN.
		3	The <i>eps</i> array contains Inf.
<i>info</i> [3]	Flags for <i>eps</i>	4	The <i>eps</i> array contains a value less than or equal to zero.

res

Information about completion of the task.

res = TR_SUCCESS - the routine completed the task normally.

TR_SUCCESS is defined in the `mk1_rci.h` include file.

?trnlsp_solve

Solves a nonlinear least squares problem using the TR algorithm.

Syntax

```
MKL_INT strnlsp_solve (_TRNSP_HANDLE_t* &handle, float* fvec, float* fjac, MKL_INT*
&RCI_Request);
```

```
MKL_INT dtrnlsp_solve (_TRNSP_HANDLE_t* &handle, double* fvec, double* fjac, MKL_INT*
&RCI_Request);
```

Include Files

- `mk1.h`

Description

The ?trnlsp_solve routine uses the TR algorithm to solve nonlinear least squares problems.

The problem is stated as follows:

$$\min_{x \in R^n} \|F(x)\|_2^2 = \min_{x \in R^n} \|y - f(x)\|_2^2, y \in R^m, x \in R^n, f: R^n \rightarrow R^m, m \geq n,$$

where

- $F(x) : \mathbb{R}^n \rightarrow \mathbb{R}^m$
- $m \geq n$

From a current point $x_{current}$, the algorithm uses the trust-region approach:

$$\min_{x \in \mathbb{R}^n} \|F(x_{current}) + J(x_{current})(x_{new} - x_{current})\|_2^2 \quad \text{subject to} \quad \|x_{new} - x_{current}\| \leq \Delta_{current}$$

to get $x_{new} = x_{current} + s$ that satisfies

$$\min_{s \in \mathbb{R}^n} \|J^T(x)J(x)s + J^T F(x)\|_2^2$$

where

- $J(x)$ is the Jacobian matrix
- s is the trial step
- $\|s\|_2 \leq \Delta_{current}$

The *RCI_Request* parameter provides additional information:

<i>RCI_Request</i> Value	Description
2	Request to calculate the Jacobian matrix and put the result into <i>fjac</i>
1	Request to recalculate the function at vector <i>x</i> and put the result into <i>fvec</i>
0	One successful iteration step on the current trust-region radius (that does not mean that the value of <i>x</i> has changed)
-1	The algorithm has exceeded the maximum number of iterations
-2	$\Delta < eps[0]$
-3	$\ F(x)\ _2 < eps[1]$
-4	The Jacobian matrix is singular. $\ J(x)_{[m*(j-1)...m*j-1]}\ _2 < eps[2], j = 1, \dots, n$
-5	$\ s\ _2 < eps[3]$
-6	$\ F(x)\ _2 - \ F(x) - J(x)s\ _2 < eps[4]$

Note:

- $J(x)$ is the Jacobian matrix.
- Δ is the trust-region area.
- $F(x)$ is the value of the functional.
- s is the trial step.

Input Parameters

handle Type `_TRNSP_HANDLE_t`.

<i>fvec</i>	Array of size m . Contains the function values at x , where $fvec[i] = (y_i - f_i(x))$.
<i>fjac</i>	Array of size m by n . Contains the Jacobian matrix of the function.

Output Parameters

<i>fvec</i>	Array of size m . Updated function evaluated at x .
<i>RCI_Request</i>	Informs about the task stage. See the Description section for the parameter values and their meaning.
<i>res</i>	Indicates the task completion. $res = TR\_SUCCESS$ - the routine completed the task normally. $TR\_SUCCESS$ is defined in the <code>mkl_rci.h</code> include file.

?trnlsp_get

Retrieves the number of iterations, stop criterion, initial residual, and final residual.

Syntax

```

MKL_INT strnlsp_get(_TRNSP_HANDLE_t* &handle, MKL_INT* &iter, MKL_INT* &st_cr, float*
&r1, float* &r2);

MKL_INT dtrnlsp_get (_TRNSP_HANDLE_t* &handle, MKL_INT* &iter, MKL_INT* &st_cr, double*
&r1, double* &r2);

```

Include Files

- `mkl.h`

Description

The routine retrieves the current number of iterations, the stop criterion, the initial residual, and final residual.

The initial residual is the value of the functional $(||y - f(x)||)$ of the initial x values provided by the user.

The final residual is the value of the functional $(||y - f(x)||)$ of the final x resulting from the algorithm operation.

The *st_cr* parameter contains a number indicating the stop criterion:

<i>st_cr</i> Value	Description
1	The algorithm has exceeded the maximum number of iterations
2	$\Delta < eps[0]$
3	$ F(x) _2 < eps[1]$
4	The Jacobian matrix is singular. $J(x)_{[m*(j-1)...m*j-1]} _2 < eps[2], j = 1, \dots, n$
5	$ s _2 < eps[3]$

<i>st_cr</i> Value	Description
6	$ F(x) _2 - F(x) - J(x)s _2 < eps[4]$

Note:

- $J(x)$ is the Jacobian matrix.
- Δ is the trust-region area.
- $F(x)$ is the value of the functional.
- s is the trial step.

Input Parameters

handle Type `_TRNSP_HANDLE_t`.

Output Parameters

iter Contains the current number of iterations.

st_cr Contains the stop criterion.
See the Description section for the parameter values and their meanings.

r1 Contains the residual, $(||y - f(x)||)$ given the initial x .

r2 Contains the final residual, that is, the value of the functional $(||y - f(x)||)$ of the final x resulting from the algorithm operation.

res Indicates the task completion.
`res = TR_SUCCESS` - the routine completed the task normally.
`TR_SUCCESS` is defined in the `mkl_rci.h` include file.

?trnlsp_delete

Releases allocated data.

Syntax

```
MKL_INT strnlsp_delete(_TRNSP_HANDLE_t* &handle);
MKL_INT dtrnlsp_delete(_TRNSP_HANDLE_t* &handle);
```

Include Files

- `mkl.h`

Description

The `?trnlsp_delete` routine releases all memory allocated for the handle.

This routine flags memory as not used, but to actually release all memory you must call the support function [mkl_free_buffers](#).

Input Parameters

handle Type `_TRNSP_HANDLE_t`.

Output Parameters

`res` Indicates the task completion.

`res = TR_SUCCESS` means the routine completed the task normally.

`TR_SUCCESS` is defined in the `mkl_rci.h` include file.

Nonlinear Least Squares Problem with Linear (Bound) Constraints

The nonlinear least squares problem with linear bound constraints is very similar to the [nonlinear least squares problem without constraints](#) but it has the following constraints:

$$l_i \leq x_i \leq u_i, i = 1, \dots, n, \quad l, u \in R^n.$$

See usage examples in the `examples\solverc\source` folder of your Intel MKL directory. Specifically, see `ex_nlsqp_bc_c.c`.

RCI TR Routines for Problem with Bound Constraints

Routine Name	Operation
<code>?trnlsqbc_init</code>	Initializes the solver.
<code>?trnlsqbc_check</code>	Checks correctness of the input parameters.
<code>?trnlsqbc_solve</code>	Solves a nonlinear least squares problem using RCI and the Trust-Region algorithm.
<code>?trnlsqbc_get</code>	Retrieves the number of iterations, stop criterion, initial residual, and final residual.
<code>?trnlsqbc_delete</code>	Releases allocated data.

?trnlsqbc_init

Initializes the solver of nonlinear least squares problem with linear (boundary) constraints.

Syntax

```
MKL_INT strnlsqbc_init (_TRNSQBC_HANDLE_t* &handle, const MKL_INT* &n, const MKL_INT* &m, const float* x, const float* LW, const float* UP, const float* eps, const MKL_INT* &iter1, const MKL_INT* &iter2, const float* &rs);
```

```
MKL_INT dtrnlsqbc_init (_TRNSQBC_HANDLE_t* &handle, const MKL_INT* &n, const MKL_INT* &m, const double* x, const double* LW, const double* UP, const double* eps, const MKL_INT* &iter1, const MKL_INT* &iter2, const double* &rs);
```

Include Files

- `mkl.h`

Description

The `?trnlsqbc_init` routine initializes the solver.

After initialization all subsequent invocations of the `?trnlspsc_solve` routine should use the values of the handle returned by `?trnlspsc_init`.

The `eps` array contains a number indicating the stopping criteria:

<code>eps</code> Value	Description
0	$\Delta < eps[0]$
1	$ F(x) _2 < eps[1]$
2	The Jacobian matrix is singular. $ J(x)_{[m*(j-1)...m*j-1]} _2 < eps[2], j = 1, \dots, n$
3	$ s _2 < eps[3]$
4	$ F(x) _2 - F(x) - J(x)s _2 < eps[4]$
5	The trial step precision. If $eps[5] = 0$, then the trial step meets the required precision ($\leq 1.0*10^{-10}$).

Note:

- $J(x)$ is the Jacobian matrix.
- Δ is the trust-region area.
- $F(x)$ is the value of the functional.
- s is the trial step.

Input Parameters

<code>n</code>	Length of x .
<code>m</code>	Length of $F(x)$.
<code>x</code>	Array of size n . Initial guess.
<code>LW</code>	Array of size n . Contains low bounds for x ($lw_i < x_i$).
<code>UP</code>	Array of size n . Contains upper bounds for x ($up_i > x_i$).
<code>eps</code>	Array of size 6; contains stopping criteria. See the values in the Description section.
<code>iter1</code>	Specifies the maximum number of iterations.
<code>iter2</code>	Specifies the maximum number of iterations of trial step calculation.
<code>rs</code>	Definition of initial size of the trust region (boundary of the trial step). The recommended minimum value is 0.1, and the recommended maximum value is 100.0. Based on your knowledge of the objective function and initial guess you can increase or decrease the initial trust region. It can influence the iteration process, for example, the direction of the iteration process and the number of iterations. If you set <code>rs</code> to 0.0, the solver uses the default value, which is 100.0.

Output Parameters

<i>handle</i>	Type <code>_TRNSPBC_HANDLE_t</code> .
<i>res</i>	Informs about the task completion. <code>res = TR_SUCCESS</code> - the routine completed the task normally. <code>res = TR_INVALID_OPTION</code> - there was an error in the input parameters. <code>res = TR_OUT_OF_MEMORY</code> - there was a memory error. <code>TR_SUCCESS</code>, <code>TR_INVALID_OPTION</code>, and <code>TR_OUT_OF_MEMORY</code> are defined in the <code>mkl_rci.h</code> include file.

?trnlspsc_check

Checks the correctness of handle and arrays containing Jacobian matrix, objective function, lower and upper bounds, and stopping criteria.

Syntax

```
MKL_INT strnlspsc_check (_TRNSPBC_HANDLE_t* &handle, const MKL_INT* &n, const MKL_INT* &m, const float* fjac, const float* fvec, const float* LW, const float* UP, const float* eps, MKL_INT* info);
```

```
MKL_INT dtrnlspsc_check (_TRNSPBC_HANDLE_t* &handle, const MKL_INT* &n, const MKL_INT* &m, const double* fjac, const double* fvec, const double* LW, const double* UP, const double* eps, MKL_INT* info);
```

Include Files

- `mkl.h`

Description

The `?trnlspsc_check` routine checks the arrays passed into the solver as input parameters. If an array contains any `INF` or `NaN` values, the routine sets the flag in output array *info* (see the description of the values returned in the Output Parameters section for the *info* array).

Input Parameters

<i>handle</i>	Type <code>_TRNSPBC_HANDLE_t</code> .
<i>n</i>	Length of x .
<i>m</i>	Length of $F(x)$.
<i>fjac</i>	Array of size m by n . Contains the Jacobian matrix of the function.
<i>fvec</i>	Array of size m . Contains the function values at x , where $fvec[i] = (y_i - f_i(x))$.
<i>LW</i>	Array of size n. Contains low bounds for x ($lw_i < x_i$).
<i>UP</i>	Array of size n .

Contains upper bounds for x ($up_i > x_i$).

eps

Array of size 6; contains stopping criteria. See the values in the Description section of the `?trnlspbc_init`.

Output Parameters

info

Array of size 6.

Results of input parameter checking:

Parameter	Used for	Value	Description
<i>info</i> [0]	Flags for <i>handle</i>	0	The handle is valid.
		1	The handle is not allocated.
<i>info</i> [1]	Flags for <i>fjac</i>	0	The <i>fjac</i> array is valid.
		1	The <i>fjac</i> array is not allocated
		2	The <i>fjac</i> array contains NaN.
		3	The <i>fjac</i> array contains Inf.
<i>info</i> [2]	Flags for <i>fvec</i>	0	The <i>fvec</i> array is valid.
		1	The <i>fvec</i> array is not allocated
		2	The <i>fvec</i> array contains NaN.
		3	The <i>fvec</i> array contains Inf.
<i>info</i> [3]	Flags for <i>LW</i>	0	The <i>LW</i> array is valid.
		1	The <i>LW</i> array is not allocated
		2	The <i>LW</i> array contains NaN.
		3	The <i>LW</i> array contains Inf.
		4	The lower bound is greater than the upper bound.
<i>info</i> [4]	Flags for <i>up</i>	0	The <i>up</i> array is valid.
		1	The <i>up</i> array is not allocated
		2	The <i>up</i> array contains NaN.
		3	The <i>up</i> array contains Inf.
		4	The upper bound is less than the lower bound.
<i>info</i> [5]	Flags for <i>eps</i>	0	The <i>eps</i> array is valid.
		1	The <i>eps</i> array is not allocated

Parameter	Used for	Value	Description
		2	The <i>eps</i> array contains NaN.
		3	The <i>eps</i> array contains Inf.
		4	The <i>eps</i> array contains a value less than or equal to zero.

res

Information about completion of the task.

res = TR_SUCCESS - the routine completed the task normally.

TR_SUCCESS is defined in the `mkl_rci.h` include file.

?trnlspsc_solve

Solves a nonlinear least squares problem with linear (bound) constraints using the Trust-Region algorithm.

Syntax

```
MKL_INT strnlspsc_solve (_TRNSPBC_HANDLE_t* &handle, float* fvec, float* fjac, MKL_INT* &RCI_Request);
```

```
MKL_INT dtrnlspsc_solve (_TRNSPBC_HANDLE_t* &handle, double* fvec, double* fjac, MKL_INT* &RCI_Request);
```

Include Files

- `mkl.h`

Description

The `?trnlspsc_solve` routine, based on RCI, uses the Trust-Region algorithm to solve nonlinear least squares problems with linear (bound) constraints. The problem is stated as follows:

$$\min_{x \in \mathbb{R}^n} \|F(x)\|_2^2 = \min_{x \in \mathbb{R}^n} \|y - f(x)\|_2^2, y \in \mathbb{R}^m, x \in \mathbb{R}^n, f: \mathbb{R}^n \rightarrow \mathbb{R}^m, m \geq n$$

where

$$l_i \leq x_i \leq u_i$$

$$i = 1, \dots, n.$$

The *RCI_Request* parameter provides additional information:

<i>RCI_Request</i> Value	Description
2	Request to calculate the Jacobian matrix and put the result into <i>fjac</i>
1	Request to recalculate the function at vector <i>x</i> and put the result into <i>fvec</i>
0	One successful iteration step on the current trust-region radius (that does not mean that the value of <i>x</i> has changed)

<i>RCI_Request</i> Value	Description
-1	The algorithm has exceeded the maximum number of iterations
-2	$\Delta < eps[0]$
-3	$ F(x) _2 < eps[1]$
-4	The Jacobian matrix is singular. $ J(x)_{[m*(j-1)...m*j-1]} _2 < eps[2], j = 1, \dots, n$
-5	$ s _2 < eps[3]$
-6	$ F(x) _2 - F(x) - J(x)s _2 < eps[4]$

Note:

- $J(x)$ is the Jacobian matrix.
- Δ is the trust-region area.
- $F(x)$ is the value of the functional.
- s is the trial step.

Input Parameters

<i>handle</i>	Type <code>_TRANSPBC_HANDLE_t</code> .
<i>fvec</i>	Array of size m . Contains the function values at x , where $fvec[i] = (y_i - f_i(x))$.
<i>fjac</i>	Array of size m by n . Contains the Jacobian matrix of the function.

Output Parameters

<i>fvec</i>	Array of size m . Updated function evaluated at x .
<i>RCI_Request</i>	Informs about the task stage. See the Description section for the parameter values and their meaning.
<i>res</i>	Informs about the task completion. $res = \text{TR\_SUCCESS}$ means the routine completed the task normally. <code>TR_SUCCESS</code> is defined in the <code>mkl_rci.h</code> include file.

?trnlspsc_get

Retrieves the number of iterations, stop criterion, initial residual, and final residual.

Syntax

```

MKL_INT strnlspsc_get (_TRANSPBC_HANDLE_t* &handle, MKL_INT* &iter, MKL_INT* &st_cr,
float* &r1, float* &r2);

MKL_INT dtrnlspsc_get (_TRANSPBC_HANDLE_t* &handle, MKL_INT* &iter, MKL_INT* &st_cr,
double* &r1, double* &r2);

```

Include Files

- `mk1.h`

Description

The routine retrieves the current number of iterations, the stop criterion, the initial residual, and final residual.

The `st_cr` parameter contains a number indicating the stop criterion:

<code>st_cr</code> Value	Description
1	The algorithm has exceeded the maximum number of iterations
2	$\Delta < eps[0]$
3	$ F(x) _2 < eps[1]$
4	The Jacobian matrix is singular. $ J(x)_{[m*(j-1)...m*j-1]} _2 < eps[2], j = 1, \dots, n$
5	$ s _2 < eps[3]$
6	$ F(x) _2 - F(x) - J(x)s _2 < eps[4]$

Note:

- $J(x)$ is the Jacobian matrix.
- Δ is the trust-region area.
- $F(x)$ is the value of the functional.
- s is the trial step.

Input Parameters

`handle` Type `_TRNSPBC_HANDLE_t`.

Output Parameters

`iter` Contains the current number of iterations.

`st_cr` Contains the stop criterion.
See the Description section for the parameter values and their meanings.

`r1` Contains the residual, $(||y - f(x)||)$ given the initial x .

`r2` Contains the final residual, that is, the value of the function $(||y - f(x)||)$ of the final x resulting from the algorithm operation.

`res` Informs about the task completion.
`res = TR_SUCCESS` - the routine completed the task normally.
`TR_SUCCESS` is defined in the `mk1_rci.h` include file.

?trnlspsc_delete

Releases allocated data.

Syntax

```
MKL_INT strnlspbc_delete (_TRNSPBC_HANDLE_t* &handle);
MKL_INT dtrnlspbc_delete (_TRNSPBC_HANDLE_t* &handle);
```

Include Files

- `mkl.h`

Description

The `?trnlspbc_delete` routine releases all memory allocated for the handle.

NOTE

This routine flags memory as not used, but to actually release all memory you must call the support function `mkl_free_buffers`.

Input Parameters

`handle` Type `_TRNSPBC_HANDLE_t`.

Output Parameters

`res` Informs about the task completion.

`res = TR_SUCCESS` means the routine completed the task normally.

`TR_SUCCESS` is defined in the `mkl_rci.h` include file.

Jacobian Matrix Calculation Routines

This section describes routines that compute the Jacobian matrix using the central difference algorithm. Jacobian matrix calculation is required to solve a nonlinear least squares problem and systems of nonlinear equations (with or without linear bound constraints). Routines for calculation of the Jacobian matrix have the "Black-Box" interfaces, where you pass the objective function via parameters. Your objective function must have a fixed interface.

Jacobian Matrix Calculation Routines

Routine Name	Operation
<code>?jacobi_init</code>	Initializes the solver.
<code>?jacobi_solve</code>	Computes the Jacobian matrix of the function on the basis of RCI using the central difference algorithm.
<code>?jacobi_delete</code>	Removes data.
<code>?jacobi</code>	Computes the Jacobian matrix of the <code>fcn</code> function using the central difference algorithm.
<code>?jacobix</code>	Presents an alternative interface for the <code>?jacobi</code> function enabling you to pass additional data into the objective function.

?jacobi_init

Initializes the solver for Jacobian calculations.

Syntax

```
MKL_INT sjacobi_init (_JACOBI_MATRIX_HANDLE_t* &handle, const MKL_INT* &n, const
MKL_INT* &m, const float* x, const float* fjac, const float* &eps);
```

```
MKL_INT djacobi_init (_JACOBI_MATRIX_HANDLE_t* &handle, const MKL_INT* &n, const
MKL_INT* &m, const double* x, const double* fjac, const double* &eps);
```

Include Files

- mkl.h

Description

The routine initializes the solver.

Input Parameters

<i>n</i>	Length of <i>x</i> .
<i>m</i>	Length of <i>F</i> .
<i>x</i>	Array of size <i>n</i> . Vector, at which the function is evaluated.
<i>eps</i>	Precision of the Jacobian matrix calculation.
<i>fjac</i>	Array of size <i>m</i> by <i>n</i> . Contains the Jacobian matrix of the function.

Output Parameters

<i>handle</i>	Data object of the <code>_JACOBI_MATRIX_HANDLE_t</code> type.
<i>res</i>	Indicates task completion status. • <i>res</i> = <code>TR_SUCCESS</code> - the routine completed the task normally. • <i>res</i> = <code>TR_INVALID_OPTION</code> - there was an error in the input parameters. • <i>res</i> = <code>TR_OUT_OF_MEMORY</code> - there was a memory error. <code>TR_SUCCESS</code>, <code>TR_INVALID_OPTION</code>, and <code>TR_OUT_OF_MEMORY</code> are defined in the <code>mkl_rci.h</code> include file.

?jacobi_solve

Computes the Jacobian matrix of the function using RCI and the central difference algorithm.

Syntax

```
MKL_INT sjacobi_solve (_JACOBI_MATRIX_HANDLE_t* &handle, float* f1, float* f2, MKL_INT*
&RCI_Request);
```

```
MKL_INT djacobi_solve (_JACOBI_MATRIX_HANDLE_t* &handle, double* f1, double* f2,
MKL_INT* &RCI_Request);
```

Include Files

- mkl.h

Description

The `?jacobi_solve` routine computes the Jacobian matrix of the function using RCI and the central difference algorithm.

See usage examples in the `examples\solverc\source` folder of your Intel MKL directory. Specifically, see `sjacobi_rci_c.c` and `djacobi_rci_c.c`.

Input Parameters

<i>handle</i>	Type <code>_JACOBI_MATRIX_HANDLE_t</code> .
<i>RCI_Request</i>	Set to 0 before the first call to <code>?jacobi_solve</code> .

Output Parameters

<i>f1</i>	Contains the updated function values at $x + \text{eps}$.
<i>f2</i>	Array of size m . Contains the updated function values at $x - \text{eps}$.
<i>RCI_Request</i>	Provides information about the task completion. When equal to 0, the task has completed successfully. <i>RCI_Request</i> = 1 indicates that you should compute the function values at the current x point and put the results into <i>f1</i> . <i>RCI_Request</i> = 2 indicates that you should compute the function values at the current x point and put the results into <i>f2</i> .
<i>res</i>	Indicates the task completion status. <i>res</i> = <code>TR_SUCCESS</code> - the routine completed the task normally. <i>res</i> = <code>TR_INVALID_OPTION</code> - there was an error in the input parameters. <code>TR_SUCCESS</code> and <code>TR_INVALID_OPTION</code> are defined in the <code>mkl_rci.h</code> include file.

See Also

[?jacobi_init](#)

?jacobi_delete

Releases allocated data.

Syntax

```
MKL_INT sjacobi_delete (_JACOBI_MATRIX_HANDLE_t* &handle);
MKL_INT djacobi_delete (_JACOBI_MATRIX_HANDLE_t* &handle);
```

Include Files

- `mkl.h`

Description

The `?jacobi_delete` routine releases all memory allocated for the handle.

This routine flags memory as not used, but to actually release all memory you must call the support function [mkl_free_buffers](#).

Input Parameters

handle Type `_JACOBI_MATRIX_HANDLE_t`.

Output Parameters

res Informs about the task completion.

res = `TR_SUCCESS` means the routine completed the task normally.

`TR_SUCCESS` is defined in the `mkl_rci.h` include file.

?jacobi

Computes the Jacobian matrix of the objective function using the central difference algorithm.

Syntax

```
MKL_INT sjacobi (USRFCNS fcn, const MKL_INT* &n, const MKL_INT* &m, float* fjac, float*
x, float* &eps);

MKL_INT djacobi (USRFCND fcn, const MKL_INT* &n, const MKL_INT* &m, double* fjac,
double* x, double* &eps);
```

Include Files

- `mkl.h`

Description

The `?jacobi` routine computes the Jacobian matrix for function *fcn* using the central difference algorithm. This routine has a "Black-Box" interface, where you input the objective function via parameters. Your objective function must have a fixed interface.

See calling and usage examples in the `examples\solverc\source` folder of your Intel MKL directory. Specifically, see `ex_nlsqp_c.c` and `ex_nlsqp_bc_c.c`.

Input Parameters

fcn User-supplied subroutine to evaluate the function that defines the least squares problem. Call *fcn* (*m*, *n*, *x*, *f*) with the following parameters:

Parameter	Type	Description
Input Parameters		
<i>m</i>		Length of <i>f</i>
<i>n</i>		Length of <i>x</i>
<i>x</i>		Array of size <i>n</i> . Vector, at which the function is evaluated. The <i>fcn</i> function should not change this parameter.
Output Parameters		
<i>f</i>		Array of size <i>m</i> ; contains the function values at <i>x</i> .

	You need to declare <code>fcn</code> as <code>extern</code> in the calling program.
<code>n</code>	Length of X .
<code>m</code>	Length of F .
<code>x</code>	Array of size n . Vector at which the function is evaluated.
<code>eps</code>	Precision of the Jacobian matrix calculation.

Output Parameters

<code>fjac</code>	Array of size m by n . Contains the Jacobian matrix of the function.
<code>res</code>	Indicates task completion status. • <code>res = TR_SUCCESS</code> - the routine completed the task normally. • <code>res = TR_INVALID_OPTION</code> - there was an error in the input parameters. • <code>res = TR_OUT_OF_MEMORY</code> - there was a memory error. <code>TR_SUCCESS</code>, <code>TR_INVALID_OPTION</code>, and <code>TR_OUT_OF_MEMORY</code> are defined in the <code>mkl_rci.h</code> include file.

See Also

[?jacobix](#)

[?jacobix](#)

Alternative interface for [?jacobi](#) function for passing additional data into the objective function.

Syntax

```
MKL_INT sjacobix (USRFCNXS fcn, const MKL_INT* &n, const MKL_INT * &m, float* fjac,
float* x, float* &eps, void* user_data);

MKL_INT djacobix (USRFCNXD fcn, const MKL_INT* &n, const MKL_INT * &m, double* fjac,
double* x, double* &eps, void* user_data);
```

Include Files

- `mkl.h`

Description

The `?jacobix` routine presents an alternative interface for the `?jacobi` function that enables you to pass additional data into the objective function `fcn`.

See calling and usage examples in the `examples\solverc\source` folder of your Intel MKL directory. Specifically, see `ex_nlsqp_c_x.c` and `ex_nlsqp_bc_c_x.c`.

Input Parameters

<code>fcn</code>	User-supplied subroutine to evaluate the function that defines the least squares problem. Call <code>fcn (&m, &n, x, f, user_data)</code> with the following parameters:

Parameter	Description
Input Parameters	
m	Length of f
n	Length of x
x	Array of size n . Vector, at which the function is evaluated. The <code>fcn</code> function should not change this parameter.
<code>user_data</code>	Pointer to your additional data, if any. Otherwise, a dummy argument.
Output Parameters	
f	Array of size m ; contains the function values at x .

You need to declare `fcn` as `extern` in the calling program.

n	Length of X .
m	Length of F .
x	Array of size n . Vector at which the function is evaluated.
<code>eps</code>	Precision of the Jacobian matrix calculation.
<code>user_data</code>	Pointer to your additional data. If there is no additional data, this is a dummy argument.

Output Parameters

<code>fjac</code>	Array of size m by n). Contains the Jacobian matrix of the function.
<code>res</code>	Indicates task completion status. <code>res = TR_SUCCESS</code> - the routine completed the task normally. <code>res = TR_INVALID_OPTION</code> - there was an error in the input parameters. <code>res = TR_OUT_OF_MEMORY</code> - there was a memory error. <code>TR_SUCCESS</code>, <code>TR_INVALID_OPTION</code>, and <code>TR_OUT_OF_MEMORY</code> are defined in the <code>mkl_rci.h</code> include file.

Support Functions

Intel® Math Kernel Library (Intel® MKL) support functions are subdivided into the following groups according to their purpose:

[Version Information](#)

[Threading Control](#)

[Error Handling](#)

[Character Equality Testing](#)

[Timing](#)

[Memory Management](#)

[Single Dynamic Library Control](#)

[Intel® Many Integrated Core \(Intel® MIC\) Architecture Support](#)

[Conditional Numerical Reproducibility Control](#)

[Miscellaneous](#)

The following table lists Intel MKL support functions.

Intel MKL Support Functions

Function Name	Operation
Version Information	
<code>mkl_get_version</code>	Returns the Intel MKL version.
<code>mkl_get_version_string</code>	Returns the Intel MKL version in a character string.
Threading Control	
<code>mkl_set_num_threads</code>	Specifies the number of OpenMP* threads to use.
<code>mkl_domain_set_num_threads</code>	Specifies the number of OpenMP* threads for a particular function domain.
<code>mkl_set_num_threads_local</code>	Specifies the number of OpenMP* threads for all Intel MKL functions on the current execution thread.
<code>mkl_set_dynamic</code>	Enables Intel MKL to dynamically change the number of OpenMP* threads.
<code>mkl_get_max_threads</code>	Gets the number of OpenMP* threads targeted for parallelism.
<code>mkl_domain_get_max_threads</code>	Gets the number of OpenMP* threads targeted for parallelism for a particular function domain.
<code>mkl_get_dynamic</code>	Determines whether Intel MKL is enabled to dynamically change the number of OpenMP* threads.
Error Handling	
<code>xerbla</code>	Error handling function called by BLAS, LAPACK, Vector Math, and Vector Statistics functions.

Function Name	Operation
<code>pxerbla</code>	Handles error conditions for the ScaLAPACK routines.
<code>mkl_set_exit_handler</code>	Sets the custom handler of fatal errors.
Character Equality Testing	
<code>lsame</code>	Tests two characters for equality regardless of the case.
<code>lsamen</code>	Tests two character strings for equality regardless of the case.
Timing	
<code>second/dsecnd</code>	Returns elapsed time in seconds. Use to estimate real time between two calls to this function.
<code>mkl_get_cpu_clocks</code>	Returns elapsed CPU clocks.
<code>mkl_get_cpu_frequency</code>	Returns CPU frequency value in GHz.
<code>mkl_get_max_cpu_frequency</code>	Returns the maximum CPU frequency value in GHz.
<code>mkl_get_clocks_frequency</code>	Returns the frequency value in GHz based on constant-rate Time Stamp Counter.
Memory Management	
<code>mkl_free_buffers</code>	Frees unused memory allocated by the Intel MKL Memory Allocator.
<code>mkl_thread_free_buffers</code>	Frees unused memory allocated by the Intel MKL Memory Allocator in the current thread.
<code>mkl_mem_stat</code>	Reports the status of the Intel MKL Memory Allocator.
<code>mkl_peak_mem_usage</code>	Reports the peak memory allocated by the Intel MKL Memory Allocator.
<code>mkl_disable_fast_mm</code>	Turns off the Intel MKL Memory Allocator for Intel MKL functions to directly use the system <code>malloc/free</code> functions.
<code>mkl_malloc</code>	Allocates an aligned memory buffer.
<code>mkl_calloc</code>	Allocates and initializes an aligned memory buffer.
<code>mkl_realloc</code>	Changes the size of memory buffer allocated by <code>mkl_malloc/mkl_calloc</code> .
<code>mkl_free</code>	Frees the aligned memory buffer allocated by <code>mkl_malloc/mkl_calloc</code> .
<code>mkl_set_memory_limit</code>	On Linux, sets the limit of memory that Intel MKL can allocate for a specified type of memory.
Single Dynamic Library (SDL) Control	
<code>mkl_set_interface_layer</code>	Sets the interface layer for Intel MKL at run time.
<code>mkl_set_threading_layer</code>	Sets the threading layer for Intel MKL at run time.
<code>mkl_set_xerbla</code>	Replaces the error handling routine. Use with SDL on Windows* OS.

Function Name	Operation
<code>mkl_set_progress</code>	Replaces the progress information routine. Use with SDL on Windows* OS.
<code>mkl_set_pardiso_pivot</code>	Replaces the routine handling Intel MKL PARDISO pivots with a user-defined routine. Use with the Single Dynamic Library (SDL).
Intel MIC Architecture Support	
<code>mkl_mic_enable</code>	Enables Automatic Offload mode.
<code>mkl_mic_disable</code>	Disables Automatic Offload mode.
<code>mkl_mic_get_device_count</code>	Returns the number of Intel® Xeon Phi™ coprocessors on the system when called on the host CPU.
<code>mkl_mic_set_workdivision</code>	For computations in the Automatic Offload mode, sets the fraction of the work for the specified coprocessor or host CPU to do.
<code>mkl_mic_get_workdivision</code>	For computations in the Automatic Offload mode, retrieves the fraction of the work for the specified coprocessor or host CPU to do.
<code>mkl_mic_set_max_memory</code>	Sets the maximum amount of coprocessor memory reserved for Automatic Offload computations.
<code>mkl_mic_free_memory</code>	Frees the coprocessor memory reserved for Automatic Offload computations.
<code>mkl_mic_register_memory</code>	Enables/disables the <code>mkl_malloc</code> function running in Automatic Offload mode to register allocated memory.
<code>mkl_mic_set_device_num_threads</code>	Sets the maximum number of OpenMP* threads to use on an Intel Xeon Phi coprocessor for the Automatic Offload computations.
<code>mkl_mic_set_resource_limit</code>	For computations in the Automatic Offload mode, sets the maximum fraction of available Intel Xeon Phi coprocessor computational resources (cores) that the calling process can use.
<code>mkl_mic_get_resource_limit</code>	For computations in the Automatic Offload mode, retrieves the maximum fraction of available Intel Xeon Phi coprocessor computational resources (cores) that the calling process can use.
<code>mkl_mic_set_offload_report</code>	Turns on/off reporting of Automatic Offload profiling.
<code>mkl_mic_set_flags</code>	Sets flags to control the behavior of computations in the Automatic Offload mode.
<code>mkl_mic_get_flags</code>	Retrieves flags that control the behavior of computations in the Automatic Offload mode.
<code>mkl_mic_get_status</code>	For the Automatic Offload mode, returns the status of the latest call to an Intel MKL function.
<code>mkl_mic_clear_status</code>	For the Automatic Offload mode, clears the status of the latest call to an Intel MKL function.
<code>mkl_mic_get_meminfo</code>	Retrieves the amount of total and free memory for the specified coprocessor or host CPU.
<code>mkl_mic_get_cpuinfo</code>	Retrieves the number of cores, hardware threads, and frequency for the specified coprocessor or host CPU.

Function Name	Operation
Conditional Numerical Reproducibility (CNR) Control	
<code>mkl_cbwr_set</code>	Configures the CNR mode of Intel MKL.
<code>mkl_cbwr_get</code>	Returns the current CNR settings.
<code>mkl_cbwr_get_auto_branch</code>	Automatically detects the CNR code branch for your platform.
Miscellaneous	
<code>mkl_progress</code>	Tracks computational progress of selective Intel MKL routines.
<code>mkl_enable_instructions</code>	Enables Intel MKL to dispatch a new Intel® architecture on hardware (or simulation) supporting the appropriate instruction set.
<code>mkl_set_env_mode</code>	Sets up the mode that ignores environment settings specific to Intel MKL.
<code>mkl_verbose</code>	Enables or disables Intel MKL Verbose mode.
<code>mkl_set_mpi</code>	Sets the implementation of the message-passing interface to be used by Intel MKL.
<code>mkl_finalize</code>	Terminates Intel MKL execution environment and frees resources allocated by the library.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Version Information

Intel® MKL provides two methods for extracting information about the library version number:

- extracting a version string using the `mkl_get_version_string` function
- using the `mkl_get_version` function to obtain an `MKLVersion` structure that contains the version information

A makefile is also provided to automatically build the examples and output summary files containing the version information for the current library.

`mkl_get_version`

Returns the Intel MKL version.

Syntax

```
void mkl_get_version( MKLVersion* pVersion );
```

Include Files

- `mkL.h`

Output Parameters

`pVersion` Pointer to the `MKLVersion` structure.

Description

The `mkL_get_version` function collects information about the active C version of the Intel MKL software and returns this information in a structure of `MKLVersion` type by the `pVersion` address. The `MKLVersion` structure type is defined in the `mkL_types.h` file. The following fields of the `MKLVersion` structure are available:

<code>MajorVersion</code>	is the major number of the current library version.
<code>MinorVersion</code>	is the minor number of the current library version.
<code>UpdateVersion</code>	is the update number of the current library version.
<code>ProductStatus</code>	is the status of the current library version. Possible variants are "Beta" or "Product".
<code>Build</code>	is the string that contains the build date and the internal build number.
<code>Platform</code>	is the string that contains the current architecture. Possible variants are "IA-32 architecture" or "Intel(R) 64 architecture".
<code>Processor</code>	is the processor optimization. Normally it is targeted for the processor installed on your system and based on the detection of the Intel MKL library that is optimal for the installed processor. In the Conditional Numerical Reproducibility (CNR) mode, the processor optimization matches the selected CNR branch.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

mkL_get_version Usage

```
#include <stdio.h>
#include <stdlib.h>
#include "mkL_service.h"

int main(void)
{
    MKLVersion Version;
```

```

mkl_get_version(&Version);

printf("Major version:           %d\n",Version.MajorVersion);
printf("Minor version:          %d\n",Version.MinorVersion);
printf("Update version:         %d\n",Version.UpdateVersion);
printf("Product status:         %s\n",Version.ProductStatus);
printf("Build:                  %s\n",Version.Build);
printf("Platform:               %s\n",Version.Platform);
printf("Processor optimization:  %s\n",Version.Processor);
printf("=====\\n");
printf("\\n");

return 0;
}

```

Output:

Major Version	11
Minor Version	0
Update Version	2
Product status	Product
Build	20121113
Platform	Intel(R) 64 architecture
Processor optimization	Intel(R) Core(TM) i7 Processor

mkl_get_version_string

Returns the Intel MKL version in a character string.

Syntax

```
void mkl_get_version_string (char* buf, int len);
```

Include Files

- mkl.h

Output Parameters

Name	Type	Description
<i>buf</i>	char*	Source string
<i>len</i>	int	Length of the source string

Description

The function returns a string that contains the Intel MKL version.

For usage details, see the code example below:

Example

```
#include <stdio.h>
#include "mkl_service.h"

int main(void)
{
    int len=198;
    char buf[198];
    mkl_get_version_string(buf, len);
    printf("%s\n",buf);
    printf("\n");
    return 0;
}
```

Threading Control

Intel® MKL provides functions for OpenMP* threading control, discussed in this section.

Important

If Intel MKL operates within the Intel® Threading Building Blocks (Intel® TBB) execution environment, the environment variables for OpenMP* threading control, such as `OMP_NUM_THREADS`, and Intel MKL functions discussed in this section have no effect. If the Intel TBB threading technology is used, control the number of threads through the Intel TBB application programming interface. Read the documentation for the `tbb::task_scheduler_init` class at <https://www.threadingbuildingblocks.org/documentation> to find out how to specify the number of Intel TBB threads.

If Intel® MKL operates within an OpenMP* execution environment, you can control the number of threads for Intel MKL using OpenMP* run-time library routines and environment variables (see the OpenMP* specification for details). Additionally Intel MKL provides *optional* threading control functions and environment variables that enable you to specify the number of threads for Intel MKL and to control dynamic adjustment of the number of threads *independently* of the OpenMP* settings. The settings made with the Intel MKL threading control functions and environment variables do not affect OpenMP* settings but take precedence over them.

If none of the threading control functions is used, Intel MKL environment variables may control Intel MKL threading. For details of those environment variables, see the *Intel MKL User's Guide*.

You can specify the number of threads for Intel MKL function domains with the [mkl_set_num_threads](#) or [mkl_domain_set_num_threads](#) function. While [mkl_set_num_threads](#) specifies the number of threads for the entire Intel MKL, [mkl_domain_set_num_threads](#) does it for a specific function domain. The following table lists the function domains that support independent threading control. The table also provides named constants to pass to threading control functions as a parameter that specifies the function domain.

Intel MKL Function Domains

Function Domain	Named Constant
Basic Linear Algebra Subroutines (BLAS)	<code>MKL_DOMAIN_BLAS</code>
Fast Fourier Transform (FFT) functions, except Cluster FFT functions	<code>MKL_DOMAIN_FFT</code>
Vector Math (VM) functions	<code>MKL_DOMAIN_VML</code>
Parallel Direct Solver (PARDISO) functions	<code>MKL_DOMAIN_PARDISO</code>
All Intel MKL functions except the functions from the domains where the number of threads is set explicitly	<code>MKL_DOMAIN_ALL</code>

WARNING

Do not increase the number of OpenMP threads used for Intel MKL PARDISO between the first call to `pardiso` and the factorization or solution phase. Because the minimum amount of memory required for out-of-core execution depends on the number of OpenMP threads, increasing it after the initial call can cause incorrect results.

Both `mkl_set_num_threads` and `mkl_domain_set_num_threads` functions set the number of threads for all subsequent calls to Intel MKL from all applications threads. Use the `mkl_set_num_threads_local` function to specify different numbers of threads for Intel MKL on different execution threads of your application. The thread-local settings take precedence over the global settings. However, the thread-local settings may have undesirable side effects (see the description of the `mkl_set_num_threads_local` function for details).

By default, Intel MKL can adjust the specified number of threads dynamically. For example, Intel MKL may use fewer threads if the size of the computation is not big enough or not create parallel regions when running within an OpenMP* parallel region. Although Intel MKL may actually use a different number of threads from the number specified, the library does not create parallel regions with more threads than specified. If dynamic adjustment of the number of threads is disabled, Intel MKL attempts to use the specified number of threads in internal parallel regions (for more information, see the *Intel MKL User's Guide*). Use the `mkl_set_dynamic` function to control dynamic adjustment of the number of threads.

`mkl_set_num_threads`

Specifies the number of OpenMP threads to use.*

Syntax

```
void mkl_set_num_threads( int nt );
```

Include Files

- `mkl.h`

Input Parameters

Name	Type	Description
<code>nt</code>	<code>int</code>	<code>nt > 0</code> - The number of threads suggested by the user. <code>nt ≤ 0</code> - Invalid value, which is ignored.

Description

This function enables you to specify how many OpenMP threads Intel MKL should use for internal parallel regions. If this number is not set (default), Intel MKL functions use the default number of threads for the OpenMP run-time library. The specified number of threads applies:

- To all Intel MKL functions except the functions from the domains where the number of threads is set with `mkl_domain_set_num_threads`
- To all execution threads except the threads where the number of threads is set with `mkl_set_num_threads_local`

The number specified is a hint, and Intel MKL may actually use a smaller number.

NOTE

This function takes precedence over the `MKL_NUM_THREADS` environment variable.

Example

```
#include "mkl_service.h"
...
mkl_set_num_threads(4);
my_compute_using_mkl();    // Intel MKL uses up to 4 OpenMP threads
```

mkl_domain_set_num_threads

Specifies the number of OpenMP threads for a particular function domain.*

Syntax

```
int mkl_domain_set_num_threads (int nt, int domain);
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>nt</i>	int	<i>nt</i> > 0 - The number of threads suggested by the user. <i>nt</i> = 0 - The default number of threads for the OpenMP run-time library. <i>nt</i> < 0 - Invalid value, which is ignored.
<i>domain</i>	int	The named constant that defines the targeted domain.

Description

This function specifies how many OpenMP threads a particular function domain of Intel MKL should use. If this number is not set (default) or if it is set to zero in a call to this function, Intel MKL uses the default number of threads for the OpenMP run-time library. The number of threads specified applies to the specified function domain on all execution threads except the threads where the number of threads is set with [mkl_set_num_threads_local](#). For a list of supported values of the *domain* argument, see [Table "Intel MKL Function Domains"](#).

The number of threads specified is only a hint, and Intel MKL may actually use a smaller number.

NOTE

This function takes precedence over the `MKL_DOMAIN_NUM_THREADS` environment variable.

Return Values

Name	Type	Description
<i>ierr</i>	int	1 - Indicates no error, execution is successful. 0 - Indicates a failure, possibly because of invalid input parameters.

Example

```
#include "mkl_service.h"
...
mkl_domain_set_num_threads(4, MKL_DOMAIN_BLAS);
my_compute_using_mkl_blas();    // Intel MKL BLAS functions use up to 4 threads
my_compute_using_mkl_dft();     // Intel MKL FFT functions use the default number of threads
```

mkl_set_num_threads_local

Specifies the number of OpenMP threads for all Intel MKL functions on the current execution thread.*

Syntax

```
int mkl_set_num_threads_local( int nt );
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>nt</i>	int	<i>nt</i> > 0 - The number of threads for Intel MKL functions to use on the current execution thread. <i>nt</i> = 0 - A request to reset the thread-local number of threads and use the global number.

Description

This function sets the number of OpenMP threads that Intel MKL functions should request for parallel computation. The number of threads is thread-local, which means that it only affects the current execution thread of the application. If the thread-local number is not set or if this number is set to zero in a call to this function, Intel MKL functions use the global number of threads. You can set the global number of threads using the [mkl_set_num_threads](#) or [mkl_domain_set_num_threads](#) function.

The thread-local number of threads takes precedence over the global number: if the thread-local number is non-zero, changes to the global number of threads have no effect on the current thread.

CAUTION

If your application is threaded with OpenMP* and parallelization of Intel MKL is based on nested OpenMP parallelism, different OpenMP parallel regions reuse OpenMP threads. Therefore a thread-local setting in one OpenMP parallel region may continue to affect not only the master thread after the parallel region ends, but also subsequent parallel regions. To avoid performance implications of this side effect, reset the thread-local number of threads before leaving the OpenMP parallel region (see [Examples](#) for how to do it).

Return Values

Name	Type	Description
<i>save_nt</i>	int	The value of the thread-local number of threads that was used before this function call. Zero means that the global number of threads was used.

Examples

This example shows how to avoid the side effect of a thread-local number of threads by reverting to the global setting:

```
#include "omp.h"
#include "mkl_service.h"
...
mkl_set_num_threads(16);
my_compute_using_mkl();           // Intel MKL functions use up to 16 threads
#pragma omp parallel num_threads(2)
{
    if (0 == omp_get_thread_num())
        mkl_set_num_threads_local(4);
    else
        mkl_set_num_threads_local(12);

    my_compute_using_mkl();         // Intel MKL functions use up to 4 threads on thread 0
//    and up to 12 threads on thread 1
}
my_compute_using_mkl();           // Intel MKL functions use up to 4 threads (!)
mkl_set_num_threads_local( 0 );   // make master thread use global setting
my_compute_using_mkl();           // Intel MKL functions use up to 16 threads
```

This example shows how to avoid the side effect of a thread-local number of threads by saving and restoring the existing setting:

```
#include "mkl_service.h"
void my_compute( int nt )
{
    int save = mkl_set_num_threads_local( nt );    // save the Intel MKL number of threads
    my_compute_using_mkl();                       // Intel MKL functions use up to nt threads on this thread
    mkl_set_num_threads_local( save );             // restore the Intel MKL number of threads
}
```

mkl_set_dynamic

Enables Intel MKL to dynamically change the number of OpenMP threads.*

Syntax

```
void mkl_set_dynamic (int flag);
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>flag</i>	int	<i>flag</i> = 0 - Requests disabling dynamic adjustment of the number of threads. <i>flag</i> ≠ 0 - Requests enabling dynamic adjustment of the number of threads.

Description

This function indicates whether Intel MKL can dynamically change the number of OpenMP threads or should avoid doing this. The setting applies to all Intel MKL functions on all execution threads. This function takes precedence over the `MKL_DYNAMIC` environment variable.

Dynamic adjustment of the number of threads is enabled by default. Specifically, Intel MKL may use fewer threads in parallel regions than the number returned by the [mkl_get_max_threads](#) function. Disabling dynamic adjustment of the number of threads does not ensure that Intel MKL actually uses the specified number of threads, although the library attempts to use that number.

TIP

If you call Intel MKL from within an OpenMP parallel region and want to create internal parallel regions, either disable dynamic adjustment of the number of threads or set the thread-local number of threads (see [mkl_set_num_threads_local](#) for how to do it).

Example

```
#include "mkl_service.h"
...
mkl_set_num_threads( 8 );
#pragma omp parallel
{
    my_compute_with_mkl();    // Intel MKL uses 1 thread, being called from OpenMP parallel region
    mkl_set_dynamic( 0 );    // disable adjustment of the number of threads
    my_compute_with_mkl();    // Intel MKL uses 8 threads
}
```

mkl_get_max_threads

Gets the number of OpenMP threads targeted for parallelism.*

Syntax

```
int mkl_get_max_threads (void);
```

Include Files

- mkl.h

Description

This function returns the number of OpenMP threads for Intel MKL to use in internal parallel regions. This number depends on whether dynamic adjustment of the number of threads by Intel MKL is disabled (by an environment setting or in a function call):

- If the dynamic adjustment is disabled, the function inspects the environment settings and return values of the function calls below in the order they are listed until it finds a non-zero value:
 - A call to [mkl_set_num_threads_local](#)
 - The last of the calls to [mkl_set_num_threads](#) or [mkl_domain_set_num_threads](#)(..., MKL_DOMAIN_ALL)
 - The MKL_DOMAIN_NUM_THREADS environment variable with the MKL_DOMAIN_ALL tag
 - The MKL_NUM_THREADS environment variable
 - A call to [omp_set_num_threads](#)
 - The OMP_NUM_THREADS environment variable
- If the dynamic adjustment is enabled, the function returns the number of physical cores on your system.

The number of threads returned by this function is a hint, and Intel MKL may actually use a different number.

Return Values

Name	Type	Description
<i>nt</i>	int	The maximum number of threads for Intel MKL functions to use in internal parallel regions.

Example

```
#include "mkl_service.h"
...
if (1 == mkl_get_max_threads()) puts("Intel MKL does not employ threading");
```

See Also

[mkl_set_dynamic](#)

[mkl_get_dynamic](#)

mkl_domain_get_max_threads

Gets the number of OpenMP threads targeted for parallelism for a particular function domain.*

Syntax

```
int mkl_domain_get_max_threads (int domain);
```

Include Files

- `mkl.h`

Input Parameters

Name	Type	Description
<i>domain</i>	int	The named constant that defines the targeted domain.

Description

Computational functions of the Intel MKL function domain defined by the *domain* parameter use the value returned by this function as a limit of the number of OpenMP threads they should request for parallel computations. The `mkl_domain_get_max_threads` function returns the thread-local number of threads or, if that value is zero or not set, the global number of threads. To determine this number, the function inspects the environment settings and return values of the function calls below in the order they are listed until it finds a non-zero value:

- A call to [mkl_set_num_threads_local](#)
- The last of the calls to [mkl_set_num_threads](#) or [mkl_domain_set_num_threads](#)(..., MKL_DOMAIN_ALL)
- A call to `mkl_domain_set_num_threads`(..., *domain*)
- The `MKL_DOMAIN_NUM_THREADS` environment variable with the `MKL_DOMAIN_ALL` tag
- The `MKL_DOMAIN_NUM_THREADS` environment variable (with the specific domain tag)
- The `MKL_NUM_THREADS` environment variable
- A call to `omp_set_num_threads`
- The `OMP_NUM_THREADS` environment variable

Actual number of threads used by the Intel MKL computational functions may vary depending on the problem size and on whether dynamic adjustment of the number of threads is enabled (see the description of [mkl_set_dynamic](#)). For a list of supported values of the *domain* argument, see [Table "Intel MKL Function Domains"](#).

Return Values

Name	Type	Description
<i>nt</i>	int	The maximum number of threads for Intel MKL functions from a given domain to use in internal parallel regions. If an invalid value of <i>domain</i> is supplied, the function returns the number of threads for MKL_DOMAIN_ALL

Example

```
#include "mkl_service.h"
...
if (1 < mkl_domain_get_max_threads(MKL_DOMAIN_BLAS))
puts("Intel MKL BLAS functions employ threading");
```

mkl_get_dynamic

Determines whether Intel MKL is enabled to dynamically change the number of OpenMP threads.*

Syntax

```
int mkl_get_dynamic(void);
```

Include Files

- mkl.h

Description

This function returns the status of dynamic adjustment of the number of OpenMP* threads. To determine this status, the function inspects the return value of the following function call and if it is undefined, inspects the environment setting below:

- A call to [mkl_set_dynamic](#)
- The MKL_DYNAMIC environment variable

NOTE

Dynamic adjustment of the number of threads is enabled by default.

The dynamic adjustment works as follows. Suppose that the [mkl_get_max_threads](#) function returns the number of threads equal to *N*. If dynamic adjustment is enabled, Intel MKL may request up to *N* threads, depending on the size of the problem. If dynamic adjustment is disabled, Intel MKL requests exactly *N* threads for internal parallel regions (provided it uses a threaded algorithm with at least *N* computations that can be done in parallel). However, the OpenMP* run-time library may be configured to supply fewer threads than Intel MKL requests, depending on the OpenMP* setting of dynamic adjustment.

Return Values

Name	Type	Description
<i>ret</i>	int	0 - Dynamic adjustment of the number of threads is disabled. 1 - Dynamic adjustment of the number of threads is enabled.

Example

```
#include "mkl_service.h"
...
int nt = mkl_get_max_threads();
if (1 == mkl_get_dynamic())
printf("Intel MKL may use less than %i threads for a large problem", nt);
else
printf("Intel MKL should use %i threads for a large problem", nt);
```

Error Handling

Error Handling for Linear Algebra Routines

xerbla

Error handling function called by BLAS, LAPACK, Vector Math, and Vector Statistics functions.

Syntax

```
void xerbla( const char * sname, const int* info, const int len );
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>sname</i>	const char*	The name of the routine that called xerbla
<i>info</i>	const int*	The position of the invalid parameter in the parameter list of the calling function or an error code
<i>len</i>	const int	Length of the source string

Description

The xerbla function is an error handler for Intel MKL BLAS, LAPACK, Vector Math, and Vector Statistics functions. These functions call xerbla if an issue is encountered on entry or during the function execution.

xerbla operates as follows:

1. Prints a message that depends on the value of the *info* parameter as explained in the [Error Messages Printed by xerbla](#) table.

NOTE

A specific message can differ from the listed messages in numeric values and/or function names.

2. Returns to the calling application.

Comments in the Netlib LAPACK reference code (http://www.netlib.org/lapack/explore-html/d1/dc0/_b_l_a_s_2_s_r_c_2xerbla_8f.html) suggest this behavior although the LAPACK User's Guide recommends that the execution should stop when an error occurs.

Error Messages Printed by xerbla

Value of <i>info</i>	Error Message
1001	Intel MKL ERROR: Incompatible optional parameters on entry to DGEMM.
1212	Intel MKL INTERNAL ERROR: Issue accessing coprocessor in function CGEEV.
1000 or 1089	Intel MKL INTERNAL ERROR: Insufficient workspace available in function CGELSD.
< 0	Intel MKL INTERNAL ERROR: Condition 1 detected in function DLASD8.
Other	Intel MKL ERROR: Parameter 6 was incorrect on entry to DGEMM.

Note that `xerbla` is an internal function. You can change or disable printing of an error message by providing your own `xerbla` function. The following examples illustrate usage of `xerbla`.

Example

```
void xerbla(char* sname, int* info, int len){
// sname - name of the function that called xerbla
// info - position of the invalid parameter in the parameter list
// len - length of the name in bytes
printf("\nXERBLA is called :%s: %d\n",sname,*info);
}
```

See Also

[mkl_set_xerbla](#)

pxerbla

Error handling routine called by ScaLAPACK routines.

Syntax

```
void pxerbla(MKL_INT* ictxt, char* sname, MKL_INT* info);
```

Include Files

- `mkl_scalapack.h`

Input Parameters

<i>ictxt</i>	(global) MKL_INT The BLACS context handle, indicating the global context of the operation. The context itself is global.
<i>sname</i>	(global) char The name of the routine which called <code>pxerbla</code> .
<i>info</i>	(global) MKL_INT. The position of the invalid parameter in the parameter list of the calling routine.

Description

This routine is an error handler for the *ScaLAPACK* routines. It is called if an input parameter has an invalid value. A message is printed and program execution continues. For *ScaLAPACK* driver and computational routines, a `RETURN` statement is issued following the call to `p_xerbla`.

Control returns to the higher-level calling routine, and you can determine how the program should proceed. However, in the specialized low-level *ScaLAPACK* routines (auxiliary routines that are Level 2 equivalents of computational routines), the call to `p_xerbla()` is immediately followed by a call to `BLACS_ABORT()` to terminate program execution since recovery from an error at this level in the computation is not possible.

It is always good practice to check for a non-zero value of *info* on return from a *ScaLAPACK* routine. Installers may consider modifying this routine in order to call system-specific exception-handling facilities.

Handling Fatal Errors

A fatal error is a circumstance under which Intel MKL cannot continue the computation. For example, a fatal error occurs when Intel MKL cannot load a dynamic library or confronts an unsupported CPU type. In case of a fatal error, the default Intel MKL behavior is to print an explanatory message to the console and call an internal function that terminates the application with a call to the system `exit()` function. Intel MKL enables you to override this behavior by setting a custom handler of fatal errors. The custom error handler can be configured to throw a C++ exception, set a global variable indicating the failure, or otherwise handle cannot-continue situations. It is not necessary for the custom error handler to call the system `exit()` function. Once execution of the error handler completes, a call to Intel MKL returns to the calling program without performing any computations and leaves no memory allocated by Intel MKL and no thread synchronization pending on return.

To specify a custom fatal error handler, call the `mkl_set_exit_handler` function.

`mkl_set_exit_handler`

Sets the custom handler of fatal errors.

Syntax

```
int mkl_set_exit_handler (MKLExitHandler myexit);
```

Include Files

- `mkl.h`

Input Parameters

Name	Prototype	Description
<code>myexit</code>	<code>void (*myexit)(int why);</code>	The error handler to set.

Description

This function sets the custom handler of fatal errors. If the input parameter is `NULL`, the system `exit()` function is set.

The following example shows how to use a custom handler of fatal errors in your C++ application:

```
#include "mkl.h"
void my_exit(int why){
    throw my_exception();
}
int ComputationFunction()
{
    mkl_set_exit_handler( my_exit );
    try {
```

```
    compute_using_mkl();  
}  
catch (const my_exception& e) {  
    handle_exception();  
}  
}
```

Character Equality Testing

lsame

Tests two characters for equality regardless of the case.

Syntax

```
int lsame( const char* ca, const char* cb, int lca, int lcb );
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>ca, cb</i>	const char*	Pointers to the single characters to be compared
<i>lca, lcb</i>	int	Lengths of the input character strings, equal to one.

Description

This logical function checks whether two characters are equal regardless of the case.

Return Values

Name	Type	Description
<i>val</i>	int	Result of the comparison: • a non-zero value if <i>ca</i> is the same letter as <i>cb</i>, maybe except for the case. • zero if <i>ca</i> and <i>cb</i> are different letters for whatever cases.

lsamen

Tests two character strings for equality regardless of the case.

Syntax

```
MKL_INT lsamen( const MKL_INT* n, const char* ca, const char* cb );
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>n</i>	<code>const MKL_INT*</code>	Pointer to the number of characters in <i>ca</i> and <i>cb</i> to be compared.
<i>ca, cb</i>	<code>const char*</code>	Character strings of length at least <i>n</i> to be compared. Only the first <i>n</i> characters of each string will be accessed.

Description

This logical function tests whether the first *n* letters of one string are the same as the first *n* letters of the other string, regardless of the case.

Return Values

Name	Type	Description
<i>val</i>	<code>MKL_INT</code>	Result of the comparison: • a non-zero value if the first <i>n</i> letters in <i>ca</i> and <i>cb</i> character strings are equal, maybe except for the case, or if the length of character string <i>ca</i> or <i>cb</i> is less than <i>n</i>. • zero if the first <i>n</i> letters in <i>ca</i> and <i>cb</i> character strings are different for whatever cases.

Timing

second/dsecnd

Returns elapsed time in seconds. Use to estimate real time between two calls to this function.

Syntax

```
float second( void );
double dsecnd( void );
```

Include Files

- `mk1.h`

Description

The `second/dsecnd` function returns time in seconds to be used to estimate real time between two calls to the function. The difference between these functions is in the precision of the floating-point type of the result: while `second` returns the single-precision type, `dsecnd` returns the double-precision type.

Use these functions to measure durations. To do this, call each of these functions twice. For example, to measure performance of a routine, call the appropriate function directly before a call to the routine to be measured, and then after the call of the routine. The difference between the returned values shows real time spent in the routine.

Initializations may take some time when the `second/dsecnd` function runs for the first time. To eliminate the effect of this extra time on your measurements, make the first call to `second/dsecnd` in advance.

Do not use `second` to measure short time intervals because the single-precision format is not capable of holding sufficient timer precision.

Return Values

Name	Type	Description
<code>val</code>	<code>float</code> for <code>second</code> <code>double</code> for <code>dsecond</code>	Elapsed real time in seconds

`mkl_get_cpu_clocks`

Returns elapsed CPU clocks.

Syntax

```
void mkl_get_cpu_clocks (unsigned MKL_INT64 *clocks);
```

Include Files

- `mkl.h`

Output Parameters

Name	Type	Description
<code>clocks</code>	<code>unsigned MKL_INT64</code>	Elapsed CPU clocks

Description

The `mkl_get_cpu_clocks` function returns the elapsed CPU clocks.

This may be useful when timing short intervals with high resolution. The `mkl_get_cpu_clocks` function is also applied in pairs like `second/dsecond`. Note that out-of-order code execution on IA-32 or Intel® 64 architecture processors may disturb the exact elapsed CPU clocks value a little bit, which may be important while measuring extremely short time intervals.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

`mkl_get_cpu_frequency`

Returns the current CPU frequency value in GHz.

Syntax

```
double mkl_get_cpu_frequency(void);
```

Include Files

- `mk1.h`

Description

The function `mk1_get_cpu_frequency` returns the current CPU frequency in GHz.

NOTE

The returned value may vary from run to run if power management or Intel® Turbo Boost Technology is enabled.

Return Values

Name	Type	Description
<i>freq</i>	double	Current CPU frequency value in GHz

`mk1_get_max_cpu_frequency`

Returns the maximum CPU frequency value in GHz.

Syntax

```
double mk1_get_max_cpu_frequency(void);
```

Include Files

- `mk1.h`

Description

The function `mk1_get_max_cpu_frequency` returns the maximum CPU frequency in GHz.

Return Values

Name	Type	Description
<i>freq</i>	double	Maximum CPU frequency value in GHz

`mk1_get_clocks_frequency`

Returns the frequency value in GHz based on constant-rate Time Stamp Counter.

Syntax

```
double mk1_get_clocks_frequency (void);
```

Include Files

- `mk1.h`

Description

The function `mk1_get_clocks_frequency` returns the CPU frequency value (in GHz) based on constant-rate Time Stamp Counter (TSC). Use of the constant-rate TSC ensures that each clock tick is constant even if the CPU frequency changes. Therefore, the returned frequency is constant.

NOTE

Obtaining the frequency may take some time when `mkl_get_clocks_frequency` is called for the first time. The same holds for functions `second/dsecnd`, which call `mkl_get_clocks_frequency`.

Return Values

Name	Type	Description
<code>freq</code>	double	Frequency value in GHz

See Also

[second/dsecnd](#)

Memory Management

This section describes the Intel MKL memory functions. See the *Intel® MKL User's Guide* for more memory usage information.

mkl_free_buffers

Frees unused memory allocated by the Intel MKL Memory Allocator.

Syntax

```
void mkl_free_buffers (void);
```

Include Files

- `mkl.h`

Description

To improve performance of Intel MKL, the Memory Allocator uses per-thread memory pools where buffers may be collected for fast reuse. The `mkl_free_buffers` function frees unused memory allocated by the Memory Allocator.

See the *Intel MKL User's Guide* for details.

You should call `mkl_free_buffers` after the last call to Intel MKL functions. In large applications, if you suspect that the memory may get insufficient, you may call this function earlier, but anticipate a drop in performance that may occur due to reallocation of buffers for subsequent calls to Intel MKL functions.

In a threaded application, avoid calling `mkl_free_buffers` from each thread because the function has a global effect. Call [mkl_thread_free_buffers](#) instead.

Usage of mkl_free_buffers with FFT Functions

```
DFTI_DESCRIPTOR_HANDLE hand1;
DFTI_DESCRIPTOR_HANDLE hand2;
void mkl_free_buffers(void);
. . . . .
/* Using MKL FFT */
Status = DftiCreateDescriptor(&hand1, DFTI_SINGLE, DFTI_COMPLEX, dim, m1);
Status = DftiCommitDescriptor(hand1);
Status = DftiComputeForward(hand1, s_array1);
. . . . .
Status = DftiCreateDescriptor(&hand2, DFTI_SINGLE, DFTI_COMPLEX, dim, m2);
Status = DftiCommitDescriptor(hand2);
```

```

. . . . .
Status = DftiFreeDescriptor(&hand1);
/* Do not call mkl_free_buffers() here because the hand2 descriptor will be corrupted! */
. . . . .
Status = DftiComputeBackward(hand2, s_array2));
Status = DftiFreeDescriptor(&hand2);
/* Here you finish using Intel MKL FFT */
/* Memory leak will be triggered by any memory control tool */
/* Use mkl_free_buffers() to avoid memory leaking */
mkl_free_buffers();

```

mkl_thread_free_buffers

Frees unused memory allocated by the Intel MKL Memory Allocator in the current thread.

Syntax

```
void mkl_thread_free_buffers (void);
```

Include Files

- mkl.h

Description

To improve performance of Intel MKL, the Memory Allocator uses per-thread memory pools where buffers may be collected for fast reuse. The `mkl_thread_free_buffers` function frees unused memory allocated by the Memory Allocator in the current thread only.

You should call `mkl_thread_free_buffers` after the last call to Intel MKL functions in the current thread. In large applications, if you suspect that the memory may get insufficient, you may call this function earlier, but anticipate a drop in performance that may occur due to reallocation of buffers for subsequent calls to Intel MKL functions.

See Also

[`mkl\_free\_buffers`](#)

mkl_disable_fast_mm

Turns off the Intel MKL Memory Allocator for Intel MKL functions to directly use the system `malloc/free` functions.

Syntax

```
int mkl_disable_fast_mm (void);
```

Include Files

- mkl.h

Description

The `mkl_disable_fast_mm` function turns the Intel MKL Memory Allocator off for Intel MKL functions to directly use the system `malloc/free` functions. Intel MKL Memory Allocator uses per-thread memory pools where buffers may be collected for fast reuse. The Memory Allocator is turned on by default for better performance. To turn it off, you can use the `mkl_disable_fast_mm` function or the `MKL_DISABLE_FAST_MM` environment variable (See the *Intel MKL User's Guide* for details.) Call `mkl_disable_fast_mm` before calling any Intel MKL functions that require allocation of memory buffers.

NOTE

Turning the Memory Allocator off negatively impacts performance of some Intel MKL routines, especially for small problem sizes.

Return Values

Name	Type	Description
<i>mm</i>	int	1 - The Memory Allocator is successfully turned off. 0 - Turning the Memory Allocator off failed.

mkl_mem_stat

Reports the status of the Intel MKL Memory Allocator.

Syntax

```
MKL_INT64 mkl_mem_stat (int* AllocatedBuffers);
```

Include Files

- mkl.h

Output Parameters

Name	Type	Description
<i>AllocatedBuffers</i>	int	The number of buffers allocated by Intel MKL.

Description

The function returns the number of buffers allocated by Intel MKL and the amount of memory in these buffers. Intel MKL can allocate the memory buffers internally or in a call to [mkl_malloc/mkl_calloc](#). If no buffers are allocated at the moment, the `mkl_mem_stat` function returns 0. Call `mkl_mem_stat` to check the Intel MKL memory status.

NOTE

If you free all the memory allocated in calls to `mkl_malloc` or `mkl_calloc` and then call `mkl_free_buffers`, a subsequent call to `mkl_mem_stat` normally returns 0.

Return Values

Name	Type	Description
<i>AllocatedBytes</i>	MKL_INT64	The amount of allocated memory (in bytes).

See Also

[Usage Example for the Memory Functions](#)

mkl_peak_mem_usage

Reports the peak memory allocated by the Intel MKL Memory Allocator.

Syntax

```
MKL_INT64 mkl_peak_mem_usage (int mode);
```

Include Files

- `mkl.h`

Input Parameters

Name	Type	Description
<i>mode</i>	<code>int</code>	Requested mode of the function's operation. Possible values: • <code>MKL_PEAK_MEM_ENABLE</code> - start gathering the peak memory data • <code>MKL_PEAK_MEM_DISABLE</code> - stop gathering the peak memory data • <code>MKL_PEAK_MEM</code> - return the peak memory • <code>MKL_PEAK_MEM_RESET</code> - return the peak memory and reset the counter to start gathering the peak memory data from scratch

Description

The `mkl_peak_mem_usage` function reports the peak memory allocated by the Intel MKL Memory Allocator.

Gathering the peak memory data is turned off by default. If you need to know the peak memory, explicitly turn the data gathering mode on by calling the function with the `MKL_PEAK_MEM_ENABLE` value of the parameter. Use the `MKL_PEAK_MEM` and `MKL_PEAK_MEM_RESET` values only when the data gathering mode is turned on. Otherwise the function returns -1. The data gathering mode leads to performance degradation, so when the mode is turned on, you can turn it off by calling the function with the `MKL_PEAK_MEM_DISABLE` value of the parameter.

-
- If Intel MKL is running in a threaded mode, the `mkl_peak_mem_usage` function may return different amounts of memory from run to run.
 - The function reports the peak memory for the entire application, not just for the calling thread.
-

Return Values

Name	Type	Description
<i>AllocatedBytes</i>	<code>MKL_INT64</code>	The peak memory allocated by the Memory Allocator (in bytes) or -1 in case of errors.

See Also

[Usage Example for the Memory Functions](#)

`mkl_malloc`

Allocates an aligned memory buffer.

Syntax

```
void* mkl_malloc (size_t alloc_size, int alignment);
```

Include Files

- `mk1.h`

Input Parameters

Name	Type	Description
<code>alloc_size</code>	<code>size_t</code>	Size of the buffer to be allocated.
<code>alignment</code>	<code>int</code>	Alignment of the buffer.

Description

The function allocates an `alloc_size`-byte buffer aligned on the `alignment`-byte boundary.

If `alignment` is not a power of 2, the 32-byte alignment is used.

Return Values

Name	Type	Description
<code>a_ptr</code>	<code>void*</code>	Pointer to the allocated buffer if <code>alloc_size</code> ≥ 1, NULL if <code>alloc_size</code> < 1.

See Also

[mkl_free](#)

[Usage Example for the Memory Functions](#)

`mkl_calloc`

Allocates and initializes an aligned memory buffer.

Syntax

```
void* mkl_calloc (size_t num, size_t size, int alignment);
```

Include Files

- `mk1.h`

Input Parameters

Name	Type	Description
<code>num</code>	<code>size_t</code>	The number of elements in the buffer to be allocated.
<code>size</code>	<code>size_t</code>	The size of the element.
<code>alignment</code>	<code>int</code>	Alignment of the buffer.

Description

The function allocates a `num*size`-byte buffer, aligned on the `alignment`-byte boundary, and initializes the buffer with zeros.

If `alignment` is not a power of 2, the 64-byte alignment is used.

Return Values

Name	Type	Description
<i>a_ptr</i>	void*	Pointer to the allocated buffer if <i>size</i> ≥ 1, NULL if <i>size</i> < 1.

See Also

[mkl_malloc](#)

[mkl_realloc](#)

[mkl_free](#)

[Usage Example for the Memory Functions](#)

mkl_realloc

Changes the size of memory buffer allocated by mkl_malloc/mkl_calloc.

Syntax

```
void* mkl_realloc (void *ptr, size_t size);
```

Include Files

- `mkl.h`

Input Parameters

Name	Type	Description
<i>ptr</i>	void*	Pointer to the memory buffer allocated by the <code>mkl_malloc</code> or <code>mkl_calloc</code> function or a NULL pointer.
<i>size</i>	size_t	New size of the buffer.

Description

The function changes the size of the memory buffer allocated by the `mkl_malloc` or `mkl_calloc` function to *size* bytes. The first bytes of the returned buffer up to the minimum of the old and new sizes keep the content of the input buffer. The returned memory buffer can have a different location than the input one. If *ptr* is NULL, the function works as `mkl_malloc`.

Return Values

Name	Type	Description
<i>a_ptr</i>	void*	Pointer to the re-allocated buffer.

See Also

[mkl_malloc](#)

[mkl_calloc](#)

[mkl_free](#)

[Usage Example for the Memory Functions](#)

mkl_free

Frees the aligned memory buffer allocated by mkl_malloc/mkl_calloc.

Syntax

```
void mkl_free (void *a_ptr);
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>a_ptr</i>	void*	Pointer to the buffer to be freed.

Description

The function frees the buffer pointed by *a_ptr* and allocated by the `mkl_malloc()` or `mkl_calloc()` function and does nothing if *a_ptr* is NULL.

See Also

[mkl_malloc](#)

[mkl_calloc](#)

[Usage Example for the Memory Functions](#)

mkl_set_memory_limit

On Linux, sets the limit of memory that Intel MKL can allocate for a specified type of memory.

Syntax

```
int mkl_set_memory_limit (int mem_type, size_t limit);
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>mem_type</i>	int	Type of memory to limit. Possible values: MKL_MEM_MCDRAM - Multi-Channel Dynamic Random Access Memory (MCDRAM) (for more details, see http://www.anandtech.com/show/8217/intels-knights-landing-coprocessor-detailed).
<i>limit</i>	size_t	Memory limit in megabytes.

Description

This function sets the limit for the amount of memory that Intel MKL can allocate for the specified memory type. The limit bounds both internal allocations (inside Intel MKL computation routines) and external allocations (in a call to `mkl_malloc`, `mkl_calloc`, or `mkl_realloc`). By default no limit is set for memory allocation.

Call `mkl_set_memory_limit` at most once, prior to calling any other Intel MKL function in your application except `mkl_set_interface_layer` and `mkl_set_threading_layer`.

- Allocation in MCDRAM requires `libmemkind` and `libjemalloc` dynamic libraries which are a part of Intel® Manycore Platform Software Package (Intel® MPSP) for Linux*.
- The `mkl_set_memory_limit` function takes precedence over the `MKL_FAST_MEMORY_LIMIT` environment variable.

Return Values

Type	Description
<code>int</code>	Status of the function completion: • 1 - the limit is set • 0 - the limit is not set

[Usage Example for the Memory Functions](#)

Usage Example for the Memory Functions

```
#include <stdio.h>
#include <mkl.h>

int main(void) {
    double *a, *b, *c;
    int n, i;
    double alpha, beta;
    MKL_INT64 AllocatedBytes;
    int N_AllocatedBuffers;

    alpha = 1.1; beta = -1.2;
    n = 1000;
    mkl_peak_mem_usage(MKL_PEAK_MEM_ENABLE);
    a = (double*)mkl_malloc(n*n*sizeof(double), 64);
    b = (double*)mkl_malloc(n*n*sizeof(double), 64);
    c = (double*)mkl_calloc(n*n, sizeof(double), 64);
    for (i=0; i<(n*n); i++) {
        a[i] = (double)(i+1);
        b[i] = (double)(-i-1);
    }

    dgemm("N", "N", &n, &n, &n, &alpha, a, &n, b, &n, &beta, c, &n);
    AllocatedBytes = mkl_mem_stat(&N_AllocatedBuffers);
    printf("\nDGEMM uses %d bytes in %d buffers", AllocatedBytes, N_AllocatedBuffers);

    mkl_free_buffers();
    mkl_free(a);
    mkl_free(b);
    mkl_free(c);

    AllocatedBytes = mkl_mem_stat(&N_AllocatedBuffers);
```

```

if (AllocatedBytes > 0) {
    printf("\nMKL memory leak!");
    printf("\nAfter mkl_free_buffers there are %d bytes in %d buffers",
        AllocatedBytes, N_AllocatedBuffers);
}
printf("\nPeak memory allocated by Intel MKL memory allocator %d bytes. Start to count new memory
peak",
    mkl_peak_mem_usage(MKL_PEAK_MEM_RESET));
a = (double*)mkl_malloc(n*n*sizeof(double), 64);
a = (double*)mkl_realloc(a, 2*n*n*sizeof(double));
mkl_free(a);
printf("\nPeak memory allocated by Intel MKL memory allocator after reset of peak memory counter %d
bytes\n",
    mkl_peak_mem_usage(MKL_PEAK_MEM));

return 0;
}

```

Single Dynamic Library Control

Intel® MKL provides the Single Dynamic Library (SDL), which enables setting the interface and threading layer for Intel MKL at run time. See *Intel® MKL User's Guide* for details of SDL and layered model concept. This section describes the functions supporting SDL.

mkl_set_interface_layer

Sets the interface layer for Intel MKL at run time. Use with the Single Dynamic Library.

Syntax

```
int mkl_set_interface_layer (int required_interface);
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>required_interface</i>	int	Determines the interface layer. Possible values depend on the system architecture. Some of the values are only available on Linux* OS: - Intel® 64 architecture: - MKL_INTERFACE_LP64 for the Intel LP64 interface. - MKL_INTERFACE_ILP64 for the Intel ILP64 interface. - MKL_INTERFACE_LP64+MKL_INTERFACE_GNU for the GNU* LP64 interface on Linux OS. - MKL_INTERFACE_ILP64+MKL_INTERFACE_GNU for the GNU ILP64 interface on Linux OS. - IA-32 architecture: - MKL_INTERFACE_LP64 for the Intel interface on Linux OS.

Name	Type	Description
		MKL_INTERFACE_LP64+MKL_INTERFACE_GNU or MKL_INTERFACE_GNU for the GNU interface on Linux OS.

Description

If you are using the Single Dynamic Library (SDL), the `mkl_set_interface_layer` function sets the specified interface layer for Intel MKL at run time.

Call this function prior to calling any other Intel MKL function in your application except `mkl_set_threading_layer`. You can call `mkl_set_interface_layer` and `mkl_set_threading_layer` in any order.

The `mkl_set_interface_layer` function takes precedence over the `MKL_INTERFACE_LAYER` environment variable.

See *Intel MKL User's Guide* for the layered model concept and usage details of the SDL.

Return Values

Type	Description
int	- Current interface layer if it is set in a call to <code>mkl_set_interface_layer</code> or specified by environment variables or defaults. Possible values are specified in Input Parameters. -1, if the layer was not specified prior to the call and the input parameter is incorrect.

mkl_set_threading_layer

Sets the threading layer for Intel MKL at run time. Use with the Single Dynamic Library (SDL).

Syntax

```
int mkl_set_threading_layer (int required_threading);
```

Include Files

- `mkl.h`

Input Parameters

Name	Type	Description
<code>required_threading</code>	int	Determines the threading layer. Possible values: <code>MKL_THREADING_INTEL</code> for Intel threading. <code>MKL_THREADING_SEQUENTIAL</code> for the sequential mode of Intel MKL. <code>MKL_THREADING_TBB</code> for threading with the Intel® Threading Building Blocks.

Name	Type	Description
		MKL_THREADING_PGI for PGI threading on Windows* or Linux* operating system only. Do not use this value with the SDL for Intel® Many Integrated Core (Intel® MIC) Architecture.
		MKL_THREADING_GNU for GNU threading on Linux* operating system only. Do not use this value with the SDL for Intel MIC Architecture.

Description

If you are using the Single Dynamic Library (SDL), the `mkl_set_threading_layer` function sets the specified threading layer for Intel MKL at run time.

Call this function prior to calling any other Intel MKL function in your application except `mkl_set_interface_layer`.

You can call `mkl_set_threading_layer` and `mkl_set_interface_layer` in any order.

The `mkl_set_threading_layer` function takes precedence over the `MKL_THREADING_LAYER` environment variable.

See *Intel MKL User's Guide* for the layered model concept and usage details of the SDL.

Return Values

Type	Description
int	- Current threading layer if it is set in a call to <code>mkl_set_threading_layer</code> or specified by environment variables or defaults. Possible values are specified in Input Parameters. -1, if the layer was not specified prior to the call and the input parameter is incorrect.

`mkl_set_xerbla`

Replaces the error handling routine. Use with the Single Dynamic Library on Windows OS.*

Syntax

```
XerblaEntry mkl_set_xerbla (XerblaEntry new_xerbla_ptr);
```

Include Files

- `mkl.h`

Input Parameters

Name	Type	Description
<code>new_xerbla_ptr</code>	XerblaEntry	Pointer to the error handling routine to be used.

Description

If you are linking with the Single Dynamic Library (SDL) `mkl_rt.lib` on Windows* OS, the `mkl_set_xerbla` function replaces the error handling routine that is called by Intel MKL functions with the routine specified by the parameter.

See *Intel MKL User's Guide* for details of SDL.

Return Values

The function returns the pointer to the replaced error handling routine.

See Also

[xerbla](#)

mkl_set_progress

Replaces the progress information routine. Use with the Single Dynamic Library (SDL) on Windows OS.*

Syntax

```
ProgressEntry mkl_set_progress (ProgressEntry new_progress_ptr);
```

Include Files

- `mkl.h`

Input Parameters

Name	Type	Description
<code>new_progress_ptr</code>	<code>ProgressEntry</code>	Pointer to the progress information routine to be used.

Description

If you are linking with the Single Dynamic Library (SDL) `mkl_rt.lib` on Windows* OS, the `mkl_set_progress` function replaces the currently used progress information routine with the routine specified by the parameter.

See *Intel MKL User's Guide* for details of SDL.

Return Values

The function returns the pointer to the replaced progress information routine.

See Also

[mkl_progress](#)

mkl_set_pardiso_pivot

Replaces the routine handling Intel MKL PARDISO pivots with a user-defined routine. Use with the Single Dynamic Library (SDL).

Syntax

```
PardisopivotEntry mkl_set_pardiso_pivot (PardisopivotEntry new_pardiso_pivot_ptr);
```

Include Files

- `mkl.h`

Input Parameters

Name	Type	Description
<code>new_pardiso_pivot_ptr</code>	<code>PardisopivotEntry</code>	Pointer to the pivot setting routine to be used.

Description

If you are using the Single Dynamic Library (SDL), the `mkl_set_pardiso_pivot` function replaces the pivot setting routine that is called by Intel MKL functions with the routine specified by the parameter.

See *Intel MKL User's Guide* for usage details of the SDL.

Return Values

Type	Description
<code>PardisopivotEntry</code>	Pointer to the replaced pivot setting routine.

See Also

[mkl_pardiso_pivot](#)

Intel Many Integrated Core Architecture Support

This section describes Intel MKL functions to support the use of Intel Xeon Phi coprocessors and especially Automatic Offload mode, when the computations are automatically offloaded to the coprocessors.

The `mkl_mic_enable` function enables Intel MKL to offload computations to Intel Xeon Phi coprocessors automatically, while the `mkl_mic_disable` function disables automatic offloading.

Important

Automatic Offload supports only OpenMP* threaded Intel MKL.

Optional work-division control functions enable you to specify the fractional amount of work to distribute between the host CPU and the coprocessors in the Automatic Offload mode. Work division is a fractional measure ranging from 0.0 to 1.0. For example, setting work division for the host CPU to 0.5 means to keep half of the computational work on the host CPU and move half to the coprocessor(s). Setting work division to 0.25 for a coprocessor means to offload a quarter of the computational work to this coprocessor while leaving the rest on the host CPU.

Other functions enable more control over computational resources of Intel Xeon Phi coprocessors.

NOTE

The support functions for Intel MIC Architecture take precedence over the respective environment variables.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

`mkl_mic_enable`

Enables Automatic Offload mode.

Syntax

```
int mkl_mic_enable();
```

Include Files

- `mkl.h`

Description

The `mkl_mic_enable` function enables Automatic Offload mode and initializes Intel Xeon Phi coprocessors available on your system. This function takes precedence over the `MKL_MIC_ENABLE` environment variable. Unlike the function, the environment variable enables Automatic Offload mode, but the initialization is delayed until a call to an Intel MKL function supporting Automatic Offload. For functions supporting Automatic Offload, see the *Intel MKL Release Notes*.

Return Values

Name	Type	Description
<code>ierr</code>	<code>int</code>	Result status: = 0 Indicates that Automatic Offload mode is successfully enabled. < 0 Indicates a failure to enable Automatic Offload mode.

`mkl_mic_disable`

Disables Automatic Offload mode.

Syntax

```
int mkl_mic_disable();
```

Include Files

- `mkl.h`

Description

The `mkl_mic_disable` function disables Automatic Offload mode. To enable Automatic Offload mode back, use the `mkl_mic_enable` function.

NOTE

If Automatic Offload mode is not enabled, a call to `mkl_mic_disable` completes successfully if Intel Xeon Phi coprocessors are available on your system.

Return Values

Name	Type	Description
<code>ierr</code>	<code>int</code>	Result status: = 0 Indicates that Automatic Offload mode is successfully disabled. < 0 Indicates a failure to disable Automatic Offload mode.

mkl_mic_get_device_count

Returns the number of Intel Xeon Phi coprocessors on the system when called on the host CPU.

Syntax

```
int mkl_mic_get_device_count();
```

Include Files

- mkl.h

Description

The `mkl_get_device_count` function returns the number of Intel Xeon Phi coprocessors on your system. You may need this number to specify a custom work-division scheme.

CAUTION

Call this function only on the host CPU.

Return Values

Name	Type	Description
<code>ndevices</code>	<code>int</code>	The number of Intel Xeon Phi coprocessors available on the system. Equals zero if there are none.

See Also

[mkl_mic_enable](#)

mkl_mic_set_workdivision

For computations in the Automatic Offload mode, sets the fraction of the work for the specified coprocessor or host CPU to do.

Syntax

```
int mkl_mic_set_workdivision (MKL_MIC_TARGET_TYPE target_type, int target_number,  
double wd);
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<code>target_type</code>	<code>MKL_MIC_TARGET_TYPE</code>	Type of the target device. Use one of the following values: • <code>MKL_TARGET_HOST</code> - host CPU • <code>MKL_TARGET_MIC</code> - Intel Xeon Phi coprocessor, default

Name	Type	Description
<code>target_number</code>	int	The device to set the fraction of work for. Takes the following values: • ≥ 0. Specifies execution on a specific coprocessor. The coprocessor is determined by <code>target_number</code> modulo the number of Intel Xeon Phi coprocessors on the system as returned by <code>mkl_mic_get_device_count()</code>. For example: for a system with 4 Intel Xeon Phi coprocessors, <code>target_number = 6</code> determines the coprocessor number 2. • < 0. Reserved. If <code>target_type = MKL_TARGET_HOST</code>, the function ignores the <code>target_number</code> parameter, which may have any value.
<code>wd</code>	double	The fractional amount of the work that the specified device should do, where $0.0 \leq wd \leq 1.0$. Specifying <code>MKL_MIC_AUTO_WORKDIVISION</code> for <code>wd</code> indicates that Intel MKL should determine the amount of the work for the specified device.

Description

If you are using Intel MKL in Automatic Offload mode, the `mkl_mic_set_workdivision` function specifies how much work each Intel Xeon Phi coprocessor or the host CPU should do. This function takes precedence over the `MKL_HOST_WORKDIVISION`, `MKL_MIC_WORKDIVISION`, and `MKL_MIC_<number>_WORKDIVISION` environment variables (see the *Intel MKL User's Guide* for details).

- Intel MKL interprets the fraction of work set by the `mkl_mic_set_workdivision` function as guidance toward dividing work between coprocessors, but the library may choose a different work division if necessary.
- Intel MKL resolves the collision that arises if the sum of all the work-division fractions does not equal one.
- For LAPACK routines, setting the fraction of work to any value other than 0.0 enables the specified processor for Automatic Offload mode. However Intel MKL LAPACK does not use the value specified to divide the workload. For example, setting the fraction to 0.5 has the same effect as setting the fraction to 1.0.

Return Values

Name	Type	Description
<code>ierr</code>	int	Result status: = 0 Indicates that the fraction is successfully set. < 0 Indicates a failure to set the fraction.

See Also

[mkl_mic_get_device_count](#)
[mkl_mic_enable](#)
[mkl_mic_get_workdivision](#)

mkl_mic_get_cpuinfo

mkl_mic_get_workdivision

For computations in the Automatic Offload mode, retrieves the fraction of the work for the specified coprocessor or host CPU to do.

Syntax

```
int mkl_mic_get_workdivision (MKL_MIC_TARGET_TYPE target_type, int target_number,
double *wd);
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>target_type</i>	MKL_MIC_TARGET_TYPE	Type of the target device. Use one of the following values: • MKL_TARGET_HOST - host CPU • MKL_TARGET_MIC - Intel Xeon Phi coprocessor, default
<i>target_number</i>	int	The device to retrieve the fraction of work for. Takes the following values: • ≥ 0. Specifies execution on a specific coprocessor. The coprocessor is determined by <i>target_number</i> modulo the number of Intel Xeon Phi coprocessors on the system as returned by <code>mkl_mic_get_device_count()</code>. For example: for a system with 4 Intel Xeon Phi coprocessors, <i>target_number</i> = 6 determines the coprocessor number 2. • < 0. Reserved. If <i>target_type</i> = MKL_TARGET_HOST, the function ignores the <i>target_number</i> parameter, which may have any value.

Output Parameters

Name	Type	Description
<i>wd</i>	double	The fractional amount of the work that the specified device should do, where $0.0 \leq wd \leq 1.0$. MKL_MIC_AUTO_WORKDIVISION set for <i>wd</i> indicates that Intel MKL should determine the amount of the work for the specified device.

Description

If you are using Intel MKL in the Automatic Offload mode, the `mkl_mic_get_workdivision` function provides you with the amount of the work that the specified coprocessor or host CPU is configured to do.

Return Values

Name	Type	Description
<i>ierr</i>	int	Result status: = 0 Indicates that the fraction is successfully returned. < 0 Indicates a failure to retrieve the fraction.

See Also

[mkl_mic_set_workdivision](#)

mkl_mic_set_max_memory

Sets the maximum amount of Intel Xeon Phi coprocessor memory reserved for the Automatic Offload computations.

Syntax

```
int mkl_mic_set_max_memory (MKL_MIC_TARGET_TYPE target_type, int target_number, size_t mem_size);
```

Include Files

- `mkl.h`

Input Parameters

Name	Type	Description
<i>target_type</i>	MKL_MIC_TARGET_TYPE	Type of the target device. Use the value of MKL_MIC_TARGET_MIC - Intel Xeon Phi coprocessor, default.
<i>target_number</i>	int	The coprocessor number for which the maximum memory used for Automatic Offload computations is set. Takes the following values: • ≥ 0. Specifies execution on a specific coprocessor. The coprocessor is determined by <i>target_number</i> modulo the number of Intel Xeon Phi coprocessors on the system as returned by <code>mkl_mic_get_device_count()</code>. For example: for a system with 4 Intel Xeon Phi coprocessors, <i>target_number</i> = 6 determines the coprocessor number 2. • <0. Reserved.
<i>mem_size</i>	size_t	For the <i>target_number</i> device, the amount of memory in kilobytes to reserve for Automatic Offload computations. Intel MKL attempts to not exceed the specified memory size for Automatic Offload computations.

Description

The `mkl_mic_set_max_memory` function enables you to limit coprocessor memory used by the Automatic Offload computations. Intel MKL reserves the specified memory on Intel Xeon Phi coprocessors. This can improve the performance of Automatic Offload computations by reducing the cost of buffer initialization and data transfer. The specified memory is reserved for the calling process, and the threads of a process share the specified memory. Intel MKL allocates additional memory for each process that performs Automatic Offload computations.

This function takes precedence over the `MKL_MIC_MAX_MEMORY` and `MKL_MIC_<number>_MAX_MEMORY` environment variables (see the *Intel MKL User's Guide* for details).

-
- Call `mkl_mic_set_max_memory` before any Intel MKL functions that do Automatic Offload computations.
 - Use `mkl_mic_free_memory` to free the coprocessor memory reserved for the Automatic Offload computations.
-

Return Values

Name	Type	Description
<code>ierr</code>	<code>int</code>	Result status: = 0 Indicates the coprocessor memory reserved for Automatic Offload is set successfully. < 0 Indicates an error.

See Also

[mkl_mic_free_memory](#)
[mkl_mic_enable](#)
[mkl_mic_get_meminfo](#)

mkl_mic_free_memory

Frees the coprocessor memory reserved for the Automatic Offload computations.

Syntax

```
int mkl_mic_free_memory (MKL_MIC_TARGET_TYPE target_type, int target_number);
```

Include Files

- `mkl.h`

Input Parameters

Name	Type	Description
<code>target_type</code>	<code>MKL_MIC_TARGET_TYPE</code>	Type of the target device. Use the value of <code>MKL_TARGET_MIC</code> - Intel Xeon Phi coprocessor, default.
<code>target_number</code>	<code>int</code>	The coprocessor number for which the memory reserved for Automatic Offload computations is freed. Takes the following values:

Name	Type	Description
		• ≥ 0. Specifies execution on a specific coprocessor. The coprocessor is determined by <i>target_number</i> modulo the number of Intel Xeon Phi coprocessors on the system as returned by <code>mkl_mic_get_device_count()</code>. For example: for a system with 4 Intel Xeon Phi coprocessors, <i>target_number</i> = 6 determines the coprocessor number 2. • < 0. Reserved.

Description

The `mkl_mic_free_memory` function frees the coprocessor memory reserved for the Automatic Offload computations. If you call `mkl_mic_set_max_memory` to specify the maximum coprocessor memory for Automatic Offload computations, Intel MKL reserves and reuses the specified coprocessor memory during multiple Automatic Offload calls. You can reclaim the coprocessor memory by calling `mkl_mic_free_memory`.

- Currently, Intel MKL reserves the coprocessor memory only if the `mkl_mic_set_max_memory` function is called. Therefore, `mkl_mic_free_memory` has no effect unless there is a prior call to the `mkl_mic_set_max_memory` function.
- If you do not call `mkl_mic_free_memory`, Intel MKL frees the coprocessor memory at the program exit.

Return Values

Name	Type	Description
<i>ierr</i>	int	Result status: = 0 Indicates the coprocessor memory reserved for Automatic Offload is freed successfully. < 0 Indicates an error.

See Also

[mkl_mic_set_max_memory](#)
[mkl_mic_enable](#)

`mkl_mic_register_memory`

Enables/disables the `mkl_malloc` function running in Automatic Offload mode to register allocated memory.

Syntax

```
void mkl_mic_register_memory (int control);
```

Include Files

- `mkl.h`

Input Parameters

Name	Type	Description
<i>control</i>	int	Desired behavior of <code>mkl_malloc</code> . Possible values: 0 - not register allocated memory, default. 1 - register allocated memory if Automatic Offload (AO) mode is enabled.

Description

The `mkl_mic_register_memory` function enables or disables the `mkl_malloc` function to register allocated memory when `mkl_malloc` runs in AO mode.

Registration of memory may reduce the overhead introduced by the operating system during data transfers between Intel Xeon Phi coprocessors and the host CPU.

This function takes precedence over the `MKL_MIC_REGISTER_MEMORY` environment variable.

If AO mode is disabled, the function has no effect.

See Also

[mkl_malloc](#) Allocates an aligned memory buffer.

[mkl_mic_enable](#) Enables Automatic Offload mode.

mkl_mic_set_device_num_threads

Sets the maximum number of OpenMP threads to use on an Intel Xeon Phi coprocessor for the Automatic Offload computations.*

Syntax

```
int mkl_mic_set_device_num_threads (MKL_MIC_TARGET_TYPE target_type, int target_number,
int num_threads);
```

Include Files

- `mkl.h`

Input Parameters

Name	Type	Description
<i>target_type</i>	MKL_MIC_TARGET_TYPE	Type of the target device. Use the value of <code>MKL_TARGET_MIC</code> - Intel Xeon Phi coprocessor, default.
<i>target_number</i>	int	The coprocessor number for which the maximum number of threads to be used for Automatic Offload computations is set. Takes the following values: • ≥ 0. Specifies execution on a specific coprocessor. The coprocessor is determined by <i>target_number</i> modulo the number of Intel Xeon Phi coprocessors on the system as returned by <code>mkl_mic_get_device_count()</code>.

Name	Type	Description
		For example: for a system with 4 Intel Xeon Phi coprocessors, <code>target_number = 6</code> determines the coprocessor number 2. • <0. Reserved.
<code>num_threads</code>	<code>int</code>	The number of threads to use for Automatic Offload computations on the <code>target_number</code> coprocessor. Must be greater than 0.

Description

The `mkl_mic_set_device_num_threads` function enables you to limit the number of OpenMP threads to use for Automatic Offload computations on a specific Intel Xeon Phi coprocessor.

This function takes precedence over the `MIC_OMP_NUM_THREADS` and `MKL_MIC_<number>_OMP_NUM_THREADS` environment variables (see the *Intel MKL User's Guide* for details).

Unless the maximum number of threads is set by the environment variables or this function, Intel MKL uses all coprocessor cores.

Call `mkl_mic_set_device_num_threads` before initialization of Automatic Offload mode. Otherwise the function returns -1 without setting the number of threads.

NOTE

Automatic Offload mode can be initialized as follows:

- *explicitly*, in a call to the `mkl_mic_enable` function.
- *implicitly*, in the first call to an Intel MKL function that does Automatic Offload computations (for example: `?GEMM`). See the *Intel MKL Release Notes* for which functions support Automatic Offload mode.

The `mkl_mic_set_device_num_threads` function sets the maximum number of threads to use for the Automatic Offload computations on Intel Xeon Phi coprocessors only. To control host CPU threading, use general threading control functions and see "Using Additional Threading Control" in the *Intel MKL User's Guide* for more information.

Return Values

Name	Type	Description
<code>ierr</code>	<code>int</code>	Result status: = 0 Indicates that the number of threads is set successfully. < 0 Indicates a failure to set the number of threads.

See Also

[mkl_mic_enable](#)
[Threading Control](#)

mkl_mic_set_resource_limit

For computations in the Automatic Offload mode, sets the maximum fraction of available Intel Xeon Phi coprocessor computational resources (cores) that the calling process can use.

Syntax

```
int mkl_mic_set_resource_limit (double fraction);
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>fraction</i>	double	The fractional amount of Intel Xeon Phi coprocessor computational resources that the calling process can use for Automatic Offload (AO). Possible values: $0.0 \leq \textit{fraction} \leq 1.0$. Special values: • 0.0 - you need to manage the coprocessors explicitly using the mkl_mic_set_device_num_threads function or the MIC_KMP_AFFINITY environment variable. Default. • MKL_MPI_PPN constant - enables a fully automated mode for message-passing interface (MPI) applications. In this mode, Intel MKL tries to read the number of MPI processes per node (<i>ppn</i>) from the environment variables passed to the process by MPI. If this attempt is successful, Intel MKL sets the actual value of the fractional amount to $1.0/\textit{ppn}$.

NOTE

For Intel® MPI Library, Open MPI, and IBM Platform MPI, Intel MKL automatically detects *ppn*. For other MPI implementations, use the MKL_MPI_PPN environment variable to set *ppn*.

Description

If you are using Intel MKL in the AO mode, the `mkl_mic_set_resource_limit` function specifies how much of the computational resources of Intel Xeon Phi coprocessors can be used by the calling process. Use this function if you need to share coprocessor cores automatically across multiple processes that call Intel MKL in the AO mode. For example, this might be useful in MPI applications.

You can also enable this functionality using the `MKL_MIC_RESOURCE_LIMIT` environment variable (see the *Intel MKL User's Guide* for details), but the `mkl_mic_set_resource_limit` function take precedence over the environment variable.

If *fraction* is set to a valid non-zero value, Intel MKL enables automatic reservation of Intel Xeon Phi coprocessor cores.

Actual reservation is made during a call to an Intel MKL AO function and works as follows:

1. Intel MKL converts *fraction* to a number of Intel Xeon Phi coprocessor cores and tries to find cores that are not reserved by other processes.

The number of available cores can be less than the requested number. Intel MKL considers cores of all available coprocessors as a single space and can find cores on different coprocessors. However, Intel MKL tends to reserve as many cores as were requested and to reserve cores compactly (using as few coprocessors as possible).

2. Intel MKL exclusively reserves cores found in the previous step.

Intel MKL makes reservation safely across a persistent shared memory region using semaphores.

3. Intel MKL performs AO computations on reserved cores only.

You do not need to set any threading parameters for Intel Xeon Phi coprocessors, such as `MIC_OMP_NUM_THREADS` or `MIC_KMP_AFFINITY` (these settings are ignored when automatic resource sharing is enabled).

4. Upon completion of an AO call, Intel MKL releases reserved cores.

Be aware of the following features of the automatic reservation:

- Execution of Intel MKL AO functions falls back to the host if Intel MKL fails to reserve the minimum number of Intel Xeon Phi coprocessor cores that provide a benefit over executing on the host.
- The last core of Intel Xeon Phi coprocessors cannot be reserved because it is used for system processes.
- Reservation works only within a space of a single user. In other words, Intel MKL cannot share Intel Xeon Phi coprocessor resources across processes from different users.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Examples

1. One Intel Xeon Phi coprocessor with 61 cores is available on the system. One process calls `mkl_mic_set_resource_limit(1.0)` and then calls `dgemm` in AO mode. As a result, 60 Intel Xeon Phi coprocessor cores are reserved at the beginning of AO `dgemm`. Then `mkl_mic_set_resource_limit(0.3)` is invoked and AO `dgemm` is called one more time. As a result, `dgemm` is run on 18 Intel Xeon Phi coprocessor cores. During this run of AO `dgemm`, another process calls `mkl_mic_set_resource_limit(1.0)` and invokes AO `dgetrf`. Because 18 cores are reserved by the first process, only 42 cores are reserved for AO `dgetrf`.
2. Two Intel Xeon Phi coprocessors with 61 cores each are available on the system. Three processes simultaneously call `mkl_mic_set_resource_limit(0.34)` and then call `dpotrf` in AO mode. As a result, one process receives 40 cores from coprocessor 1, another process receives 40 cores from coprocessor 2, and the remaining process is given 20 cores from each of the two coprocessors for a total of 40 cores.

3. Two Intel Xeon Phi coprocessors with 58 cores each are available on the system. The user sets `MKL_MIC_PPN=4` and runs an MPI application with 4 MPI ranks. The following sequence of functions is called in each MPI process:

```
mkl_mic_set_workdivision(MKL_TARGET_MIC, 2, 0.0);
mkl_mic_set_resource_limit(MKL_MIC_PPN);
MPI_Init(...);
//calls to Intel MKL AO functions;
MPI_Finalize(...);
```

As a result, actual *fraction* is set to 0.25 for each MPI process, and each MPI process receives 14 cores on Intel Xeon Phi coprocessor 1 (because the user excluded co-processor 2 from computations by setting zero workdivision for it).

Return Values

Name	Type	Description
<i>ierr</i>	int	Result status:
		= 0 Indicates that the fraction is set successfully.
		< 0 Indicates a failure to set the fraction.

[mkl_mic_get_device_count](#)

mkl_mic_get_resource_limit

For computations in the Automatic Offload mode, retrieves the maximum fraction of available Intel Xeon Phi coprocessor computational resources (cores) that the calling process can use.

Syntax

```
int mkl_mic_get_resource_limit (double* fraction);
```

Include Files

- `mkl.h`

Output Parameters

Name	Type	Description
<i>fraction</i>	double*	The fractional amount of Intel Xeon Phi coprocessor computational resources that the calling process can use for Automatic Offload (AO). Possible values: $0.0 \leq \textit{fraction} \leq 1.0$.

Description

If you are using Intel MKL in the AO mode, the `mkl_mic_get_resource_limit` function retrieves the fractional amount of Intel Xeon Phi coprocessor computational resources that can be used by the calling process.

Return Values

Name	Type	Description
<i>ierr</i>	int	Result status: = 0 Indicates that the fraction is successfully returned. < 0 Indicates a failure to return the fraction.

mkl_mic_set_offload_report

Turns on/off reporting of Automatic Offload profiling.

Syntax

```
int mkl_mic_set_offload_report (int enabled);
```

Include Files

- `mkl.h`

Input Parameters

Name	Type	Description
<i>enabled</i>	int	This parameter specifies whether to turn the reporting on or off. Takes values with boolean semantics: • 0 - Reporting of Automatic Offload profiling should be turned off. • 1 - Reporting of Automatic Offload profiling should be turned on.

Description

If the `OFFLOAD_REPORT` environment variable has the value of 1 or 2, the `mkl_mic_set_offload_report` function turns on/off reporting of the Automatic Offload profiling at run time. If the `OFFLOAD_REPORT` environment variable is not set or is set to a value different from 1 and 2, the function has no effect. If `OFFLOAD_REPORT` is set to 1 or 2, the reporting is turned on at a program startup. The `mkl_mic_set_offload_report` function does not change the reporting level or the value of the environment variable. Instead, it determines which Intel MKL functions called in the Automatic Offload mode produce profiling reports.

For details of the reporting level and `OFFLOAD_REPORT` environment variable, see the *Intel MKL User's Guide*.

Return Values

Name	Type	Description
<i>iprev</i>	int	The previous value that determined whether the reporting was on or off.

mkl_mic_set_flags

Sets flags to control the behavior of computations in the Automatic Offload mode.

Syntax

```
int mkl_mic_set_flags (int flags);
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>flags</i>	int	The settings requested: • MKL_MIC_DEFAULT_FLAGS - The default Automatic Offload (AO) mode, when computations fall back to host in the case of any AO error, such as lack of memory or other resources on the Intel Xeon Phi coprocessor. • MKL_MIC_DISABLE_HOST_FALLBACK - The mode when computations do not fall back to host in the case of an AO error, but the AO function immediately returns control to the calling program without completing the computations.

Description

This function sets flags to control the behavior of computations in the AO mode. Depending on the flags set, the AO program may silently return to the calling program in the case of an AO error. To check whether the AO call is successful, call the `mkl_mic_get_status` function and check whether the return value is non-negative. For more details of `mkl_mic_get_status` and in particular, for a sequence of function calls that enables checking the status of an AO call, see [mkl_mic_get_status](#).

Return Values

Name	Type	Description
<i>old_flags</i>	int	The previously set flags.

See Also

[mkl_mic_get_flags](#)

mkl_mic_get_flags

Retrieves flags that control the behavior of computations in the Automatic Offload mode.

Syntax

```
int mkl_mic_get_flags (void);
```

Include Files

- `mk1.h`

Description

This function retrieves flags that control the behavior of computations in the Automatic Offload (AO) mode. These flags are either the default flags for the AO mode or the flags set in a call to the `mk1_mic_set_flags` function.

NOTE

Depending on the flags set, the AO program may silently return to the calling program in the case of an AO error. To check whether the AO call is successful, call the `mk1_mic_get_status` function and check whether the return value is non-negative. For more details of `mk1_mic_get_status` and in particular, for a sequence of function calls that enables checking the status of an AO call, see [mk1_mic_get_status](#).

Return Values

Name	Type	Description
<code>flags</code>	<code>int</code>	The flags returned, which can be one of the following: • <code>MKL_MIC_DEFAULT_FLAGS</code> - The default AO mode, when computations fall back to host in the case of any AO error, such as lack of memory or other resources on the Intel Xeon Phi coprocessor. • <code>MKL_MIC_DISABLE_HOST_FALLBACK</code> - The mode when computations do not fall back to host in the case of an AO error, but the AO function immediately returns control to the calling program without completing the computations.

See Also

[mk1_mic_set_flags](#)

`mk1_mic_get_status`

For the Automatic Offload mode, returns the status of the latest call to an Intel MKL function.

Syntax

```
int mk1_mic_get_status (void);
```

Include Files

- `mk1.h`

Description

This function returns the status of the latest call to an Intel MKL function done in the Automatic Offload (AO) mode. The sign of the returned value characterizes the status of the AO computations at a high level:

- `= 0` - The computations completed successfully using AO
- `> 0` - The computations were done without using AO
- `< 0` - The computations were not completed at all

In an AO call to an Intel MKL function, offloading computations as expected may not be possible for various reasons, such as:

- Lack of available memory or computation cores on an Intel Xeon Phi coprocessor
- Incorrect environment settings (which result in a failure to locate or load a coprocessor driver or libraries)
- Communication error during data transfer to or from a coprocessor (for example, a remote process dies unexpectedly)
- Other unexpected error

The status returned helps you to find out the reason of offload failure.

Because the status is a thread-local value, to be able to check the status of an Intel MKL AO function, the following sequence of function calls in the same thread is required:

1. `mkl_mic_clear_status`
2. Intel MKL function
3. `mkl_mic_get_status`

Return Values

Name	Type

<code>status</code>	<code>int</code>

Description

The thread-local value of the status:

- `MKL_MIC_SUCESS (0)` - The computations successfully completed with offloading to Intel Xeon Phi coprocessors.
- `MKL_MIC_NOT_IMPL (1)` - The computations successfully completed only on the host because AO is not implemented for this function or for the combination of input parameters of the function.
- `MKL_MIC_HOST_FALLBACK (2)` - The computations successfully completed only on the host because AO could not start. Possible reasons: the environment path does not include required system libraries, resources are insufficient, memory allocation failed on a coprocessor, and so on.
- `MKL_MIC_DISABLED (3)` - The computations successfully completed only on the host because AO is disabled.
- `MKL_MIC_FAILED (-1)` - The computations were not completed. AO could start, but an error occurred during the computations. Note that the function output data may be corrupted in this case.
- `MKL_MIC_HOST_FALLBACK_DISABLED (-2)` - The computations were not completed because AO could not start. Possible reasons: the environment path does not include required system libraries, resources are insufficient, memory allocation failed on a coprocessor, and so on. Unlike `MKL_MIC_HOST_FALLBACK`, the `mkl_mic_get_status` function can return this status only if the `mkl_mic_set_flags` function disabled falling back to host. Unlike for `MKL_MIC_FAILED` status, the function input and output data remain untouched.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

[mkl_mic_set_flags](#)

[mkl_mic_clear_status](#)

mkl_mic_clear_status

For the Automatic Offload mode, clears the status of the latest call to an Intel MKL function.

Syntax

```
int mkl_mic_clear_status (void);
```

Include Files

- `mkl.h`

Description

This function clears the status of the latest call to an Intel MKL function done in the Automatic Offload (AO) mode. Call `mkl_mic_clear_status` before calling an Intel MKL function in the AO mode to be able to check the status of the AO call. Because the status is a thread-local value, getting the status for an Intel MKL function requires the following sequence of function calls in the same thread:

1. `mkl_mic_clear_status`
2. Intel MKL function
3. `mkl_mic_get_status`

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. [mkl_mic_get_status](#)

mkl_mic_get_meminfo

Retrieves the amount of total and free memory for the specified coprocessor or host CPU.

Syntax

```
int mkl_mic_get_meminfo (MKL_MIC_TARGET_TYPE target_type, int target_number, int* totalmem, int* freemem);
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>target_type</i>	MKL_MIC_TARGET_TYPE	Type of the target device. Use one of the following values: • MKL_TARGET_HOST - host CPU • MKL_TARGET_MIC - Intel Xeon Phi coprocessor, default
<i>target_number</i>	int	The device to retrieve the memory information for. Takes the following values: • ≥ 0. Specifies execution on a specific coprocessor. The coprocessor is determined by <i>target_number</i> modulo the number of Intel Xeon Phi coprocessors on the system as returned by <code>mkl_mic_get_device_count()</code>. For example: for a system with 4 Intel Xeon Phi coprocessors, <i>target_number</i> = 6 determines the coprocessor number 2. • < 0. Reserved. If <i>target_type</i> = MKL_TARGET_HOST, the function ignores the <i>target_number</i> parameter, which may have any value.

Output Parameters

Name	Type	Description
<i>totalmem</i>	int*	The total amount of memory on the target device in kilobytes.
<i>freemem</i>	int*	The amount of free memory available on the target device in kilobytes.

Description

Use this function to retrieve the amount of total and free memory (in kilobytes) available on an offload device or host CPU.

Return Values

Name	Type	Description
<i>ierr</i>	int	Result status: = 0 Indicates that the memory information for the target device is successfully returned. < 0 Indicates a failure to return the information.

See Also

mkl_mic_get_cpuidinfo

Retrieves the number of cores, hardware threads, and frequency for the specified coprocessor or host CPU.

Syntax

```
int mkl_mic_get_cpuidinfo (MKL_MIC_TARGET_TYPE target_type, int target_number, int*
ncores, int* nthreads, double* freq);
```

Include Files

- `mkl.h`

Input Parameters

Name	Type	Description
<i>target_type</i>	MKL_MIC_TARGET_TYPE	Type of the target device. Use one of the following values: • MKL_TARGET_HOST - host CPU • MKL_TARGET_MIC - Intel Xeon Phi coprocessor, default
<i>target_number</i>	int	The device to retrieve the information for. Takes the following values: • ≥ 0. Specifies execution on a specific coprocessor. The coprocessor is determined by <i>target_number</i> modulo the number of Intel Xeon Phi coprocessors on the system as returned by <code>mkl_mic_get_device_count()</code>. For example: for a system with 4 Intel Xeon Phi coprocessors, <i>target_number</i> = 6 determines the coprocessor number 2. • <0. Reserved. If <i>target_type</i> = MKL_TARGET_HOST, the function ignores the <i>target_number</i> parameter, which may have any value.

Output Parameters

Name	Type	Description
<i>ncores</i>	int*	The number of physical cores on the target device.
<i>nthreads</i>	int*	The number of hardware threads on the target device.
<i>freq</i>	double*	The frequency in Hz of the target device.

Description

Use this function to retrieve the number of cores, hardware threads, and frequency for the host CPU or an Intel Xeon Phi coprocessor.

Return Values

Name	Type	Description
<i>ierr</i>	int	Result status: = 0 Indicates that the information for the target device is successfully returned. < 0 Indicates a failure to return the information.

Conditional Numerical Reproducibility Control

The CNR mode of Intel MKL ensures bitwise reproducible results from run to run of Intel MKL functions on a fixed number of threads for a specific Intel instruction set architecture (ISA) under the following conditions:

- Calls to Intel MKL occur in a single executable
- The number of computational threads used by the library does not change in the run

Intel MKL offers both functions and environment variables to support conditional numerical reproducibility. See the *Intel MKL User's Guide* for more information on bitwise reproducible results of computations and for details about the environment variables.

The support functions enable you to configure the CNR mode and also provide information on the current and optimal CNR branch on your system. [Usage Examples for CNR Support Functions](#) illustrate usage of these functions.

Important

Call the functions that define the behavior of CNR before any of the math library functions that they control.

Intel MKL provides named constants for use as input and output parameters of the functions instead of integer values. See [Named Constants for CNR Control](#) for a list of the named constants.

Although you can configure the CNR mode using either the support functions or the environment variables, the functions offer more flexible configuration and control than the environment variables. Settings specified by the functions take precedence over the settings specified by the environment variables.

Use Intel MKL in the CNR mode only in case a need for bitwise reproducible results is critical. Otherwise, run Intel MKL as usual to avoid performance degradation.

While you can supply unaligned input and output data to Intel MKL functions running in the CNR mode, use of aligned data is recommended. Refer to [Reproducibility Conditions](#) for more details.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

mkl_cbwr_set

Configures the CNR mode of Intel MKL.

Syntax

```
int mkl_cbwr_set (int setting);
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>setting</i>	int	CNR branch to set. See Named Constants for CNR Control for a list of named constants that specify the settings.

Description

The `mkl_cbwr_set` function configures the CNR mode. In this release, it sets the CNR branch and turns on the CNR mode.

NOTE

Settings specified by the `mkl_cbwr_set` function take precedence over the settings specified by the `MKL_CBWR` environment variable.

Return Values

Name	Type	Description
<i>status</i>	int	The status of the function completion: • <code>MKL_CBWR_SUCCESS</code> - the function completed successfully. • <code>MKL_CBWR_ERR_INVALID_INPUT</code> - an invalid setting is requested.

Name	Type	Description
		• MKL_CBWR_ERR_UNSUPPORTED_BRANCH - the input value of the branch does not match the instruction set architecture (ISA) of your system. See Named Constants for CNR Control for more details. • MKL_CBWR_ERR_MODE_CHANGE_FAILURE - the <code>mkl_cbwr_set</code> function requested to change the current CNR branch after a call to some Intel MKL function other than a CNR function.

See Also

[Usage Examples for CNR Support Functions](#)

mkl_cbwr_get

Returns the current CNR settings.

Syntax

```
int mkl_cbwr_get (int option);
```

Include Files

- `mkl.h`

Input Parameters

Name	Type	Description
<i>option</i>	int	Specifies what kind of settings is requested. Named constants define possible values of <i>option</i>: • MKL_CBWR_BRANCH - indicates the setting of the CNR branch. • MKL_CBWR_ALL - indicates all CNR-related settings.

NOTE

This release supports no CNR settings other than branch.

Description

The `mkl_cbwr_get` function returns the requested CNR settings. If the function completes successfully and the CNR mode is turned on, `mkl_cbwr_get` returns the *specific* CNR branch.

NOTE

To turn the CNR mode on, use the `mkl_cbwr_set` function or environment variables. For more details, see the *Intel MKL User's Guide*.

Return Values

Name	Type	Description
<i>setting</i>	int	Requested CNR settings. See Named Constants for CNR Control for a list of named constants that specify the settings. If the value of the <i>option</i> parameter is not permitted, contains the <code>MKL_CBWR_ERR_INVALID_INPUT</code> error code.

mkl_cbwr_get_auto_branch

Automatically detects the CNR code branch for your platform.

Syntax

```
int mkl_cbwr_get_auto_branch (void);
```

Include Files

- `mkl.h`

Description

The `mkl_cbwr_get_auto_branch` function uses a run-time CPU check to return a CNR branch that is optimized for the processor where the program is currently running.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Return Values

Name	Type	Description
<i>setting</i>	int	Automatically detected CNR branch. May be any <i>specific</i> branch listed in Named Constants for CNR Control .

See Also

[Usage Examples for CNR Support Functions](#)

Named Constants for CNR Control

Intel MKL provides reproducible results for a certain code branch, determined by the instruction set architecture (ISA). To define CNR code branches, use the following named constants as input/output for conditional numerical reproducibility support functions. Pass named constants to the functions instead of their values.

Named Constant	Value	Description
MKL_CBWR_AUTO	2	CNR mode uses the standard ISA-based dispatching model while ensuring fixed cache sizes, deterministic reductions, and static scheduling CNR mode uses the branch for the following ISA:
MKL_CBWR_COMPATIBLE	3	Intel® Streaming SIMD Extensions 2 (Intel® SSE2) without rcpps/rsqrtps instructions
MKL_CBWR_SSE2	4	Intel SSE2
MKL_CBWR_SSE3	5	DEPRECATED. Intel® Streaming SIMD Extensions 3 (Intel® SSE3). This setting is kept for backward compatibility and is equivalent to MKL_CBWR_SSE2.
MKL_CBWR_SSSE3	6	Supplemental Streaming SIMD Extensions 3 (SSSE3)
MKL_CBWR_SSE4_1	7	Intel® Streaming SIMD Extensions 4-1 (SSE4-1)
MKL_CBWR_SSE4_2	8	Intel® Streaming SIMD Extensions 4-2 (SSE4-2)
MKL_CBWR_AVX	9	Intel® Advanced Vector Extensions (Intel® AVX)
MKL_CBWR_AVX2	10	Intel® Advanced Vector Extensions 2 (Intel® AVX2)

When specifying the CNR branch with the named constants, be aware of the following:

- Reproducible results are provided under [Reproducibility Conditions](#).
- Settings other than MKL_CBWR_AUTO or MKL_CBWR_COMPATIBLE are available only for Intel processors.
- Intel and Intel compatible CPUs have a few instructions, such as approximation instructions rcpps/rsqrtps, that may return different results. Setting the branch to MKL_CBWR_COMPATIBLE ensures that Intel MKL does not use these instructions and forces a single Intel SSE2 only code path to be executed.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Reproducibility Conditions

To get reproducible results from run to run, ensure that the number of threads is fixed and constant. Specifically:

- If you are running your program with OpenMP* parallelization on different processors, explicitly specify the number of threads.
 - To ensure that your application has deterministic behavior with OpenMP* parallelization and does not adjust the number of threads dynamically at run time, set `MKL_DYNAMIC` and `OMP_DYNAMIC` to `FALSE`. This is especially needed if you are running your program on different systems.
 - If you are running your program with the Intel® Threading Building Blocks parallelization, numerical reproducibility is not guaranteed.
-
- As usual, you should align your data, even in CNR mode, to obtain the best possible performance. While CNR mode also fully supports unaligned input and output data, the use of it might reduce the performance of some Intel MKL functions on earlier Intel processors. To ensure proper alignment of arrays, allocate memory for them using `mkl_malloc/mkl_calloc`.
 - Conditional Numerical Reproducibility does not ensure that bitwise-identical NaN values are generated when the input data contains NaN values.
 - If dynamic memory allocation fails on one run but succeeds on another run, you may fail to get reproducible results between these two runs.
-

Usage Examples for CNR Support Functions

The following examples illustrate usage of support functions for conditional numerical reproducibility.

Setting Automatically Detected CNR Branch

```
#include <mkl.h>
int main(void) {
    int my_cbwr_branch;
    /* Find the available MKL_CBWR_BRANCH automatically */
    my_cbwr_branch = mkl_cbwr_get_auto_branch();
    /* User code without Intel MKL calls */
    /* Piece of the code where CNR of Intel MKL is needed */
    /* The performance of Intel MKL functions might be reduced for CNR mode */
    if (mkl_cbwr_set(my_cbwr_branch) != MKL_CBWR_SUCCESS) {
        printf("Error in setting MKL_CBWR_BRANCH! Aborting...\n");
        return;
    }
    /* CNR calls to Intel MKL + any other code */
}
```

Use of the mkl_cbwr_get Function

```
#include <mkl.h>
int main(void) {
    int my_cbwr_branch;
    /* Piece of the code where CNR of Intel MKL is analyzed */
    my_cbwr_branch = mkl_cbwr_get(MKL_CBWR_BRANCH);
    switch (my_cbwr_branch) {
        case MKL_CBWR_AUTO:
```

```

        /* actions in case of automatic mode */
        break;
    case MKL_CBWR_SSSE3:
        /* actions for SSSE3 code */
        break;
    default:
        /* all other cases */
}
/* User code */
}

```

Miscellaneous

mkl_progress

Provides progress information.

Syntax

```
int mkl_progress (int* thread, int* step, char* stage, int lstage);
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>thread</i>	const int*	Pointer to the number of the OpenMP thread the progress routine is called from. 0 is passed for sequential code.
<i>step</i>	const int*	Pointer to the linear progress indicator that shows the amount of work done. Increases from 0 to the linear size of the problem during the computation.
<i>stage</i>	const char*	Message indicating the name of the routine or the name of the computation stage the progress routine is called from.
<i>lstage</i>	int	The length of a stage string excluding the trailing NULL character.

Description

The `mkl_progress` function is intended to track progress of a lengthy computation and/or interrupt the computation. By default this routine does nothing but the user application can redefine it to obtain the computation progress information. You can set it to perform certain operations during the routine computation, for instance, to print a progress indicator. A non-zero return value may be supplied by the redefined function to break the computation.

The progress function `mkl_progress` is regularly called from some LAPACK and DSS/PARDISO functions during the computation. Refer to a specific LAPACK or DSS/PARDISO function description to see whether the function supports this feature or not. If a LAPACK function returns `info=-1002`, the function was interrupted by `mkl_progress`.

WARNING

The `mkl_progress` function only supports OpenMP* threading and sequential execution.

Return Values

Name	Type	Description
<code>stopflag</code>	<code>int</code>	The stopping flag. A non-zero flag forces the routine to be interrupted. The zero flag is the default return value.

Example

The following example prints the progress information to the standard output device:

```
#include <stdio.h>
#include <string.h>
#define BUFLen 16
int mkl_progress( int* ithr, int* step, char* stage, int lstage )
{
    char buf[BUFLen];
    if( lstage >= BUFLen ) lstage = BUFLen-1;
    strncpy( buf, stage, lstage );
    buf[lstage] = '\0';
    printf( "In thread %i, at stage %s, steps passed %i\n", *ithr, buf, *step );
    return 0;
}
```

mkl_enable_instructions

Enables dispatching for new Intel® architectures.

Syntax

```
int mkl_enable_instructions (int isa);
```

Include Files

- `mkl.h`

Input Parameters

Name	Type	Description
<code>isa</code>	<code>int</code>	The Intel instruction-set architecture (ISA) for which to enable dispatching. Possible values: <code>MKL_ENABLE_AVX512</code> - Requests to enable dispatching Intel® Advanced Vector Extensions 512 (Intel® AVX-512) on Intel® Xeon® processors.

For more information about the Intel AVX-512 instructions, refer to <https://software.intel.com/en-us/blogs/2013/avx-512-instructions>.

Description

If automatic dispatching is not yet enabled for the specified ISA, `mkl_enable_instructions` enables Intel MKL to dispatch the instruction set to Intel® processors when the library runs on hardware (or simulation) that supports this instruction set.

You can also enable dispatching of new Intel architectures using the `MKL_ENABLE_INSTRUCTIONS` environment variable (for more details, see the *Intel MKL User's Guide*), but the settings specified by the `mkl_enable_instructions` function take precedence over the settings specified by the environment variable.

Return Values

Name	Type	Description
<code>irc</code>	<code>int</code>	Usage status of the specified instruction set: 1 - Intel MKL uses the specified instruction set if the hardware supports it. 0 - The request is rejected. Most likely, <code>mkl_enable_instructions</code> has been called after another Intel MKL function.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

`mkl_set_env_mode`

Sets up the mode that ignores environment settings specific to Intel MKL.

Syntax

```
int mkl_set_env_mode(int mode);
```

Include Files

- `mkl.h`

Input Parameters

Name	Type	Description
<code>mode</code>	<code>int</code>	Specifies what mode to set. For details, see Description . Possible values: • 0 - Do nothing. Use this value to query the current environment mode. • 1 - Make Intel MKL ignore environment settings specific to the library.

Description

In the default *environment mode*, Intel MKL can control its behavior using environment variables for threading, memory management, Conditional Numerical Reproducibility, automatic offload, and so on. The `mkl_set_env_mode` function sets up the environment mode that ignores all settings specified by Intel MKL environment variables except `MIC_LD_LIBRARY_PATH` and `MKLROOT`.

Return Values

Name	Type	Description
<code>current_mode</code>	<code>int</code>	Environment mode that was used before the function call: • 0 - Default • 1 - Ignore environment settings specific to Intel MKL.

`mkl_verbose`

Enables or disables Intel MKL Verbose mode.

Syntax

```
int mkl_verbose (int enable);
```

Include Files

- `mkl.h`

Input Parameters

Name	Type	Description
<code>enable</code>	<code>int</code>	Desired state of the Intel MKL Verbose mode. Indicates whether printing Intel MKL function call information should be turned on or off. Possible values: • 0 - disable the Verbose mode. • 1 - enable the Verbose mode.

Description

This function enables or disables the Intel MKL Verbose mode, in which computational functions print call description information. For details of the Verbose mode, see the *Intel MKL User's Guide*, available in the Intel® Software Documentation Library.

NOTE

The setting for the Verbose mode specified by the `mkl_verbose` function takes precedence over the setting specified by the `MKL_VERBOSE` environment variable.

Return Values

Name	Type	Description
<code>status</code>	<code>int</code>	• If the requested operation completed successfully, contains previous state of the verbose mode: • 0 - disabled

Name	Type	Description
		• 1 - enabled • If the function failed to complete the operation because of an incorrect input parameter, equals -1.

mkl_set_mpi

Sets the implementation of the message-passing interface to be used by Intel MKL.

Syntax

```
int mkl_set_mpi (int vendor, const char *custom_library_name);
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>vendor</i>	int	Specifies the implementation of the message-passing interface (MPI) to use: Possible values: • MKL_BLACS_CUSTOM - a custom MPI library. Requires a prebuilt custom MPI BLACS library. • MKL_BLACS_MSMPPI - Microsoft MPI library. • MKL_BLACS_INTELMPI - Intel® MPI library. • MKL_BLACS_MPICH - MPICH MPI library.
<i>custom_library_name</i>	const char *	The filename (without a directory name) of the custom BLACS dynamic library to use. This library must be located in the directory with your application executable or with Intel MKL dynamic libraries. Can be NULL or an empty string.

Description

Call this function to set the MPI implementation to be used by Intel MKL on Windows* OS when dynamic Intel MKL libraries are used. For all other configurations, the function returns an error indicating that you cannot set the MPI implementation. You can specify your own prebuilt dynamic BLACS library for a custom MPI by setting *vendor* to MKL_BLACS_CUSTOM and optionally passing the name of the custom BLACS dynamic library. If the *custom_library_path* parameter is NULL or an empty string, Intel MKL uses the default platform-specific library name: mkl_blacs_custom_lp64.dll or mkl_blacs_custom_ilp64.dll, depending on whether the BLACS interface linked against your application is LP64 or ILP64.

Return Values

Name	Type	Description
<code>status</code>	<code>int</code>	The return status: • 0 - The function completed successfully. • -1 - The <code>vendor</code> parameter is invalid. • -2 - The <code>custom_library_name</code> parameter is invalid. • -3 - The MPI library cannot be set at this point.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

mkl_finalize

Terminates Intel MKL execution environment and frees resources allocated by the library.

Syntax

```
void mkl_finalize(void);
```

Include Files

- `mkl.h`

Description

This function frees resources allocated by Intel MKL. Once this function is called, the application can no longer call Intel MKL functions other than `mkl_finalize`.

In particular, the `mkl_finalize` function enables you to free resources when a third-party shared library is statically linked to Intel MKL. To avoid resource leaks that may happen when a shared library is loaded and unloaded multiple times, call `mkl_finalize` each time the library is unloaded. The recommended method to do this depends on the operating system:

- On Linux* or OS X*, place the call into a shared library destructor.
- On Windows*, call `mkl_finalize` from the `DLL_PROCESS_DETACH` handler of `DllMain`.

NOTE

Intel MKL shared libraries automatically perform finalization when they are unloaded. If an application is statically linked to Intel MKL, the operating system frees all resources allocated by Intel MKL during termination of the process associated with the application.

BLACS Routines

This chapter describes the Intel® Math Kernel Library implementation of FORTRAN 77 routines from the BLACS (Basic Linear Algebra Communication Subprograms) package. These routines are used to support a linear algebra oriented message passing interface that may be implemented efficiently and uniformly across a large range of distributed memory platforms.

The BLACS routines make linear algebra applications both easier to program and more portable. For this purpose, they are used in Intel MKL intended for the Linux* and Windows* OSs as the communication layer of ScaLAPACK and Cluster FFT.

On computers, a linear algebra matrix is represented by a two dimensional array (2D array), and therefore the BLACS operate on 2D arrays. See description of the basic [matrix shapes](#) in a special section.

The BLACS routines implemented in Intel MKL are of four categories:

- Combines
- Point to Point Communication
- Broadcast
- Support.

The [Combines](#) take data distributed over processes and combine the data to produce a result. The [Point to Point](#) routines are intended for point-to-point communication and [Broadcast](#) routines send data possessed by one process to all processes within a scope.

The [Support routines](#) perform distinct tasks that can be used for initialization, destruction, information, and miscellaneous tasks.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Matrix Shapes

The BLACS routines recognize the two most common classes of matrices for dense linear algebra. The first of these classes consists of general rectangular matrices, which in machine storage are 2D arrays consisting of m rows and n columns, with a leading dimension, lda , that determines the distance between successive columns in memory.

The *general rectangular* matrices take the following parameters as input when determining what array to operate on:

m	(input) INTEGER. The number of matrix rows to be operated on.
n	(input) INTEGER. The number of matrix columns to be operated on.
a	(input/output) TYPE (depends on routine), array of dimension (lda, n) . A pointer to the beginning of the (sub)array to be sent.

lda (input) INTEGER. The distance between two elements in matrix row.

The second class of matrices recognized by the BLACS are *trapezoidal* matrices (triangular matrices are a sub-class of trapezoidal). Trapezoidal arrays are defined by m , n , and *lda*, as above, but they have two additional parameters as well. These parameters are:

uplo (input) CHARACTER*1 . Indicates whether the matrix is upper or lower trapezoidal, as discussed below.

diag (input) CHARACTER*1 . Indicates whether the diagonal of the matrix is unit diagonal (will not be operated on) or otherwise (will be operated on).

The shape of the trapezoidal arrays is determined by these parameters as follows:

Trapezoidal Arrays Shapes

The packing of arrays, if required, so that they may be sent efficiently is hidden, allowing the user to concentrate on the logical matrix, rather than on how the data is organized in the system memory.

Repeatability and Coherence

Floating point computations are not exact on almost all modern architectures. This lack of precision is particularly problematic in parallel operations. Since floating point computations are inexact, algorithms are classified according to whether they are *repeatable* and to what degree they guarantee *coherence*.

- Repeatable: a routine is repeatable if it is guaranteed to give the same answer if called multiple times with the same parallel configuration and input.
- Coherent: a routine is coherent if all processes selected to receive the answer get identical results.

NOTE

Repeatability and coherence do not effect correctness. A routine may be both incoherent and non-repeatable, and still give correct output. But inaccuracies in floating point calculations may cause the routine to return differing values, all of which are equally valid.

Repeatability

Because the precision of floating point arithmetic is limited, it is not truly associative: $(a + b) + c$ might not be the same as $a + (b + c)$. The lack of exact arithmetic can cause problems whenever the possibility for reordering of floating point calculations exists. This problem becomes prevalent in parallel computing due to race conditions in message passing. For example, consider a routine which sums numbers stored on different processes. Assume this routine runs on four processes, with the numbers to be added being the process numbers themselves. Therefore, process 0 has the value 0:0, process 1 has the value 1:0, and so on.

One algorithm for the computation of this result is to have all processes send their process numbers to process 0; process 0 adds them up, and sends the result back to all processes. So, process 0 would add a number to 0:0 in the first step. If receiving the process numbers is ordered so that process 0 always receives the message from process 1 first, then 2, and finally 3, this results in a repeatable algorithm, which evaluates the expression $((0:0 + 1:0) + 2:0) + 3:0$.

However, to get the best parallel performance, it is better not to require a particular ordering, and just have process 0 add the first available number to its value and continue to do so until all numbers have been added in. Using this method, a race condition occurs, because the order of the operation is determined by the order in which process 0 receives the messages, which can be effected by any number of things. This implementation is not repeatable, because the answer can vary between invocations, even if the input is the same. For instance, one run might produce the sequence $((0:0 + 1:0) + 2:0) + 3:0$, while a subsequent run could produce $((0:0 + 2:0) + 1:0) + 3:0$. Both of these results are correct summations of the given numbers, but because of floating point roundoff, they might be different.

Coherence

A routine produces coherent output if all processes are guaranteed to produce the exact same results. Obviously, almost no algorithm involving communication is coherent if communication can change the values being communicated. Therefore, if the parallel system being studied cannot guarantee that communication between processes preserves values, no routine is guaranteed to produce coherent results.

If communication is assumed to be coherent, there are still various levels of coherent algorithms. Some algorithms guarantee coherence only if floating point operations are done in the exact same order on every node. This is *homogeneous coherence*: the result will be coherent if the parallel machine is homogeneous in its handling of floating point operations.

A stronger assertion of coherence is *heterogeneous coherence*, which does not require all processes to have the same handling of floating point operations.

In general, a routine that is homogeneous coherent performs computations redundantly on all nodes, so that all processes get the same answer only if all processes perform arithmetic in the exact same way, whereas a routine which is heterogeneous coherent is usually constrained to having one process calculate the final result, and broadcast it to all other processes.

Example of Incoherence

An incoherent algorithm is one which does not guarantee that all processes get the same result even on a homogeneous system with coherent communication. The previous example of summing the process numbers demonstrates this kind of behavior. One way to perform such a sum is to have every process broadcast its number to all other processes. Each process then adds these numbers, starting with its own. The calculations performed by each process receives would then be:

- Process 0 : $((0:0 + 1:0) + 2:0) + 3:0$
- Process 1 : $((1:0 + 2:0) + 3:0) + 0:0$
- Process 2 : $((2:0 + 3:0) + 0:0) + 1:0$
- Process 3 : $((3:0 + 0:0) + 1:0) + 0:0$

All of these results are equally valid, and since all the results might be different from each other, this algorithm is incoherent. Notice, however, that this algorithm is repeatable: each process will get the same result if the algorithm is called again on the same data.

Example of Homogeneous Coherence

Another way to perform this summation is for all processes to send their data to all other processes, and to ensure the result is not incoherent, enforce the ordering so that the calculation each node performs is $((0:0 + 1:0) + 2:0) + 3:0$. This answer is the same for all processes only if all processes do the floating point arithmetic in the same way. Otherwise, each process may make different floating point errors during the addition, leading to incoherence of the output. Notice that since there is a specific ordering to the addition, this algorithm is repeatable.

Example of Heterogeneous Coherence

In the final example, all processes send the result to process 0, which adds the numbers and broadcasts the result to the rest of the processes. Since one process does all the computation, it can perform the operations in any order and it will give coherent results as long as communication is itself coherent. If a particular order is not forced on the the addition, the algorithm will not be repeatable. If a particular order is forced, it will be repeatable.

Summary

Repeatability and coherence are separate issues which may occur in parallel computations. These concepts may be summarized as:

- Repeatability: The routine will yield the exact same result if it run multiple times on an identical problem. Each process may get a different result than the others (i.e., repeatability does not imply coherence), but that value will not change if the routine is invoked multiple times.
- Homogeneous coherence: All processes selected to possess the result will receive the exact same answer if:
 - Communication does not change the value of the communicated data.
 - All processes perform floating point arithmetic exactly the same.
- Heterogeneous coherence: All processes will receive the exact same answer if communication does not change the value of the communicated data.

In general, lack of the associative property for floating point calculations may cause both incoherence and non-repeatability. Algorithms that rely on redundant computations are at best homogeneous coherent, and algorithms in which one process broadcasts the result are heterogeneous coherent. Repeatability does not imply coherence, nor does coherence imply repeatability.

Since these issues do not effect the correctness of the answer, they can usually be ignored. However, in very specific situations, these issues may become very important. A stopping criteria should not be based on incoherent results, for instance. Also, a user creating and debugging a parallel program may wish to enforce repeatability so the exact same program sequence occurs on every run.

In the BLACS, coherence and repeatability apply only in the context of the combine operations. As mentioned above, it is possible to have communication which is incoherent (for instance, two machines which store floating point numbers differently may easily produce incoherent communication, since a number stored on machine A may not have a representation on machine B). However, the BLACS cannot control this issue. Communication is assumed to be coherent, which for communication implies that it is also repeatable.

For combine operations, the BLACS allow you to set flags indicating that you would like combines to be repeatable and/or heterogeneous coherent (see [blacs_get](#) and [blacs_set](#) for details on setting these flags).

If the BLACS are instructed to guarantee heterogeneous coherency, the BLACS restrict the topologies which can be used so that one process calculates the final result of the combine, and if necessary, broadcasts the answer to all other processes.

If the BLACS are instructed to guarantee repeatability, orderings will be enforced in the topologies which are selected. This may result in loss of performance which can range from negligible to serious depending on the application.

A couple of additional notes are in order. Incoherence and nonrepeatability can arise as a result of floating point errors, as discussed previously. This might lead you to suspect that integer calculations are always repeatable and coherent, since they involve exact arithmetic. This is true if overflow is ignored. With overflow taken into consideration, even integer calculations can display incoherence and non-repeatability. Therefore, if the repeatability or coherence flags are set, the BLACS treats integer combines the same as floating point combines in enforcing repeatability and coherence guards.

By their nature, maximization and minimization should always be repeatable. In the complex precisions, however, the real and imaginary parts must be combined in order to obtain a magnitude value used to do the comparison (this is typically $|r| + |i|$ or $\text{sqr}(r^2 + i^2)$). This allows for the possibility of heterogeneous incoherence. The BLACS therefore restrict which topologies are used for maximization and minimization in the complex routines when the heterogeneous coherence flag is set.

BLACS Combine Operations

This section describes BLACS routines that combine the data to produce a result.

In a combine operation, each participating process contributes data that is combined with other processes' data to produce a result. This result can be given to a particular process (called the *destination* process), or to all participating processes. If the result is given to only one process, the operation is referred to as a *leave-on-one* combine, and if the result is given to all participating processes the operation is referenced as a *leave-on-all* combine.

At present, three kinds of combines are supported. They are:

- element-wise summation
- element-wise absolute value maximization
- element-wise absolute value minimization

of general rectangular arrays.

Note that a combine operation combines data between processes. By definition, a combine performed across a scope of only one process does not change the input data. This is why the operations (*max/min/sum*) are specified as *element-wise*. Element-wise indicates that each element of the input array will be combined with the corresponding element from all other processes' arrays to produce the result. Thus, a 4 x 2 array of inputs produces a 4 x 2 answer array.

When the *max/min* comparison is being performed, absolute value is used. For example, -5 and 5 are equivalent. However, the returned value is unchanged; that is, it is not the absolute value, but is a signed value instead. Therefore, if you performed a BLACS absolute value maximum combine on the numbers -5, 3, 1, 8 the result would be -8.

The initial symbol ? in the routine names below masks the data type:

i	integer
s	single precision real
d	double precision real
c	single precision complex
z	double precision complex.

BLACS Combines

Routine name	Results of operation
gamx2d	Entries of result matrix will have the value of the greatest absolute value found in that position.
gamn2d	Entries of result matrix will have the value of the smallest absolute value found in that position.

Routine name	Results of operation
gsum2d	Entries of result matrix will have the summation of that position.

?gamx2d

Performs element-wise absolute value maximization.

Syntax

```
call igamx2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest )
call sgamx2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest )
call dgamx2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest )
call cgamx2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest )
call zgamx2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>scope</i>	CHARACTER*1. Indicates what scope the combine should proceed on. Limited to ROW, COLUMN, or ALL.
<i>top</i>	CHARACTER*1. Communication pattern to use during the combine operation.
<i>m</i>	INTEGER. The number of matrix rows to be combined.
<i>n</i>	INTEGER. The number of matrix columns to be combined.
<i>a</i>	TYPE array (<i>lda</i> , <i>n</i>). Matrix to be compared with to produce the maximum.
<i>lda</i>	INTEGER. The leading dimension of the matrix <i>A</i> , that is, the distance between two successive elements in a matrix row.
<i>rcflag</i>	INTEGER. If <i>rcflag</i> = -1, the arrays <i>ra</i> and <i>ca</i> are not referenced and need not exist. Otherwise, <i>rcflag</i> indicates the leading dimension of these arrays, and so must be $\geq m$.
<i>rdest</i>	INTEGER. The process row coordinate of the process that should receive the result. If <i>rdest</i> or <i>cdest</i> = -1, all processes within the indicated scope receive the answer.
<i>cdest</i>	INTEGER. The process column coordinate of the process that should receive the result. If <i>rdest</i> or <i>cdest</i> = -1, all processes within the indicated scope receive the answer.

Output Parameters

<i>a</i>	TYPE array (<i>lda</i> , <i>n</i>). Contains the result if this process is selected to receive the answer, or intermediate results if the process is not selected to receive the result.
<i>ra</i>	INTEGER array (<i>rcflag</i> , <i>n</i>). If <i>rcflag</i> = -1, this array will not be referenced, and need not exist. Otherwise, it is an integer array (of size at least <i>rcflag</i> × <i>n</i>) indicating the row index of the process that provided the maximum. If the calling process is not selected to receive the result, this array will contain intermediate (useless) results.
<i>ca</i>	INTEGER array (<i>rcflag</i> , <i>n</i>). If <i>rcflag</i> = -1, this array will not be referenced, and need not exist. Otherwise, it is an integer array (of size at least <i>rcflag</i> × <i>n</i>) indicating the row index of the process that provided the maximum. If the calling process is not selected to receive the result, this array will contain intermediate (useless) results.

Description

This routine performs element-wise absolute value maximization, that is, each element of matrix *A* is compared with the corresponding element of the other process's matrices. Note that the value of *A* is returned, but the absolute value is used to determine the maximum (the 1-norm is used for complex numbers). Combines may be globally-blocking, so they must be programmed as if no process returns until all have called the routine.

?gamn2d

Performs element-wise absolute value minimization.

Syntax

```
call igamn2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest )
call sgamn2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest )
call dgamn2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest )
call cgamn2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest )
call zgamn2d( icontxt, scope, top, m, n, a, lda, ra, ca, rcflag, rdest, cdest )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>scope</i>	CHARACTER*1. Indicates what scope the combine should proceed on. Limited to ROW, COLUMN, or ALL.
<i>top</i>	CHARACTER*1. Communication pattern to use during the combine operation.

<i>m</i>	INTEGER. The number of matrix rows to be combined.
<i>n</i>	INTEGER. The number of matrix columns to be combined.
<i>a</i>	TYPE array (<i>lda</i> , <i>n</i>). Matrix to be compared with to produce the minimum.
<i>lda</i>	INTEGER. The leading dimension of the matrix <i>A</i> , that is, the distance between two successive elements in a matrix row.
<i>rcflag</i>	INTEGER. If <i>rcflag</i> = -1, the arrays <i>ra</i> and <i>ca</i> are not referenced and need not exist. Otherwise, <i>rcflag</i> indicates the leading dimension of these arrays, and so must be $\geq m$.
<i>rdest</i>	INTEGER. The process row coordinate of the process that should receive the result. If <i>rdest</i> or <i>cdest</i> = -1, all processes within the indicated scope receive the answer.
<i>cdest</i>	INTEGER. The process column coordinate of the process that should receive the result. If <i>rdest</i> or <i>cdest</i> = -1, all processes within the indicated scope receive the answer.

Output Parameters

<i>a</i>	TYPE array (<i>lda</i> , <i>n</i>). Contains the result if this process is selected to receive the answer, or intermediate results if the process is not selected to receive the result.
<i>ra</i>	INTEGER array (<i>rcflag</i> , <i>n</i>). If <i>rcflag</i> = -1, this array will not be referenced, and need not exist. Otherwise, it is an integer array (of size at least <i>rcflag</i> × <i>n</i>) indicating the row index of the process that provided the minimum. If the calling process is not selected to receive the result, this array will contain intermediate (useless) results.
<i>ca</i>	INTEGER array (<i>rcflag</i> , <i>n</i>). If <i>rcflag</i> = -1, this array will not be referenced, and need not exist. Otherwise, it is an integer array (of size at least <i>rcflag</i> × <i>n</i>) indicating the row index of the process that provided the minimum. If the calling process is not selected to receive the result, this array will contain intermediate (useless) results.

Description

This routine performs element-wise absolute value minimization, that is, each element of matrix *A* is compared with the corresponding element of the other process's matrices. Note that the value of *A* is returned, but the absolute value is used to determine the minimum (the 1-norm is used for complex numbers). Combines may be globally-blocking, so they must be programmed as if no process returns until all have called the routine.

?gsum2d

Performs element-wise summation.

Syntax

```
call igsum2d( icontxt, scope, top, m, n, a, lda, rdest, cdest )
call sgsum2d( icontxt, scope, top, m, n, a, lda, rdest, cdest )
call dgsum2d( icontxt, scope, top, m, n, a, lda, rdest, cdest )
call cgsum2d( icontxt, scope, top, m, n, a, lda, rdest, cdest )
call zgsum2d( icontxt, scope, top, m, n, a, lda, rdest, cdest )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>scope</i>	CHARACTER*1. Indicates what scope the combine should proceed on. Limited to ROW, COLUMN, or ALL.
<i>top</i>	CHARACTER*1. Communication pattern to use during the combine operation.
<i>m</i>	INTEGER. The number of matrix rows to be combined.
<i>n</i>	INTEGER. The number of matrix columns to be combined.
<i>a</i>	TYPE array (<i>lda</i> , <i>n</i>). Matrix to be added to produce the sum.
<i>lda</i>	INTEGER. The leading dimension of the matrix <i>A</i> , that is, the distance between two successive elements in a matrix row.
<i>rdest</i>	INTEGER. The process row coordinate of the process that should receive the result. If <i>rdest</i> or <i>cdest</i> = -1, all processes within the indicated scope receive the answer.
<i>cdest</i>	INTEGER. The process column coordinate of the process that should receive the result. If <i>rdest</i> or <i>cdest</i> = -1, all processes within the indicated scope receive the answer.

Output Parameters

<i>a</i>	TYPE array (<i>lda</i> , <i>n</i>). Contains the result if this process is selected to receive the answer, or intermediate results if the process is not selected to receive the result.

Description

This routine performs element-wise summation, that is, each element of matrix *A* is summed with the corresponding element of the other process's matrices. Combines may be globally-blocking, so they must be programmed as if no process returns until all have called the routine.

BLACS Point To Point Communication

This section describes BLACS routines for point to point communication.

Point to point communication requires two complementary operations. The *send* operation produces a message that is then consumed by the *receive* operation. These operations have various resources associated with them. The main such resource is the buffer that holds the data to be sent or serves as the area where the incoming data is to be received. The level of *blocking* indicates what correlation the return from a send/receive operation has with the availability of these resources and with the status of message.

Non-blocking

The return from the *send* or *receive* operations does not imply that the resources may be reused, that the message has been sent/received or that the complementary operation has been called. Return means only that the send/receive has been started, and will be completed at some later date. Polling is required to determine when the operation has finished.

In non-blocking message passing, the concept of *communication/computation overlap* (abbreviated C/C overlap) is important. If a system possesses C/C overlap, independent computation can occur at the same time as communication. That means a nonblocking operation can be posted, and unrelated work can be done while the message is sent/received in parallel. If C/C overlap is not present, after returning from the routine call, computation will be interrupted at some later date when the message is actually sent or received.

Locally-blocking

Return from the *send* or *receive* operations indicates that the resources may be reused. However, since this only depends on local information, it is unknown whether the complementary operation has been called. There are no locally-blocking receives: the send must be completed before the receive buffer is available for re-use.

If a receive has not been posted at the time a locally-blocking send is issued, buffering will be required to avoid losing the message. Buffering can be done on the sending process, the receiving process, or not done at all, losing the message.

Globally-blocking

Return from a globally-blocking procedure indicates that the operation resources may be reused, and that complement of the operation has at least been posted. Since the receive has been posted, there is no buffering required for globally-blocking sends: the message is always sent directly into the user's receive buffer.

Almost all processors support non-blocking communication, as well as some other level of blocking sends. What level of blocking the send possesses varies between platforms. For instance, the Intel® processors support locally-blocking sends, with buffering done on the receiving process. This is a very important distinction, because codes written assuming locally-blocking sends will hang on platforms with globally-blocking sends. Below is a simple example of how this can occur:

```
IAM = MY_PROCESS_ID()
IF (IAM.EQ. 0) THEN
  SEND TO PROCESS 1
  RECV FROM PROCESS 1
ELSE IF (IAM.EQ. 1) THEN
```

```

SEND TO PROCESS 0
RECV FROM PROCESS 0
END IF

```

If the send is globally-blocking, process 0 enters the send, and waits for process 1 to start its receive before continuing. In the meantime, process 1 starts to send to 0, and waits for 0 to receive before continuing. Both processes are now waiting on each other, and the program will never continue.

The solution for this case is obvious. One of the processes simply reverses the order of its communication calls and the hang is avoided. However, when the communication is not just between two processes, but rather involves a hierarchy of processes, determining how to avoid this kind of difficulty can become problematic.

For this reason, it was decided the BLACS would support locally-blocking sends. On systems natively supporting globally-blocking sends, non-blocking sends coupled with buffering is used to simulate locally-blocking sends. The BLACS support globally-blocking receives.

In addition, the BLACS specify that point to point messages between two given processes will be strictly ordered. If process 0 sends three messages (label them *A*, *B*, and *C*) to process 1, process 1 must receive *A* before it can receive *B*, and message *C* can be received only after both *A* and *B*. The main reason for this restriction is that it allows for the computation of message identifiers.

Note, however, that messages from different processes are not ordered. If processes 0, . . . , 3 send messages *A*, . . . , *D* to process 4, process 4 may receive these messages in any order that is convenient.

Convention

The convention used in the communication routine names follows the template `?xxyy2d`, where the letter in the `?` position indicates the data type being sent, `xx` is replaced to indicate the shape of the matrix, and the `yy` positions are used to indicate the type of communication to perform:

i	integer
s	single precision real
d	double precision real
c	single precision complex
z	double precision complex
ge	The data to be communicated is stored in a general rectangular matrix.
tr	The data to be communicated is stored in a trapezoidal matrix.
sd	Send. One process sends to another.
rv	Receive. One process receives from another.

BLACS Point To Point Communication

Routine name	Operation performed
gesd2d	Take the indicated matrix and send it to the destination process.
trsd2d	
gerv2d	Receive a message from the process into the matrix.
trrv2d	

As a simple example, the pseudo code given above is rewritten below in terms of the BLACS. It is further specified that the data being exchanged is the double precision vector X , which is 5 elements long.

```
CALL GRIDINFO(NPROW, NPCOL, MYPROW, MYPCOL)

IF (MYPROW.EQ.0 .AND. MYPCOL.EQ.0) THEN
  CALL DGESD2D(5, 1, X, 5, 1, 0)
  CALL DGERV2D(5, 1, X, 5, 1, 0)
ELSE IF (MYPROW.EQ.1 .AND. MYPCOL.EQ.0) THEN
  CALL DGESD2D(5, 1, X, 5, 0, 0)
  CALL DGERV2D(5, 1, X, 5, 0, 0)
END IF
```

?gesd2d

Takes a general rectangular matrix and sends it to the destination process.

Syntax

```
call igesd2d( icontxt, m, n, a, lda, rdest, cdest )
call sgesd2d( icontxt, m, n, a, lda, rdest, cdest )
call dgesd2d( icontxt, m, n, a, lda, rdest, cdest )
call cgesd2d( icontxt, m, n, a, lda, rdest, cdest )
call zgesd2d( icontxt, m, n, a, lda, rdest, cdest )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>m, n, a, lda</i>	Describe the matrix to be sent. See Matrix Shapes for details.
<i>rdest</i>	INTEGER. The process row coordinate of the process to send the message to.
<i>cdest</i>	INTEGER. The process column coordinate of the process to send the message to.

Description

This routine takes the indicated general rectangular matrix and sends it to the destination process located at {RDEST, CDEST} in the process grid. Return from the routine indicates that the buffer (the matrix A) may be reused. The routine is locally-blocking, that is, it will return even if the corresponding receive is not posted.

See Also

[Examples of BLACS Routines Usage](#)

?trsd2d

Takes a trapezoidal matrix and sends it to the destination process.

Syntax

```
call itrdsd2d( icontxt, uplo, diag, m, n, a, lda, rdest, cdest )
call strsd2d( icontxt, uplo, diag, m, n, a, lda, rdest, cdest )
```

```
call dtrsd2d( icontxt, uplo, diag, m, n, a, lda, rdest, cdest )
call ctrsd2d( icontxt, uplo, diag, m, n, a, lda, rdest, cdest )
call ztrsd2d( icontxt, uplo, diag, m, n, a, lda, rdest, cdest )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>uplo, diag, m,</i> <i>n, a, lda</i>	Describe the matrix to be sent. See Matrix Shapes for details.
<i>rdest</i>	INTEGER. The process row coordinate of the process to send the message to.
<i>cdest</i>	INTEGER. The process column coordinate of the process to send the message to.

Description

This routine takes the indicated trapezoidal matrix and sends it to the destination process located at {RDEST, CDEST} in the process grid. Return from the routine indicates that the buffer (the matrix A) may be reused. The routine is locally-blocking, that is, it will return even if the corresponding receive is not posted.

?gerv2d

Receives a message from the process into the general rectangular matrix.

Syntax

```
call igerv2d( icontxt, m, n, a, lda, rsrc, csrc )
call sgerv2d( icontxt, m, n, a, lda, rsrc, csrc )
call dgerv2d( icontxt, m, n, a, lda, rsrc, csrc )
call cgerv2d( icontxt, m, n, a, lda, rsrc, csrc )
call zgerv2d( icontxt, m, n, a, lda, rsrc, csrc )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>m, n, lda</i>	Describe the matrix to be sent. See Matrix Shapes for details.
<i>rsrc</i>	INTEGER. The process row coordinate of the source of the message.
<i>csrc</i>	INTEGER. The process column coordinate of the source of the message.

Output Parameters

<i>a</i>	An array of dimension (lda, n) to receive the incoming message into.

Description

This routine receives a message from process {RSRC, CSRC} into the general rectangular matrix A. This routine is globally-blocking, that is, return from the routine indicates that the message has been received into A.

See Also

[Examples of BLACS Routines Usage](#)

?trrv2d

Receives a message from the process into the trapezoidal matrix.

Syntax

```
call itrrv2d( icontxt, uplo, diag, m, n, a, lda, rsrc, csrc )
call strrv2d( icontxt, uplo, diag, m, n, a, lda, rsrc, csrc )
call dtrrv2d( icontxt, uplo, diag, m, n, a, lda, rsrc, csrc )
call ctrrv2d( icontxt, uplo, diag, m, n, a, lda, rsrc, csrc )
call ztrrv2d( icontxt, uplo, diag, m, n, a, lda, rsrc, csrc )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>uplo, diag, m, n, lda</i>	Describe the matrix to be sent. See Matrix Shapes for details.
<i>rsrc</i>	INTEGER. The process row coordinate of the source of the message.
<i>csrc</i>	INTEGER. The process column coordinate of the source of the message.

Output Parameters

<i>a</i>	An array of dimension (lda, n) to receive the incoming message into.

Description

This routine receives a message from process {RSRC, CSRC} into the trapezoidal matrix A. This routine is globally-blocking, that is, return from the routine indicates that the message has been received into A.

BLACS Broadcast Routines

This section describes BLACS broadcast routines.

A broadcast sends data possessed by one process to all processes within a scope. Broadcast, much like point to point communication, has two complementary operations. The process that owns the data to be broadcast issues a *broadcast/send*. All processes within the same scope must then issue the complementary *broadcast/receive*.

The BLACS define that both broadcast/send and broadcast/receive are *globally-blocking*. Broadcasts/receives cannot be locally-blocking since they must post a receive. Note that receives cannot be locally-blocking. When a given process can leave, a broadcast/receive operation is topology dependent, so, to avoid a hang as topology is varied, the broadcast/receive must be treated as if no process can leave until all processes have called the operation.

Broadcast/sends could be defined to be *locally-blocking*. Since no information is being received, as long as locally-blocking point to point sends are used, the broadcast/send will be locally blocking. However, defining one process within a scope to be locally-blocking while all other processes are globally-blocking adds little to the programmability of the code. On the other hand, leaving the option open to have globally-blocking broadcast/sends may allow for optimization on some platforms.

The fact that broadcasts are defined as globally-blocking has several important implications. The first is that scoped operations (broadcasts or combines) must be strictly ordered, that is, all processes within a scope must agree on the order of calls to separate scoped operations. This constraint falls in line with that already in place for the computation of message IDs, and is present in point to point communication as well.

A less obvious result is that scoped operations with `SCOPE = 'ALL'` must be ordered with respect to any other scoped operation. This means that if there are two broadcasts to be done, one along a column, and one involving the entire process grid, all processes within the process column issuing the column broadcast must agree on which broadcast will be performed first.

The convention used in the communication routine names follows the template `?xxyy2d`, where the letter in the `?` position indicates the data type being sent, `xx` is replaced to indicate the shape of the matrix, and the `yy` positions are used to indicate the type of communication to perform:

i	integer
s	single precision real
d	double precision real
c	single precision complex
z	double precision complex
ge	The data to be communicated is stored in a general rectangular matrix.
tr	The data to be communicated is stored in a trapezoidal matrix.
bs	Broadcast/send. A process begins the broadcast of data within a scope.
br	Broadcast/receive A process receives and participates in the broadcast of data within a scope.

BLACS Broadcast Routines

Routine name	Operation performed
gebs2d	Start a broadcast along a scope.
trbs2d	
gebr2d	Receive and participate in a broadcast along a scope.
trbr2d

Notice revision #20110804

?gebs2d

Starts a broadcast along a scope for a general rectangular matrix.

Syntax

```
call igesb2d( icontxt, scope, top, m, n, a, lda )
call sgesb2d( icontxt, scope, top, m, n, a, lda )
call dgesb2d( icontxt, scope, top, m, n, a, lda )
call cgesb2d( icontxt, scope, top, m, n, a, lda )
call zgesb2d( icontxt, scope, top, m, n, a, lda )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>scope</i>	CHARACTER*1. Indicates what scope the broadcast should proceed on. Limited to 'Row', 'Column', or 'All'.
<i>top</i>	CHARACTER*1. Indicates the communication pattern to use for the broadcast.
<i>m, n, a, lda</i>	Describe the matrix to be sent. See Matrix Shapes for details.

Description

This routine starts a broadcast along a scope. All other processes within the scope must call broadcast/receive for the broadcast to proceed. At the end of a broadcast, all processes within the scope will possess the data in the general rectangular matrix *A*.

Broadcasts may be globally-blocking. This means no process is guaranteed to return from a broadcast until all processes in the scope have called the appropriate routine (broadcast/send or broadcast/receive).

[Examples of BLACS Routines Usage](#)

?trbs2d

Starts a broadcast along a scope for a trapezoidal matrix.

Syntax

```
call itrbs2d( icontxt, scope, top, uplo, diag, m, n, a, lda )
call strbs2d( icontxt, scope, top, uplo, diag, m, n, a, lda )
call dtrbs2d( icontxt, scope, top, uplo, diag, m, n, a, lda )
call ctrbs2d( icontxt, scope, top, uplo, diag, m, n, a, lda )
```

```
call ztrbs2d( icontxt, scope, top, uplo, diag, m, n, a, lda )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>scope</i>	CHARACTER*1. Indicates what scope the broadcast should proceed on. Limited to 'Row', 'Column', or 'All'.
<i>top</i>	CHARACTER*1. Indicates the communication pattern to use for the broadcast.
<i>uplo, diag, m, n, a, lda</i>	Describe the matrix to be sent. See Matrix Shapes for details.

Description

This routine starts a broadcast along a scope. All other processes within the scope must call broadcast/receive for the broadcast to proceed. At the end of a broadcast, all processes within the scope will possess the data in the trapezoidal matrix *A*.

Broadcasts may be globally-blocking. This means no process is guaranteed to return from a broadcast until all processes in the scope have called the appropriate routine (broadcast/send or broadcast/receive).

?gebr2d

Receives and participates in a broadcast along a scope for a general rectangular matrix.

Syntax

```
call igebr2d( icontxt, scope, top, m, n, a, lda, rsrc, csrc )
call sgebr2d( icontxt, scope, top, m, n, a, lda, rsrc, csrc )
call dgebr2d( icontxt, scope, top, m, n, a, lda, rsrc, csrc )
call cgebr2d( icontxt, scope, top, m, n, a, lda, rsrc, csrc )
call zgebr2d( icontxt, scope, top, m, n, a, lda, rsrc, csrc )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>scope</i>	CHARACTER*1. Indicates what scope the broadcast should proceed on. Limited to 'Row', 'Column', or 'All'.
<i>top</i>	CHARACTER*1. Indicates the communication pattern to use for the broadcast.
<i>m, n, lda</i>	Describe the matrix to be sent. See Matrix Shapes for details.
<i>rsrc</i>	INTEGER. The process row coordinate of the process that called broadcast/send.
<i>csrc</i>	INTEGER. The process column coordinate of the process that called broadcast/send.

Output Parameters

a An array of dimension (lda, n) to receive the incoming message into.

Description

This routine receives and participates in a broadcast along a scope. At the end of a broadcast, all processes within the scope will possess the data in the general rectangular matrix *A*. Broadcasts may be globally-blocking. This means no process is guaranteed to return from a broadcast until all processes in the scope have called the appropriate routine (broadcast/send or broadcast/receive).

See Also

[Examples of BLACS Routines Usage](#)

?trbr2d

Receives and participates in a broadcast along a scope for a trapezoidal matrix.

Syntax

```
call itrbr2d( icontxt, scope, top, uplo, diag, m, n, a, lda, rsrc, csrc )
call strbr2d( icontxt, scope, top, uplo, diag, m, n, a, lda, rsrc, csrc )
call dtrbr2d( icontxt, scope, top, uplo, diag, m, n, a, lda, rsrc, csrc )
call ctrbr2d( icontxt, scope, top, uplo, diag, m, n, a, lda, rsrc, csrc )
call ztrbr2d( icontxt, scope, top, uplo, diag, m, n, a, lda, rsrc, csrc )
```

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle that indicates the context.
<i>scope</i>	CHARACTER*1. Indicates what scope the broadcast should proceed on. Limited to 'Row', 'Column', or 'All'.
<i>top</i>	CHARACTER*1. Indicates the communication pattern to use for the broadcast.
<i>uplo, diag, m, n, lda</i>	Describe the matrix to be sent. See Matrix Shapes for details.
<i>rsrc</i>	INTEGER. The process row coordinate of the process that called broadcast/send.
<i>csrc</i>	INTEGER. The process column coordinate of the process that called broadcast/send.

Output Parameters

a An array of dimension (lda, n) to receive the incoming message into.

Description

This routine receives and participates in a broadcast along a scope. At the end of a broadcast, all processes within the scope will possess the data in the trapezoidal matrix *A*. Broadcasts may be globally-blocking. This means no process is guaranteed to return from a broadcast until all processes in the scope have called the appropriate routine (broadcast/send or broadcast/receive).

The support routines perform distinct tasks that can be used for:

Destruction

Information Purposes

Miscellaneous Tasks.

This section describes BLACS routines that deal with grid/context creation, and processing before the grid/context has been defined.

Routine name	Operation performed
blacs_pinfo	Returns the number of processes available for use.
blacs_setup	Allocates virtual machine and spawns processes.
blacs_get	Gets values that BLACS use for internal defaults.
blacs_set	Sets values that BLACS use for internal defaults.
blacs_gridinit	Assigns available processes into BLACS process grid.
blacs_gridmap	Maps available processes into BLACS process grid.

Returns the number of processes available for use.

```
call blacs pinfo( mypnum, nprocs )
```

<i>mypnun</i>	INTEGER. An integer between 0 and (<i>nprocs</i> - 1) that uniquely identifies each process.
<i>nprocs</i>	INTEGER. The number of processes available for BLACS use.

This routine is used when some initial system information is required before the BLACS are set up. On all platforms except PVM, *nprocs* is the actual number of processes available for use, that is, *nprocs* * *npcols* <= *nprocs*. In PVM, the virtual machine may not have been set up before this call, and therefore no parallel machine exists. In this case, *nprocs* is returned as less than one. If a process has been spawned via the keyboard, it receives *mypnum* of 0, and all other processes get *mypnum* of -1. As a result, the user can distinguish between processes. Only after the virtual machine has been set up via a call to `BLACS_SETUP`, this routine returns the correct values for *mypnum* and *nprocs*.

Examples of BLACS Routines Usage

blacs_setup

Allocates virtual machine and spawns processes.

Syntax

```
call blacs_setup( mypnum, nprocs )
```

Input Parameters

nprocs INTEGER. On the process spawned from the keyboard rather than from `pvmspawn`, this parameter indicates the number of processes to create when building the virtual machine.

Output Parameters

mypnum INTEGER. An integer between 0 and (*nprocs* - 1) that uniquely identifies each process.

nprocs INTEGER. For all processes other than spawned from the keyboard, this parameter means the number of processes available for BLACS use.

Description

This routine only accomplishes meaningful work in the PVM BLACS. On all other platforms, it is functionally equivalent to `blacs_pinfo`. The BLACS assume a static system, that is, the given number of processes does not change. PVM supplies a dynamic system, allowing processes to be added to the system on the fly.

`blacs_setup` is used to allocate the virtual machine and spawn off processes. It reads in a file called `blacs_setup.dat`, in which the first line must be the name of your executable. The second line is optional, but if it exists, it should be a PVM spawn flag. Legal values at this time are 0 (`PvmTaskDefault`), 4 (`PvmTaskDebug`), 8 (`PvmTaskTrace`), and 12 (`PvmTaskDebug + PvmTaskTrace`). The primary reason for this line is to allow the user to easily turn on and off PVM debugging. Additional lines, if any, specify what machines should be added to the current configuration before spawning *nprocs*-1 processes to the machines in a round robin fashion.

nprocs is input on the process which has no PVM parent (that is, *mypnum*=0), and both parameters are output for all processes. So, on PVM systems, the call to `blacs_pinfo` informs you that the virtual machine has not been set up, and a call to `blacs_setup` then sets up the machine and returns the real values for *mypnum* and *nprocs*.

Note that if the file `blacs_setup.dat` does not exist, the BLACS prompt the user for the executable name, and processes are spawned to the current PVM configuration.

[Examples of BLACS Routines Usage](#)

blacs_get

Gets values that BLACS use for internal defaults.

Syntax

```
call blacs_get( icontxt, what, val )
```

Input Parameters

icontxt INTEGER. On values of *what* that are tied to a particular context, this parameter is the integer handle indicating the context. Otherwise, ignored.

what

INTEGER. Indicates what BLACS internal(s) should be returned in *val*.
Present options are:

- *what* = 0 : Handle indicating default system context.
- *what* = 1 : The BLACS message ID range.
- *what* = 2 : The BLACS debug level the library was compiled with.
- *what* = 10 : Handle indicating the system context used to define the BLACS context whose handle is *icontxt*.
- *what* = 11 : Number of rings multiring broadcast topology is presently using.
- *what* = 12 : Number of branches general tree broadcast topology is presently using.
- *what* = 13 : Number of rings multiring combine topology is presently using.
- *what* = 14 : Number of branches general tree combine topology is presently using.
- *what* = 15 : Whether topologies are forced to be repeatable or not. A non-zero return value indicates that topologies are being forced to be repeatable. See [Repeatability and Coherence](#) for more information about repeatability.
- *what* = 16 : Whether topologies are forced to be heterogenous coherent or not. A non-zero return value indicates that topologies are being forced to be heterogenous coherent. See [Repeatability and Coherence](#) for more information about coherence.

Output Parameters

val

INTEGER. The value of the BLACS internal.

Description

This routine gets the values that the BLACS are using for internal defaults. Some values are tied to a BLACS context, and some are more general. The most common use is in retrieving a default system context for input into [blacs_gridinit](#) or [blacs_gridmap](#).

Some systems, such as MPI*, supply their own version of context. For those users who mix system code with BLACS code, a BLACS context should be formed in reference to a system context. Thus, the grid creation routines take a system context as input. If you wish to have strictly portable code, you may use [blacs_get](#) to retrieve a default system context that will include all available processes. This value is not tied to a BLACS context, so the parameter *icontxt* is unused.

[blacs_get](#) returns information on three quantities that are tied to an individual BLACS context, which is passed in as *icontxt*. The information that may be retrieved is:

- The handle of the system context upon which this BLACS context was defined
- The number of rings for TOP = 'M' (multiring broadcast/combine)
- The number of branches for TOP = 'T' (general tree broadcast/general tree gather).
- Whether topologies are being forced to be repeatable or heterogenous coherent.

See Also

[Examples of BLACS Routines Usage](#)

[blacs_set](#)

Sets values that BLACS use for internal defaults.

Syntax

```
call blacs_set( ictxt, what, val )
```

Input Parameters

<i>ictxt</i>	INTEGER. For values of <i>what</i> that are tied to a particular context, this parameter is the integer handle indicating the context. Otherwise, ignored.
<i>what</i>	INTEGER. Indicates what BLACS internal(s) should be set. Present values are: • 1 = Set the BLACS message ID range • 11 = Number of rings for multiring broadcast topology to use • 12 = Number of branches for general tree broadcast topology to use • 13 = Number of rings for multiring combine topology to use • 14 = Number of branches for general tree combine topology to use • 15 = Force topologies to be repeatable or not • 16 = Force topologies to be heterogenous coherent or not
<i>val</i>	INTEGER. Array of dimension (*). Indicates the value(s) the internals should be set to. The specific meanings depend on <i>what</i> values, as discussed in Description below.

Description

This routine sets the BLACS internal defaults depending on *what* values:

<i>what</i> = 1	Setting the BLACS message ID range. If you wish to mix the BLACS with other message-passing packages, restrict the BLACS to a certain message ID range not to be used by the non-BLACS routines. The message ID range must be set before the first call to blacs_gridinit or blacs_gridmap. Subsequent calls will have no effect. Because the message ID range is not tied to a particular context, the parameter <i>ictxt</i> is ignored, and <i>val</i> is defined as: VAL (input) INTEGER array of dimension (2) VAL(1) : The smallest message ID (also called message type or message tag) the BLACS should use. VAL(2) : The largest message ID (also called message type or message tag) the BLACS should use.
<i>what</i> = 11	Set number of rings for TOP = 'M' (multiring broadcast). This quantity is tied to a context, so <i>ictxt</i> is used, and <i>val</i> is defined as: VAL (input) INTEGER array of dimension (1) VAL(1) : The number of rings for multiring topology to use.
<i>what</i> = 12	Set number of branches for TOP = 'T' (general tree broadcast). This quantity is tied to a context, so <i>ictxt</i> is used, and <i>val</i> is defined as: VAL (input) INTEGER array of dimension (1) VAL(1) : The number of branches for general tree topology to use.

<i>what</i> = 13	Set number of rings for TOP = 'M' (multiring combine). This quantity is tied to a context, so <i>icontxt</i> is used, and <i>val</i> is defined as: VAL (input) INTEGER array of dimension (1) VAL(1) : The number of rings for multiring topology to use.
<i>what</i> = 14	Set number of branches for TOP = 'T' (general tree gather). This quantity is tied to a context, so <i>icontxt</i> is used, and <i>val</i> is defined as: VAL (input) INTEGER array of dimension (1) VAL(1) : The number of branches for general tree topology to use.
<i>what</i> = 15	Force topologies to be repeatable or not (see Repeatability and Coherence for more information about repeatability). VAL (input) INTEGER array of dimension (1) VAL(1) = 0 (default) Topologies are not required to be repeatable. VAL(1) ≠ 0 All used topologies are required to be repeatable, which might degrade performance.
<i>what</i> = 16	Force topologies to be heterogenous coherent or not (see Repeatability and Coherence for more information about coherence). VAL (input) INTEGER array of dimension (1) VAL(1) = 0 (default) Topologies are not required to be heterogenous coherent. VAL(1) ≠ 0 All used topologies are required to be heterogenous coherent, which might degrade performance.

blacs_gridinit

Assigns available processes into BLACS process grid.

Syntax

call blacs_gridinit(*icontxt*, *layout*, *nprow*, *npcol*)

Input Parameters

<i>icontxt</i>	INTEGER. Integer handle indicating the system context to be used in creating the BLACS context. Call <i>blacs_get</i> to obtain a default system context.
<i>layout</i>	CHARACTER*1. Indicates how to map processes to BLACS grid. Options are: • 'R' : Use row-major natural ordering • 'C' : Use column-major natural ordering • ELSE : Use row-major natural ordering
<i>nprow</i>	INTEGER. Indicates how many process rows the process grid should contain.

npcol INTEGER. Indicates how many process columns the process grid should contain.

Output Parameters

icontxt INTEGER. Integer handle to the created BLACS context.

Description

All BLACS codes must call this routine, or its sister routine `blacs_gridmap`. These routines take the available processes, and assign, or map, them into a BLACS process grid. In other words, they establish how the BLACS coordinate system maps into the native machine process numbering system. Each BLACS grid is contained in a context, so that it does not interfere with distributed operations that occur within other grids/contexts. These grid creation routines may be called repeatedly to define additional contexts/grids.

The creation of a grid requires input from all processes that are defined to be in this grid. Processes belonging to more than one grid have to agree on which grid formation will be serviced first, much like the globally blocking sum or broadcast.

These grid creation routines set up various internals for the BLACS, and one of them must be called before any calls are made to the non-initialization BLACS.

Note that these routines map already existing processes to a grid: the processes are not created dynamically. On most parallel machines, the processes are "created" when you run your executable. When using the PVM BLACS, if the virtual machine has not been set up yet, the routine `blacs_setup` should be used to create the virtual machine.

This routine creates a simple `nprow` x `npcol` process grid. This process grid uses the first `nprow` * `npcol` processes, and assigns them to the grid in a row- or column-major natural ordering. If these process-to-grid mappings are unacceptable, call `blacs_gridmap`.

[blacs_get](#)

[blacs_gridmap](#)

[blacs_setup](#)

blacs_gridmap

Maps available processes into BLACS process grid.

Syntax

```
call blacs_gridmap( icontxt, usermap, ldumap, nprow, npcol )
```

Input Parameters

icontxt INTEGER. Integer handle indicating the system context to be used in creating the BLACS context. Call `blacs_get` to obtain a default system context.

usermap INTEGER. Array, dimension (*ldumap*, *npcol*), indicating the process-to-grid mapping.

ldumap INTEGER. Leading dimension of the 2D array *usermap*. *ldumap* ≥ *nprow*.

nprow INTEGER. Indicates how many process rows the process grid should contain.

npcol INTEGER. Indicates how many process columns the process grid should contain.

Output Parameters

icontxt INTEGER. Integer handle to the created BLACS context.

Description

All BLACS codes must call this routine, or its sister routine `blacs_gridinit`. These routines take the available processes, and assign, or map, them into a BLACS process grid. In other words, they establish how the BLACS coordinate system maps into the native machine process numbering system. Each BLACS grid is contained in a context, so that it does not interfere with distributed operations that occur within other grids/contexts. These grid creation routines may be called repeatedly to define additional contexts/grids.

The creation of a grid requires input from all processes that are defined to be in this grid. Processes belonging to more than one grid have to agree on which grid formation will be serviced first, much like the globally blocking sum or broadcast.

These grid creation routines set up various internals for the BLACS, and one of them must be called before any calls are made to the non-initialization BLACS.

Note that these routines map already existing processes to a grid: the processes are not created dynamically. On most parallel machines, the processes are actual processors (hardware), and they are "created" when you run your executable. When using the PVM BLACS, if the virtual machine has not been set up yet, the routine `blacs_setup` should be used to create the virtual machine.

This routine allows the user to map processes to the process grid in an arbitrary manner. `usermap(i,j)` holds the process number of the process to be placed in $\{i, j\}$ of the process grid. On most distributed systems, this process number is a machine defined number between $0 \dots nprow-1$. For PVM, these node numbers are the PVM TIDS (Task IDs). The `blacs_gridmap` routine is intended for an experienced user. The `blacs_gridinit` routine is much simpler. `blacs_gridinit` simply performs a `gridmap` where the first $nprow * npcold$ processes are mapped into the current grid in a row-major natural ordering. If you are an experienced user, `blacs_gridmap` allows you to take advantage of your system's actual layout. That is, you can map nodes that are physically connected to be neighbors in the BLACS grid, etc. The `blacs_gridmap` routine also opens the way for *multigridding*: you can separate your nodes into arbitrary grids, join them together at some later date, and then re-split them into new grids. `blacs_gridmap` also provides the ability to make arbitrary grids or subgrids (for example, a "nearest neighbor" grid), which can greatly facilitate operations among processes that do not fall on a row or column of the main process grid.

[blacs_setup](#)

Destruction Routines

This section describes BLACS routines that destroy grids, abort processes, and free resources.

BLACS Destruction Routines

Routine name	Operation performed
blacs_freebuff	Frees BLACS buffer.
blacs_gridexit	Frees a BLACS context.

Routine name	Operation performed
blacs_abort	Aborts all processes.
blacs_exit	Frees all BLACS contexts and releases all allocated memory.

[blacs_freebuff](#)

Frees BLACS buffer.

Syntax

```
call blacs_freebuff( ictxt, wait )
```

Input Parameters

<i>ictxt</i>	INTEGER. Integer handle that indicates the BLACS context.
<i>wait</i>	INTEGER. Parameter indicating whether to wait for non-blocking operations or not. If equals 0, the operations should not be waited for; free only unused buffers. Otherwise, wait in order to free all buffers.

Description

This routine releases the BLACS buffer.

The BLACS have at least one internal buffer that is used for packing messages. The number of internal buffers depends on what platform you are running the BLACS on. On systems where memory is tight, keeping this buffer or buffers may become expensive. Call `freebuff` to release the buffer. However, the next call of a communication routine that requires packing reallocates the buffer.

The *wait* parameter determines whether the BLACS should wait for any non-blocking operations to be completed or not. If *wait* = 0, the BLACS free any buffers that can be freed without waiting. If *wait* is not 0, the BLACS free all internal buffers, even if non-blocking operations must be completed first.

[blacs_gridexit](#)

Frees a BLACS context.

Syntax

```
call blacs_gridexit( ictxt )
```

Input Parameters

<i>ictxt</i>	INTEGER. Integer handle that indicates the BLACS context to be freed.

Description

This routine frees a BLACS context.

Release the resources when contexts are no longer needed. After freeing a context, the context no longer exists, and its handle may be re-used if new contexts are defined.

[blacs_abort](#)

Aborts all processes.

Syntax

```
call blacs_abort( ictxt, errornum )
```

Input Parameters

<i>ictxt</i>	INTEGER. Integer handle that indicates the BLACS context to be aborted.
<i>errornum</i>	INTEGER. User-defined integer error number.

Description

This routine aborts all the BLACS processes, not only those confined to a particular context.

Use `blacs_abort` to abort all the processes in case of a serious error. Note that both parameters are input, but the routine uses them only in printing out the error message. The context handle passed in is not required to be a valid context handle.

`blacs_exit`

Frees all BLACS contexts and releases all allocated memory.

Syntax

```
call blacs_exit( continue )
```

Input Parameters

<i>continue</i>	INTEGER. Flag indicating whether message passing continues after the BLACS are done. If <i>continue</i> is non-zero, the user is assumed to continue using the machine after completing the BLACS. Otherwise, no message passing is assumed after calling this routine.

Description

This routine frees all BLACS contexts and releases all allocated memory.

This routine should be called when a process has finished all use of the BLACS. The *continue* parameter indicates whether the user will be using the underlying communication platform after the BLACS are finished. This information is most important for the PVM BLACS. If *continue* is set to 0, then `pvm_exit` is called; otherwise, it is not called. Setting *continue* not equal to 0 indicates that explicit PVM `send/recvs` will be called after the BLACS routines are used. Make sure your code calls `pvm_exit`. PVM users should either call `blacs_exit` or explicitly call `pvm_exit` to avoid PVM problems.

Informational Routines

This section describes BLACS routines that return information involving the process grid.

BLACS Informational Routines

Routine name	Operation performed
<code>blacs_gridinfo</code>	Returns information on the current grid.
<code>blacs_pnum</code>	Returns the system process number of the process in the process grid.
<code>blacs_pcoord</code>	Returns the row and column coordinates in the process grid.

blacs_gridinfo

Returns information on the current grid.

Syntax

```
call blacs_gridinfo( ictxt, nprow, npcol, myprow, mypcol )
```

Input Parameters

<i>ictxt</i>	INTEGER. Integer handle that indicates the context.

Output Parameters

<i>nprow</i>	INTEGER. Number of process rows in the current process grid.
<i>npcol</i>	INTEGER. Number of process columns in the current process grid.
<i>myprow</i>	INTEGER. Row coordinate of the calling process in the process grid.
<i>mypcol</i>	INTEGER. Column coordinate of the calling process in the process grid.

Description

This routine returns information on the current grid. If the context handle does not point at a valid context, all quantities are returned as -1.

See Also

[Examples of BLACS Routines Usage](#)

blacs_pnum

Returns the system process number of the process in the process grid.

Syntax

```
call blacs_pnum( ictxt, prow, pcol )
```

Input Parameters

<i>ictxt</i>	INTEGER. Integer handle that indicates the context.
<i>prow</i>	INTEGER. Row coordinate of the process the system process number of which is to be determined.
<i>pcol</i>	INTEGER. Column coordinate of the process the system process number of which is to be determined.

Description

This function returns the system process number of the process at {PROW, PCOL} in the process grid.

See Also

[Examples of BLACS Routines Usage](#)

blacs_pcoord

Returns the row and column coordinates in the process grid.

Syntax

```
call blacs_pcoord( ictxt, pnum, prow, pcol )
```

Input Parameters

ictxt INTEGER. Integer handle that indicates the context.

pnum INTEGER. Process number the coordinates of which are to be determined. This parameter stand for the process number of the underlying machine, that is, it is a `tid` for PVM.

Output Parameters

prow INTEGER. Row coordinates of the *pnum* process in the BLACS grid.

pcol INTEGER. Column coordinates of the *pnum* process in the BLACS grid.

Description

Given the system process number, this function returns the row and column coordinates in the BLACS process grid.

Examples of BLACS Routines Usage

Miscellaneous Routines

This section describes `blacs_barrier` routine.

BLACS Informational Routines

Routine name	Operation performed
<code>blacs_barrier</code>	Holds up execution of all processes within the indicated scope until they have all called the routine.

`blacs_barrier`

Holds up execution of all processes within the indicated scope.

Syntax

```
call blacs_barrier( ictxt, scope )
```

Input Parameters

ictxt INTEGER. Integer handle that indicates the context.

scope CHARACTER*1. Parameter that indicates whether a process row (*scope*='R'), column ('C'), or entire grid ('A') will participate in the barrier.

Description

This routine holds up execution of all processes within the indicated scope until they have all called the routine.

Examples of BLACS Routines Usage

Data Fitting Functions

Data Fitting functions in Intel® MKL provide spline-based interpolation capabilities that you can use to approximate functions, function derivatives or integrals, and perform cell search operations.

The Data Fitting component is task based. The task is a data structure or descriptor that holds the parameters related to a specific Data Fitting operation. You can modify the task parameters using the task editing functionality of the library.

For definition of the implemented operations, see [Mathematical Conventions](#).

Data Fitting routines use the following workflow to process a task:

1. Create a task or multiple tasks.
2. Modify the task parameters.
3. Perform a Data Fitting computation.
4. Destroy the task or tasks.

All Data Fitting functions fall into the following categories:

[Task Creation and Initialization Routines](#) - routines that create a new Data Fitting task descriptor and initialize the most common parameters, such as partition of the interpolation interval, values of the vector-valued function, and the parameters describing their structure.

[Task Configuration Routines](#) - routines that set, modify, or query parameters in an existing Data Fitting task.

[Computational Routines](#) - routines that perform Data Fitting computations, such as construction of a spline, interpolation, computation of derivatives and integrals, and search.

[Task Destructors](#) - routines that delete Data Fitting task descriptors and deallocate resources.

You can access the Data Fitting routines through the Fortran and C89/C99 language interfaces. You can also use the C89 interface with more recent versions of C/C++, or the Fortran 90 interface with programs written in Fortran 95.

The `$(MKL)/include` directory of the Intel® MKL contains the following Data Fitting header files:

- `mkl_df.h`

You can find examples that demonstrate usage of Data Fitting routines in the `$(MKL)/examples/datafittingc` directory.

Naming Conventions

The interface of the Data Fitting functions, types, and constants are case-sensitive and can be in lowercase, uppercase, and mixed case.

The names of all routines have the following structure:

`df[datatype]<base_name>`

where

- `df` is a prefix indicating that the routine belongs to the Data Fitting component of Intel MKL.
- `[datatype]` field specifies the type of the input and/or output data and can be `s` (for the single precision real type), `d` (for the double precision real type), or `i` (for the integer type). This field is omitted in the names of the routines that are not data type dependent.
- `<base_name>` field specifies the functionality the routine performs. For example, this field can be `NewTask1D`, `Interpolate1D`, or `DeleteTask`

Data Types

The Data Fitting component provides routines for processing single and double precision real data types. The results of cell search operations are returned as a generic integer data type.

All Data Fitting routines use the following data type:

Type	Data Object
DFTaskPtr	Pointer to a task

NOTE

The actual size of the generic integer type is platform-dependent. Before compiling your application, you need to set an appropriate byte size for integers. For details, see section *Using the ILP64 Interface vs. LP64 Interface* of the Intel® MKL User's Guide.

Mathematical Conventions for Data Fitting Functions

This section explains the notation used for Data Fitting function descriptions. Spline notations are based on the terminology and definitions of [deBoor2001]. The Subbotin quadratic spline definition follows the conventions of [StechSub76]. The quasi-uniform partition definition is based on [Schumaker2007].

Mathematical Notation in the Data Fitting Component

Concept	Mathematical Notation
Partition of interpolation interval $[a, b]$, where x_i denotes breakpoints. $[x_i, x_{i+1})$ denotes a sub-interval (cell) of size $\Delta_i = x_{i+1} - x_i$.	$\{x_i\}_{i=1,\dots,n}$, where $a = x_1 < x_2 < \dots < x_n = b$
Quasi-uniform partition of interpolation interval $[a, b]$	Partition $\{x_i\}_{i=1,\dots,n}$ which meets the constraint with a constant C defined as $1 \leq M / m \leq C,$ where $M = \max_{i=1,\dots,n-1} (\Delta_i)$ $m = \min_{i=1,\dots,n-1} (\Delta_i)$ $\Delta_i = x_{i+1} - x_i$
Vector-valued function of dimension p being fit	$f(x) = (f_1(x), \dots, f_p(x))$
Piecewise polynomial (PP) function f of order $k+1$	$f(x) = P_i(x)$, if $x \in [x_i, x_{i+1})$, $i = 1, \dots, n-1$ where $\{x_i\}_{i=1,\dots,n}$ is a strictly increasing sequence of breakpoints. $P_i(x) = c_{i,0} + c_{i,1}(x - x_i) + \dots + c_{i,k}(x - x_i)^k$ is a polynomial of degree k (order $k+1$) over the interval $x \in [x_i, x_{i+1})$.
Function p agrees with function f at the points $\{x_i\}_{i=1,\dots,n}$.	For every point ζ in sequence $\{x_i\}_{i=1,\dots,n}$ that occurs m times, the equality $p^{(i-1)}(\zeta) = f^{(i-1)}(\zeta)$ holds for all $i = 1, \dots, m$, where $p^{(i)}(t)$ is the derivative of the i -th order.

Concept	Mathematical Notation
The k -th divided difference of function f at points $x_i, \dots, x_{i+k}$. This difference is the leading coefficient of the polynomial of order $k+1$ that agrees with f at $x_i, \dots, x_{i+k}$.	$[x_i, \dots, x_{i+k}] f$ In particular, $[x_1] f = f(x_1)$ $[x_1, x_2] f = (f(x_1) - f(x_2)) / (x_1 - x_2)$
A k -order derivative of interpolant $f(x)$ at interpolation site τ .	$f^{(k)}(\tau)$

Interpolants to the Function f at $x_1, \dots, x_n$ and Boundary Conditions

Concept	Mathematical Notation
Linear interpolant	$P_i(x) = c_{1,i} + c_{2,i}(x - x_i)$, where $x \in [x_i, x_{i+1})$ $c_{1,i} = f(x_i)$ $c_{2,i} = [x_i, x_{i+1}] f$ $i = 1, \dots, n-1$
Piecewise parabolic interpolant	$P_i(x) = c_{1,i} + c_{2,i}(x - x_i) + c_{3,i}(x - x_i)^2$, $x \in [x_i, x_{i+1})$ Coefficients $c_{1,i}$, $c_{2,i}$, and $c_{3,i}$ depend on the conditions: $P_i(x_i) = f(x_i)$ $P_i(x_{i+1}) = f(x_{i+1})$ $P_i((x_{i+1} + x_i) / 2) = v_{i+1}$ where parameter v_{i+1} depends on the interpolant being continuously differentiable: $P_{i-1}^{(1)}(x_i) = P_i^{(1)}(x_i)$
Piecewise parabolic Subbotin interpolant	$P(x) = P_i(x) = c_{1,i} + c_{2,i}(x - x_i) + c_{3,i}(x - x_i)^2 + d_{3,i}((x - t_i)_+)^2$, where $x \in [t_i, t_{i+1})$ $\{t_i\}_{i=1, \dots, n+1}$ is a sequence of knots such that $t_1 = x_1$, $t_{n+1} = x_n$ $t_i \in (x_{i-1}, x_i)$, $i = 2, \dots, n$ $x_+ = f(x) = \begin{cases} 0, & \text{if } x < 0 \\ x, & \text{if } x \geq 0 \end{cases}$ Coefficients $c_{1,i}$, $c_{2,i}$, $c_{3,i}$, and $d_{3,i}$ depend on the following conditions: $P_i(x_i) = f(x_i)$, $P_i(x_{i+1}) = f(x_{i+1})$ $P(x)$ is a continuously differentiable polynomial of the second degree on $[t_i, t_{i+1})$, $i = 1, \dots, n$.
Piecewise cubic Hermite interpolant	$P_i(x) = c_{1,i} + c_{2,i}(x - x_i) + c_{3,i}(x - x_i)^2 + c_{4,i}(x - x_i)^3$, where $x \in [x_i, x_{i+1})$ $c_{1,i} = f(x_i)$ $c_{2,i} = s_i$ $c_{3,i} = ([x_i, x_{i+1}] f - s_i) / (\Delta x_i) - c_{4,i}(\Delta x_i)$ $c_{4,i} = (s_i + s_{i+1} - 2[x_i, x_{i+1}] f) / (\Delta x_i)^2$

Concept	Mathematical Notation
	$i = 1, \dots, n-1$ $s_i = f^{(1)}(x_i)$
Piecewise cubic Bessel interpolant	$P_i(x) = c_{1,i} + c_{2,i}(x - x_i) + c_{3,i}(x - x_i)^2 + c_{4,i}(x - x_i)^3$, where $x \in [x_i, x_{i+1})$ $c_{1,i} = f(x_i)$ $c_{2,i} = s_i$ $c_{3,i} = ([x_i, x_{i+1}]f - s_i) / (\Delta x_i) - c_{4,i}(\Delta x_i)$ $c_{4,i} = (s_i + s_{i+1} - 2[x_i, x_{i+1}]f) / (\Delta x_i)^2$ $i = 1, \dots, n-1$ $s_i = (\Delta x_i[x_{i-1}, x_i]f + \Delta x_{i-1}[x_i, x_{i+1}]f) / (\Delta x_i + \Delta x_{i+1})$
Piecewise cubic Akima interpolant	$P_i(x) = c_{1,i} + c_{2,i}(x - x_i) + c_{3,i}(x - x_i)^2 + c_{4,i}(x - x_i)^3$, where $x \in [x_i, x_{i+1})$ $c_{1,i} = f(x_i)$ $c_{2,i} = s_i$ $c_{3,i} = ([x_i, x_{i+1}]f - s_i) / (\Delta x_i) - c_{4,i}(\Delta x_i)$ $c_{4,i} = (s_i + s_{i+1} - 2[x_i, x_{i+1}]f) / (\Delta x_i)^2$ $i = 1, \dots, n-1$ $s_i = (w_{i+1}[x_{i-1}, x_i]f + w_{i-1}[x_i, x_{i+1}]f) / (w_{i+1} + w_{i-1})$, where $w_i = [x_i, x_{i+1}]f - [x_{i-1}, x_i]f$
Piecewise natural cubic interpolant	$P_i(x) = c_{1,i} + c_{2,i}(x - x_i) + c_{3,i}(x - x_i)^2 + c_{4,i}(x - x_i)^3$, where $x \in [x_i, x_{i+1})$ $c_{1,i} = f(x_i)$ $c_{2,i} = s_i$ $c_{3,i} = ([x_i, x_{i+1}]f - s_i) / (\Delta x_i) - c_{4,i}(\Delta x_i)$ $c_{4,i} = (s_i + s_{i+1} - 2[x_i, x_{i+1}]f) / (\Delta x_i)^2$ $i = 1, \dots, n-1$ - Parameter s_i depends on the condition that the interpolant is twice continuously differentiable: $P_{i-1}^{(2)}(x_i) = P_i^{(2)}(x_i)$.
Not-a-knot boundary condition.	Parameters s_1 and s_n provide $P_1 = P_2$ and $P_{n-1} = P_n$, so that the first and the last interior breakpoints are inactive.
Free-end boundary condition.	$f''(x_1) = f''(x_n) = 0$
Look-up interpolator for discrete set of points $(x_1, y_1), \dots, (x_n, y_n)$.	$y(x) = \begin{cases} y_1, & \text{if } x = x_1 \\ y_2, & \text{if } x = x_2 \\ \dots & \dots \\ y_n, & \text{if } x = x_n \\ \text{error,} & \text{otherwise} \end{cases}$

Concept	Mathematical Notation
Step-wise constant continuous right interpolator.	$y(x) = \begin{cases} y_1, & \text{if } x_1 \leq x < x_2 \\ y_2, & \text{if } x_2 \leq x < x_3 \\ \dots & \dots \\ y_{n-1}, & \text{if } x_{n-1} \leq x < x_n \\ y_n, & \text{if } x = x_n \end{cases}$
Step-wise constant continuous left interpolator.	$y(x) = \begin{cases} y_1, & \text{if } x = x_1 \\ y_2, & \text{if } x_1 < x \leq x_2 \\ y_3, & \text{if } x_2 < x \leq x_3 \\ \dots & \dots \\ y_n, & \text{if } x_{n-1} < x \leq x_n \end{cases}$

Data Fitting Usage Model

Consider an algorithm that uses the Data Fitting functions. Typically, such algorithms consist of four steps or stages:

1. Create a task. You can call the Data Fitting function several times to create multiple tasks.

```
status = dfdNewTask1D( &task, nx, x, xhint, ny, y, yhint );
```

2. Modify the task parameters.

```
status = dfdEditPPSpline1D( task, s_order, c_type, bc_type, bc, ic_type, ic,
scoeff, scoeffhint );
```

3. Perform Data Fitting spline-based computations. You may reiterate steps 2-3 as needed.

```
status = dfdInterpolate1D(task, estimate, method, nsite, site, sitehint, ndorder,
dorder, datahint, r, rhint, cell );
```

4. Destroy the task or tasks.

```
status = dfDeleteTask( &task );
```

Data Fitting Usage Examples

The examples below illustrate several operations that you can perform with Data Fitting routines.

You can get source code for similar examples in the `.\examples\datafittingc` subdirectory of the Intel MKL installation directory.

The following example demonstrates the construction of a linear spline using Data Fitting routines. The spline approximates a scalar function defined on non-uniform partition. The coefficients of the spline are returned as a one-dimensional array:

Example of Linear Spline Construction

```
#include "mkl.h"
#define N 500 /* Size of partition, number of breakpoints */
#define SPLINE_ORDER DF_PP_LINEAR /* Linear spline to construct */

int main()
```

```

{
    int status;          /* Status of a Data Fitting operation */
    DFTaskPtr task;      /* Data Fitting operations are task based */

    /* Parameters describing the partition */
    MKL_INT nx;          /* The size of partition x */
    double x[N];         /* Partition x */
    MKL_INT xhint;       /* Additional information about the structure of breakpoints */

    /* Parameters describing the function */
    MKL_INT ny;          /* Function dimension */
    double y[N];         /* Function values at the breakpoints */
    MKL_INT yhint;       /* Additional information about the function */

    /* Parameters describing the spline */
    MKL_INT s_order;     /* Spline order */
    MKL_INT s_type;      /* Spline type */
    MKL_INT ic_type;     /* Type of internal conditions */
    double* ic;          /* Array of internal conditions */
    MKL_INT bc_type;     /* Type of boundary conditions */
    double* bc;          /* Array of boundary conditions */

    double scoeff[(N-1)* SPLINE_ORDER]; /* Array of spline coefficients */
    MKL_INT scoeffhint;  /* Additional information about the coefficients */

    /* Initialize the partition */
    nx = N;
    /* Set values of partition x */
    ...
    xhint = DF_NO_HINT; /* No additional information about the function is provided.
                        By default, the partition is non-uniform. */
    /* Initialize the function */
    ny = 1;             /* The function is scalar. */

    /* Set function values */
    ...
    yhint = DF_NO_HINT; /* No additional information about the function is provided. */

    /* Create a Data Fitting task */
    status = dfdNewTask1D( &task, nx, x, xhint, ny, y, yhint );

    /* Check the Data Fitting operation status */
    ...

    /* Initialize spline parameters */
    s_order = DF_PP_LINEAR; /* Spline is of the second order. */
    s_type = DF_PP_DEFAULT; /* Spline is of the default type. */

    /* Define internal conditions for linear spline construction (none in this example) */
    ic_type = DF_NO_IC;
    ic = NULL;

    /* Define boundary conditions for linear spline construction (none in this example) */
    bc_type = DF_NO_BC;
    bc = NULL;
    scoeffhint = DF_NO_HINT; /* No additional information about the spline. */

    /* Set spline parameters in the Data Fitting task */
    status = dfdEditPPSpline1D( task, s_order, s_type, bc_type, bc, ic_type,
                                ic, scoeff, scoeffhint );
}

```

```

/* Check the Data Fitting operation status */
...

/* Use a standard computation method to construct a linear spline: */
/*  $P_i(x) = c_{i,0} + c_{i,1}(x - x_i)$ ,  $i=0, \dots, N-2$  */
/* The library packs spline coefficients to array scoeff. */
/*  $scoeff[2*i+0] = c_{i,0}$  and  $scoeff[2*i+1] = c_{i,1}$ ,  $i=0, \dots, N-2$  */
status = dfdConstruct1D( task, DF_PP_SPLINE, DF_METHOD_STD );

/* Check the Data Fitting operation status */
...

/* Process spline coefficients */
...

/* Deallocate Data Fitting task resources */
status = dfDeleteTask( &task );

/* Check the Data Fitting operation status */
...
return 0 ;
}

```

The following example demonstrates cubic spline-based interpolation using Data Fitting routines. In this example, a scalar function defined on non-uniform partition is approximated by Bessel cubic spline using not-a-knot boundary conditions. Once the spline is constructed, you can use the spline to compute spline values at the given sites. Computation results are packed by the Data Fitting routine in row-major format.

Example of Cubic Spline-Based Interpolation

```

#include "mkl.h"

#define NX 100                /* Size of partition, number of breakpoints */
#define NSITE 1000           /* Number of interpolation sites */
#define SPLINE_ORDER DF_PP_CUBIC /* A cubic spline to construct */

int main()
{
    int status;                /* Status of a Data Fitting operation */
    DFTaskPtr task;            /* Data Fitting operations are task based */

    /* Parameters describing the partition */
    MKL_INT nx;                /* The size of partition x */
    double x[NX];              /* Partition x */
    MKL_INT xhint;             /* Additional information about the structure of breakpoints */

    /* Parameters describing the function */
    MKL_INT ny;                /* Function dimension */
    double y[NX];              /* Function values at the breakpoints */
    MKL_INT yhint;             /* Additional information about the function */

    /* Parameters describing the spline */
    MKL_INT s_order;           /* Spline order */
    MKL_INT s_type;            /* Spline type */
    MKL_INT ic_type;           /* Type of internal conditions */
    double* ic;                /* Array of internal conditions */
    MKL_INT bc_type;           /* Type of boundary conditions */
    double* bc;                /* Array of boundary conditions */

    double scoeff[(NX-1)*SPLINE_ORDER]; /* Array of spline coefficients */
}

```

```

/* Check Data Fitting operation status */
...

/* De-allocate Data Fitting task resources */
status = dfDeleteTask( &task );
/* Check Data Fitting operation status */
...
return 0;
}

```

The following example demonstrates how to compute indices of cells containing given sites. This example uses uniform partition presented with two boundary points. The sites are in the ascending order.

Example of Cell Search

```

#include "mkl.h"

#define NX 100 /* Size of partition, number of breakpoints */
#define NSITE 1000 /* Number of interpolation sites */

int main()
{
    int status; /* Status of a Data Fitting operation */
    DFTaskPtr task; /* Data Fitting operations are task based */

    /* Parameters describing the partition */
    MKL_INT nx; /* The size of partition x */
    float x[2]; /* Partition x is uniform and holds endpoints
                of interpolation interval [a, b] */
    MKL_INT xhint; /* Additional information about the structure of breakpoints */

```

```

/* Parameters describing the function */
MKL_INT ny;          /* Function dimension */
float *y;            /* Function values at the breakpoints */
MKL_INT yhint;       /* Additional information about the function */

/* Parameters describing cell search */
MKL_INT nsite;        /* Number of interpolation sites */
float site[NSITE];    /* Array of interpolation sites */
MKL_INT sitehint;     /* Additional information about the structure of sites */

float* datahint;      /* Additional information on partition and interpolation sites */

MKL_INT cell[NSITE];  /* Array for cell indices */

/* Initialize a uniform partition */
nx = NX;
/* Set values of partition x: for uniform partition,          */
/* provide end-points of the interpolation interval [-1.0,1.0] */
x[0] = -1.0f; x[1] = 1.0f;
xhint = DF_UNIFORM_PARTITION; /* Partition is uniform */

/* Initialize function parameters */
/* In cell search, function values are not necessary and are set to zero/NULL values */
ny = 0;
y = NULL;
yhint = DF_NO_HINT;

/* Create a Data Fitting task */
status = dfsNewTask1D( &task, nx, x, xhint, ny, y, yhint );

/* Check Data Fitting operation status */
...

/* Initialize interpolation (cell search) parameters */
nsite = NSITE;

/* Set sites in the ascending order */
...
sitehint = DF_SORTED_DATA; /* Sites are provided in the ascending order. */
datahint = DF_NO_APRIORI_INFO; /* No additional information
                                about breakpoints/sites is provided.*/

/* Use a standard method to compute indices of the cells that contain
   interpolation sites. The library places the index of the cell containing
   site(i) to the cell(i), i=0,...,nsite-1 */
status = dfsSearchCells1D( task, DF_METHOD_STD, nsite, site, sitehint,
                           datahint, cell );
/* Check Data Fitting operation status */
...

/* Process cell indices */
...

/* Deallocate Data Fitting task resources */
status = dfDeleteTask( &task );

/* Check Data Fitting operation status */
...
return 0;
}

```

Task Status and Error Reporting

The Data Fitting routines report a task status through integer values. Negative status values indicate errors, while positive values indicate warnings. An error can be caused by invalid parameter values or a memory allocation failure.

The status codes have symbolic names predefined in the header file as macros via the `#define` statements.

If no error occurred, the function returns the `DF_STATUS_OK` code defined as zero:

```
#define DF_STATUS_OK 0
```

In case of an error, the function returns a non-zero error code that specifies the origin of the failure. Header files define the following status codes:

Status Codes in the Data Fitting Component

Status Code	Description
Common Status Codes	
<code>DF_STATUS_OK</code>	Operation completed successfully.
<code>DF_ERROR_NULL_TASK</code>	Data Fitting task is a <code>NULL</code> pointer.
<code>DF_ERROR_MEM_FAILURE</code>	Memory allocation failure.
<code>DF_ERROR_METHOD_NOT_SUPPORTED</code>	Requested method is not supported.
<code>DF_ERROR_COMP_TYPE_NOT_SUPPORTED</code>	Requested computation type is not supported.
<code>DF_ERROR_NULL_PTR</code>	Pointer to parameter is null.
Data Fitting Task Creation and Initialization, and Generic Editing Operations	
<code>DF_ERROR_BAD_NX</code>	Invalid number of breakpoints.
<code>DF_ERROR_BAD_X</code>	Array of breakpoints is invalid.
<code>DF_ERROR_BAD_X_HINT</code>	Invalid hint describing the structure of the partition.
<code>DF_ERROR_BAD_NY</code>	Invalid dimension of vector-valued function y .
<code>DF_ERROR_BAD_Y</code>	Array of function values is invalid.
<code>DF_ERROR_BAD_Y_HINT</code>	Invalid flag describing the structure of function y
Data Fitting Task-Specific Editing Operations	
<code>DF_ERROR_BAD_SPLINE_ORDER</code>	Invalid spline order.
<code>DF_ERROR_BAD_SPLINE_TYPE</code>	Invalid spline type.
<code>DF_ERROR_BAD_IC_TYPE</code>	Type of internal conditions used for spline construction is invalid.
<code>DF_ERROR_BAD_IC</code>	Array of internal conditions for spline construction is not defined.
<code>DF_ERROR_BAD_BC_TYPE</code>	Type of boundary conditions used in spline construction is invalid.
<code>DF_ERROR_BAD_BC</code>	Array of boundary conditions for spline construction is not defined.
<code>DF_ERROR_BAD_PP_COEFF</code>	Array of piecewise polynomial spline coefficients is not defined.

Status Code	Description
DF_ERROR_BAD_PP_COEFF_HINT	Invalid flag describing the structure of the piecewise polynomial spline coefficients.
DF_ERROR_BAD_PERIODIC_VAL	Function values at the endpoints of the interpolation interval are not equal as required in periodic boundary conditions.
DF_ERROR_BAD_DATA_ATTR	Invalid attribute of the pointer to be set or modified in Data Fitting task descriptor with the <code>df?</code> <code>EditIdxPtr</code> task editor.
DF_ERROR_BAD_DATA_IDX	Index of the pointer to be set or modified in the Data Fitting task descriptor with the <code>df?</code> <code>EditIdxPtr</code> task editor is out of the pre-defined range.
Data Fitting Computation Operations	
DF_ERROR_BAD_NSITE	Invalid number of interpolation sites.
DF_ERROR_BAD_SITE	Array of interpolation sites is not defined.
DF_ERROR_BAD_SITE_HINT	Invalid flag describing the structure of interpolation sites.
DF_ERROR_BAD_NDORDER	Invalid size of the array defining derivative orders to be computed at interpolation sites.
DF_ERROR_BAD_DORDER	Array defining derivative orders to be computed at interpolation sites is not defined.
DF_ERROR_BAD_DATA_HINT	Invalid flag providing additional information about partition or interpolation sites.
DF_ERROR_BAD_INTERP	Array of spline-based interpolation results is not defined.
DF_ERROR_BAD_INTERP_HINT	Invalid flag defining the structure of spline-based interpolation results.
DF_ERROR_BAD_CELL_IDX	Array of indices of partition cells containing interpolation sites is not defined.
DF_ERROR_BAD_NLIM	Invalid size of arrays containing integration limits.
DF_ERROR_BAD_LLM	Array of the left-side integration limits is not defined.
DF_ERROR_BAD_RLM	Array of the right-side integration limits is not defined.
DF_ERROR_BAD_INTEGR	Array of spline-based integration results is not defined.
DF_ERROR_BAD_INTEGR_HINT	Invalid flag providing the structure of the array of spline-based integration results.
DF_ERROR_BAD_LOOKUP_INTERP_SITE	Bad site provided for interpolation with look-up interpolator.

NOTE

The routine that estimates piecewise polynomial cubic spline coefficients can return internal error codes related to the specifics of the implementation. Such error codes indicate invalid input data or other issues unrelated to Data Fitting routines.

Task Creation and Initialization Routines

Task creation and initialization routines are functions used to create a new task descriptor and initialize its parameters. The Data Fitting component provides the `df?NewTask1D` routine that creates and initializes a new task descriptor for a one-dimensional Data Fitting task.

`df?NewTask1D`

Creates and initializes a new task descriptor for a one-dimensional Data Fitting task.

Syntax

```
status = dfsNewTask1D(&task, nx, x, xhint, ny, y, yhint)
```

```
status = dfdNewTask1D(&task, nx, x, xhint, ny, y, yhint)
```

Include Files

- `mk1.h`

Input Parameters

Name	Type	Description
<code>nx</code>	<code>const MKL_INT</code>	Number of breakpoints representing partition of interpolation interval $[a, b]$.
<code>x</code>	One-dimensional array containing the strictly sorted breakpoints from interpolation interval $[a, b]$. The structure of the array is defined by parameter <code>xhint</code> : • If partition is non-uniform or quasi-uniform, the array should contain <code>nx</code> strictly ordered values. • If partition is uniform, the array should contain two entries that represent endpoints of interpolation interval $[a, b]$.	
<code>xhint</code>	<code>const MKL_INT</code>	A flag describing the structure of partition <code>x</code> . For the list of possible values of <code>xhint</code> , see table " Hint Values for Partition x ". If you set the flag to the <code>DF_NO_HINT</code> value, the library interprets the partition as non-uniform.

Name	Type	Description
<i>ny</i>	const MKL_INT	Dimension of vector-valued function <i>y</i> .
<i>y</i>	const float* for <code>dfsNewTask</code> const double* for <code>dfdNewTask</code>	Vector-valued function <i>y</i> , array of size $n_x \times n_y$. The storage format of function values in the array is defined by the value of flag <i>yhint</i> .
<i>yhint</i>	const MKL_INT	A flag describing the structure of array <i>y</i> . Valid hint values are listed in table " Hint Values for Vector-Valued Function <i>y</i> ". If you set the flag to the <code>DF_NO_HINT</code> value, the library assumes that all <i>ny</i> coordinates of the vector-valued function <i>y</i> are provided and stored in row-major format.

Output Parameters

Name	Type	Description
<i>task</i>	DFTaskPtr	Descriptor of the task.
<i>status</i>	int	Status of the routine: <code>DF_STATUS_OK</code> if the task is created successfully. - Non-zero error code if the task creation failed. See "Task Status and Error Reporting" for error code definitions.

Description

The `df?NewTask1D` routine creates and initializes a new Data Fitting task descriptor with user-specified parameters for a one-dimensional Data Fitting task. The *x* and *nx* parameters representing the partition of interpolation interval $[a, b]$ are mandatory. If you provide invalid values for these parameters, such as a NULL pointer *x* or the number of breakpoints smaller than two, the routine does not create the Data Fitting task and returns an error code.

If you provide a vector-valued function *y*, make sure that the function dimension *ny* and the array of function values *y* are both valid. If any of these parameters are invalid, the routine does not create the Data Fitting task and returns an error code.

If you store coordinates of the vector-valued function *y* in non-contiguous memory locations, you can set the *yhint* flag to `DF_1ST_COORDINATE`, and pass only the first coordinate of the function into the task creation routine. After successful creation of the Data Fitting task, you can pass the remaining coordinates using the `df?EditIdxPtr` task editor.

If the routine fails to create the task descriptor, it returns a NULL task pointer.

The routine supports the following hint values for partition *x*:

Hint Values for Partition *x*

Value	Description
<code>DF_NON_UNIFORM_PARTITION</code>	Partition is non-uniform.
<code>DF_QUASI_UNIFORM_PARTITION</code>	Partition is quasi-uniform.
<code>DF_UNIFORM_PARTITION</code>	Partition is uniform.
<code>DF_NO_HINT</code>	No hint is provided. By default, partition is interpreted as non-uniform.

The routine supports the following hint values for the vector-valued function:

Hint Values for Vector-Valued Function y

Value	Description
DF_MATRIX_STORAGE_ROWS	Data is stored in row-major format according to C conventions.
DF_MATRIX_STORAGE_COLS	Data is stored in column-major format according to Fortran conventions.
DF_1ST_COORDINATE	The first coordinate of vector-valued data is provided.
DF_NO_HINT	No hint is provided. By default, the coordinates of vector-valued function y are provided and stored in row-major format.

NOTE

You must preserve the arrays x (breakpoints) and y (vector-valued functions) through the entire workflow of the Data Fitting computations for a task, as the task stores the addresses of the arrays for spline-based computations.

Task Configuration Routines

In order to configure tasks, you can use task editors and task query routines.

Task editors initialize or change the predefined Data Fitting task parameters. You can use task editors to initialize or modify pointers to arrays or parameter values.

Task editors can be task-specific or generic. Task-specific editors can modify more than one parameter related to a specific task. Generic editors modify a single parameter at a time.

The Data Fitting component of Intel MKL provides the following task editors:

Data Fitting Task Editors

Editor	Description	Type
<code>df?</code> <code>EditPPSpline1D</code>	Changes parameters of the piecewise polynomial spline.	Task-specific
<code>df?EditPtr</code>	Changes a pointer in the task descriptor.	Generic
<code>dfiEditVal</code>	Changes a value in the task descriptor.	Generic
<code>df?EditIdxPtr</code>	Changes a coordinate of data represented in matrix format, such as a vector-valued function or spline coefficients.	Generic

Task query routines are used to read the predefined Data Fitting task parameters. You can use task query routines to read the values of pointers or parameters.

Task query routines are generic (not task-specific), allowing you to read a single parameter at a time.

The Data Fitting component of the Intel MKL provides the following task query routines:

Data Fitting Task Query Routines

Editor	Description	Type
<code>df?QueryPtr</code>	Queries a pointer in the task descriptor.	Generic
<code>dfiQueryVal</code>	Queries a value in the task descriptor.	Generic

Editor	Description	Type
<code>df?QueryIdxPtr</code>	Queries a coordinate of data represented in matrix format, such as a vector-valued function or spline coefficients.	Generic

df?EditPPSpline1D

Modifies parameters representing a spline in a Data Fitting task descriptor.

Syntax

```
status = dfsEditPPSpline1D(task, s_order, s_type, bc_type, bc, ic_type, ic, scoeff,
scoeffhint)
```

```
status = dfdEditPPSpline1D(task, s_order, s_type, bc_type, bc, ic_type, ic, scoeff,
scoeffhint)
```

Include Files

- `mkl.h`

Input Parameters

Name	Type	Description
<code>task</code>	<code>DFTaskPtr</code>	Descriptor of the task.
<code>s_order</code>	<code>const MKL_INT</code>	Spline order. The parameter takes one of the values described in table "Spline Orders Supported by Data Fitting Functions" .
<code>s_type</code>	<code>const MKL_INT</code>	Spline type. The parameter takes one of the values described in table "Spline Types Supported by Data Fitting Functions" .
<code>bc_type</code>	<code>const MKL_INT</code>	Type of boundary conditions. The parameter takes one of the values described in table "Boundary Conditions Supported by Data Fitting Functions" .
<code>bc</code>	<code>const float*</code> for <code>dfsEditPPSpline1D</code> <code>const double*</code> for <code>dfdEditPPSpline1D</code>	Pointer to boundary conditions. The size of the array is defined by the value of parameter <code>bc_type</code> : • If you set free-end or not-a-knot boundary conditions, pass the <code>NULL</code> pointer to this parameter. • If you combine boundary conditions at the endpoints of the interpolation interval, pass an array of two elements. • If you set a boundary condition for the default quadratic spline or a periodic condition for Hermite or the default cubic spline, pass an array of one element.
<code>ic_type</code>	<code>const MKL_INT</code>	Type of internal conditions. The parameter takes one of the values described in table "Internal Conditions Supported by Data Fitting Functions" .

Name	Type	Description
<i>ic</i>	const float* for dfsEditPPSpline1D const double* for dfdEditPPSpline1D	A non-NULL pointer to the array of internal conditions. The size of the array is defined by the value of parameter <i>ic_type</i>: - If you set first derivatives or second derivatives internal conditions (<i>ic_type</i>=DF_IC_1ST_DER or <i>ic_type</i>=DF_IC_2ND_DER), pass an array of <i>n</i>-1 derivative values at the internal points of the interpolation interval. - If you set the knot values internal condition for Subbotin spline (<i>ic_type</i>=DF_IC_Q_KNOT) and the knot partition is non-uniform, pass an array of <i>n</i>+1 elements. - If you set the knot values internal condition for Subbotin spline (<i>ic_type</i>=DF_IC_Q_KNOT) and the knot partition is uniform, pass an array of four elements.
<i>scoeff</i>	const float* for dfsEditPPSpline1D const double* for dfdEditPPSpline1D	Spline coefficients. An array of size <i>ny*s_order*(nx-1)</i> . The storage format of the coefficients in the array is defined by the value of flag <i>scoeffhint</i> .
<i>scoeffhint</i>	const MKL_INT	A flag describing the structure of the array of spline coefficients. For valid hint values, see table " Hint Values for Spline Coefficients ". The library stores the coefficients in row-major format. The default value is DF_NO_HINT.

Output Parameters

Name	Type	Description
<i>status</i>	int	Status of the routine: - DF_STATUS_OK if the routine execution completed successfully. - Non-zero error code if the routine execution failed. See "Task Status and Error Reporting" for error code definitions.

Description

The editor modifies parameters that describe the order, type, boundary conditions, internal conditions, and coefficients of a spline. The spline order definition is provided in the "[Mathematical Conventions](#)" section. You can set the spline order to any value supported by Data Fitting functions. The table below lists the available values:

Spline Orders Supported by the Data Fitting Functions

Order	Description
DF_PP_STD	Artificial value. Use this value for look-up and step-wise constant interpolants only.
DF_PP_LINEAR	Piecewise polynomial spline of the second order (linear spline).

Order	Description
DF_PP_QUADRATIC	Piecewise polynomial spline of the third order (quadratic spline).
DF_PP_CUBIC	Piecewise polynomial spline of the fourth order (cubic spline).

To perform computations with a spline not supported by Data Fitting routines, set the parameter defining the spline order and pass the spline coefficients to the library in the supported format. For format description, see figure "Row-major Coefficient Storage Format".

The table below lists the supported spline types:

Spline Types Supported by Data Fitting Functions

Type	Description
DF_PP_DEFAULT	The default spline type. You can use this type with linear, quadratic, or user-defined splines.
DF_PP_SUBBOTIN	Quadratic splines based on Subbotin algorithm, [StechSub76].
DF_PP_NATURAL	Natural cubic spline.
DF_PP_HERMITE	Hermite cubic spline.
DF_PP_BESSEL	Bessel cubic spline.
DF_PP_AKIMA	Akima cubic spline.
DF_LOOKUP_INTERPOLANT	Look-up interpolant.
DF_CR_STEPWISE_CONST_INTERPOLANT	Continuous right step-wise constant interpolant.
DF_CL_STEPWISE_CONST_INTERPOLANT	Continuous left step-wise constant interpolant.

If you perform computations with look-up or step-wise constant interpolants, set the spline order to the DF_PP_STD value.

Construction of specific splines may require boundary or internal conditions. To compute coefficients of such splines, you should pass boundary or internal conditions to the library by specifying the type of the conditions and providing the necessary values. For splines that do not require additional conditions, such as linear splines, set condition types to DF_NO_BC and DF_NO_IC, and pass NULL pointers to the conditions. The table below defines the supported boundary conditions:

Boundary Conditions Supported by Data Fitting Functions

Boundary Condition	Description	Spline
DF_NO_BC	No boundary conditions provided.	All
DF_BC_NOT_A_KNOT	Not-a-knot boundary conditions.	Akima, Bessel, Hermite, natural cubic
DF_BC_FREE_END	Free-end boundary conditions.	Akima, Bessel, Hermite, natural cubic, quadratic Subbotin
DF_BC_1ST_LEFT_DER	The first derivative at the left endpoint.	Akima, Bessel, Hermite, natural cubic, quadratic Subbotin

Boundary Condition	Description	Spline
DF_BC_1ST_RIGHT_DER	The first derivative at the right endpoint.	Akima, Bessel, Hermite, natural cubic, quadratic Subbotin
DF_BC_2ST_LEFT_DER	The second derivative at the left endpoint.	Akima, Bessel, Hermite, natural cubic, quadratic Subbotin
DF_BC_2ND_RIGHT_DER	The second derivative at the right endpoint.	Akima, Bessel, Hermite, natural cubic, quadratic Subbotin
DF_BC_PERIODIC	Periodic boundary conditions.	Linear, all cubic splines
DF_BC_Q_VAL	Function value at point $(x_0 + x_1)/2$	Default quadratic

NOTE

To construct a natural cubic spline, pass these settings to the editor:

- DF_PP_CUBIC as the spline order,
- DF_PP_NATURAL as the spline type, and
- DF_BC_FREE_END as the boundary condition.

To construct a cubic spline with other boundary conditions, pass these settings to the editor:

- DF_PP_CUBIC as the spline order,
- DF_PP_NATURAL as the spline type, and
- the required type of boundary condition.

For Akima, Hermite, Bessel and default cubic splines use the corresponding type defined in [Table Spline Types Supported by Data Fitting Functions](#).

You can combine the values of boundary conditions with a bitwise OR operation. This permits you to pass combinations of first and second derivatives at the endpoints of the interpolation interval into the library. To pass a first derivative at the left endpoint and a second derivative at the right endpoint, set the boundary conditions to DF_BC_1ST_LEFT_DER OR DF_BC_2ND_RIGHT_DER.

You should pass the combined boundary conditions as an array of two elements. The first entry of the array contains the value of the boundary condition for the left endpoint of the interpolation interval, and the second entry - for the right endpoint. Pass other boundary conditions as arrays of one element.

For the conditions defined as a combination of valid values, the library applies the following rules to identify the boundary condition type:

- If not required for spline construction, the value of boundary conditions is ignored.
- Not-a-knot condition has the highest priority. If set, other boundary conditions are ignored.
- Free-end condition has the second priority after the not-a-knot condition. If set, other boundary conditions are ignored.
- Periodic boundary condition has the next priority after the free-end condition.
- The first derivative has higher priority than the second derivative at the right and left endpoints.

If you set the periodic boundary condition, make sure that function values at the endpoints of the interpolation interval are identical. Otherwise, the library returns an error code. The table below specifies the values to be provided for each type of spline if the periodic boundary condition is set.

Boundary Requirements for Periodic Conditions

Spline Type	Periodic Boundary Condition Support	Boundary Value
Linear	Yes	Not required
Default quadratic	No	
Subbotin quadratic	No	
Natural cubic	Yes	Not required
Bessel	Yes	Not required
Akima	Yes	Not required
Hermite cubic	Yes	First derivative
Default cubic	Yes	Second derivative

Internal conditions supported in the Data Fitting domain that you can use for the *ic_type* parameter are the following:

Internal Conditions Supported by Data Fitting Functions

Internal Condition	Description	Spline
DF_NO_IC	No internal conditions provided.	
DF_IC_1ST_DER	Array of first derivatives of size $n-2$, where n is the number of breakpoints. Derivatives are applicable to each coordinate of the vector-valued function.	Hermite cubic
DF_IC_2ND_DER	Array of second derivatives of size $n-2$, where n is the number of breakpoints. Derivatives are applicable to each coordinate of the vector-valued function.	Default cubic
DF_IC_Q_KNOT	Knot array of size $n+1$, where n is the number of breakpoints.	Subbotin quadratic

To construct a Subbotin quadratic spline, you have three options to get the array of knots in the library:

- If you do not provide the knots, the library uses the default values of knots $t = \{t_i\}$, $i = 0, \dots, n$ according to the rule:

$$t_0 = x_0, t_n = x_{n-1}, t_i = (x_i + x_{i-1})/2, i = 1, \dots, n-1.$$

- If you provide the knots in an array of size $n+1$, the knots form a non-uniform partition. Make sure that the knot values you provide meet the following conditions:

$$t_0 = x_0, t_n = x_{n-1}, t_i \in (x_{i-1}, x_i), i = 1, \dots, n-1.$$

- If you provide the knots in an array of size 4, the knots form a uniform partition

$$t_0 = x_0, t_1 = l, t_2 = r, t_3 = x_{n-1}, \text{ where } l \in (x_0, x_1) \text{ and } r \in (x_{n-2}, x_{n-1}).$$

In this case, you need to set the value of the *ic_type* parameter holding the type of internal conditions to DF_IC_Q_KNOT OR DF_UNIFORM_PARTITION.

NOTE

Since the partition is uniform, perform an OR operation with the `DF_UNIFORM_PARTITION` partition hint value described in [Table Hint Values for Partition x](#).

For computations based on look-up and step-wise constant interpolants, you can avoid calling the `df?EditPPSpline1D` editor and directly call one of the routines for spline-based computation of spline values, derivatives, or integrals. For example, you can call the `df?Construct1D` routine to construct the required spline with the given attributes, such as order or type.

The memory location of the spline coefficients is defined by the `scoeff` parameter. Make sure that the size of the array is sufficient to hold $ny * s\_order * (nx-1)$ values.

The `df?EditPPSpline1D` routine supports the following hint values for spline coefficients:

Hint Values for Spline Coefficients

Order	Description
<code>DF_1ST_COORDINATE</code>	The first coordinate of vector-valued data is provided.
<code>DF_NO_HINT</code>	No hint is provided. By default, all sets of spline coefficients are stored in row-major format.

The coefficients for all coordinates of the vector-valued function are packed in memory one by one in successive order, from function y_1 to function y_{ny} .

Within each coordinate, the library stores the coefficients as an array, in row-major format:

$c_{1,0}, c_{1,1}, \dots, c_{1,k}, c_{2,0}, c_{2,1}, \dots, c_{2,k}, \dots, c_{n-1,0}, c_{n-1,1}, \dots, c_{n-1,k}$

Mapping of the coefficients to storage in the `scoeff` array is described below, where $c_{i,j}$ is the j th coefficient of the function

$$P_i(x) = c_{i,0} + c_{i,1}(x-x_i) + \dots + c_{i,k}(x-x_i)^k$$

See [Mathematical Conventions](#) for more details on nomenclature and interpolants.

Row-major Coefficient Storage Format

$$\begin{aligned}
 P_1(x) &= \overrightarrow{c_{1,0}} + \overrightarrow{c_{1,1}(x-x_1)} + \overrightarrow{\dots} + \overrightarrow{c_{1,k}(x-x_1)^k} \\
 P_2(x) &= \overrightarrow{c_{2,0}} + \overrightarrow{c_{2,1}(x-x_2)} + \overrightarrow{\dots} + \overrightarrow{c_{2,k}(x-x_2)^k} \\
 &\quad \vdots \\
 P_{n-1}(x) &= \overrightarrow{c_{n-1,0}} + \overrightarrow{c_{n-1,1}(x-x_{n-1})} + \overrightarrow{\dots} + \overrightarrow{c_{n-1,k}(x-x_{n-1})^k}
 \end{aligned}$$

If you store splines corresponding to different coordinates of the vector-valued function at non-contiguous memory locations, do the following:

1. Set the `scoeffhint` flag to `DF_1ST_COORDINATE` and provide the spline for the first coordinate.
2. Pass the spline coefficients for the remaining coordinates into the Data Fitting task using the `df?EditIdxPtr` task editor.

Using the `df?EditPPSpline1D` task editor, you can provide to the Data Fitting task an already constructed spline that you want to use in computations. To ensure correct interpretation of the memory content, you should set the following parameters:

- Spline order and type, if appropriate. If the spline is not supported by the library, set the `s_type` parameter to `DF_PP_DEFAULT`.
- Pointer to the array of spline coefficients in row-major format.
- The `scoeffhint` parameter describing the structure of the array:
 - Set the `scoeffhint` flag to the `DF_1ST_COORDINATE` value to pass spline coefficients stored at different memory locations. In this case, you can set the parameters that describe boundary and internal conditions to zero.
 - Use the default value `DF_NO_HINT` for all other cases.

Before passing an already constructed spline into the library, you should call the `dfiEditVal` task editor to provide the dimension of the spline `DF_NY`. See table "Parameters Supported by the `dfiEditVal` Task Editor" for details.

After you provide the spline to the Data Fitting task, you can run computations that use this spline.

NOTE

You must preserve the arrays `bc` (boundary conditions), `ic` (internal conditions), and `scoeff` (spline coefficients) through the entire workflow of the Data Fitting computations for a task, as the task stores the addresses of the arrays for spline-based computations.

`df?EditPtr`

Modifies a pointer to an array held in a Data Fitting task descriptor.

Syntax

```
status = dfsEditPtr(task, ptr_attr, ptr)
```

```
status = dfdEditPtr(task, ptr_attr, ptr)
```

Include Files

- `mkl.h`

Input Parameters

Name	Type	Description
<code>task</code>	<code>DFTaskPtr</code>	Descriptor of the task.
<code>ptr_attr</code>	<code>const MKL_INT</code>	The parameter to change. For details, see the <i>Pointer Attribute</i> column in table "Pointers Supported by the <code>df?EditPtr</code> Task Editor".

Name	Type	Description
<i>ptr</i>	const float* for <code>dfsEditPtr</code> const double* for <code>dfdEditPtr</code>	New pointer. For details, see the <i>Purpose</i> column in table "Pointers Supported by the <code>df?EditPtr</code> Task Editor" .

Output Parameters

Name	Type	Description
<i>status</i>	int	Status of the routine: • <code>DF_STATUS_OK</code> if the routine execution completed successfully. • Non-zero error code otherwise. See "Task Status and Error Reporting" for error code definitions.

Description

The `df?EditPtr` editor replaces the pointer of type *ptr_attr* stored in a Data Fitting task descriptor with a new pointer *ptr*. The table below describes types of pointers supported by the editor:

Pointers Supported by the `df?EditPtr` Task Editor

Pointer Attribute	Purpose
<code>DF_X</code>	Partition <i>x</i> of the interpolation interval, an array of strictly sorted breakpoints
<code>DF_Y</code>	Vector-valued function <i>y</i>
<code>DF_IC</code>	Internal conditions for spline construction. For details, see table "Internal Conditions Supported by Data Fitting Functions" .
<code>DF_BC</code>	Boundary conditions for spline construction. For details, see table "Boundary Conditions Supported by Data Fitting Functions" .
<code>DF_PP_SCOEFF</code>	Spline coefficients

You can use `df?EditPtr` to modify different types of pointers including pointers to the vector-valued function and spline coefficients stored in contiguous memory. Use the `df?EditIdxPtr` editor if you need to modify pointers to coordinates of the vector-valued function or spline coefficients stored at non-contiguous memory locations.

If you modify a partition of the interpolation interval, then you should call the `dfiEditVal` task editor with the corresponding value of `DF_XHINT`, even if the structure of the partition remains the same.

If you pass a `NULL` pointer to the `df?EditPtr` task editor, the task remains unchanged and the routine returns an error code. For the predefined error codes, please see ["Task Status and Error Reporting"](#).

NOTE

You must preserve the arrays *x* (breakpoints), *y* (vector-valued functions), *bc* (boundary conditions), *ic* (internal conditions), and *scoeff* (spline coefficients) through the entire workflow of the Data Fitting computations which use those arrays, as the task stores the addresses of the arrays for spline-based computations.

dfiEditVal

Modifies a parameter value in a Data Fitting task descriptor.

Syntax

```
status = dfiEditVal(task, val_attr, val)
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>task</i>	DFTaskPtr	Descriptor of the task.
<i>val_attr</i>	const MKL_INT	The parameter to change. See table "Parameters Supported by the dfiEditVal Task Editor".
<i>val</i>	const MKL_INT	A new parameter value. See table "Parameters Supported by the dfiEditVal Task Editor".

Output Parameters

Name	Type	Description
<i>status</i>	int	Status of the routine: • DF_STATUS_OK if the routine execution completed successfully. • Non-zero error code otherwise. See "Task Status and Error Reporting" for error code definitions.

Description

The dfiEditVal task editor replaces the parameter of type *val_attr* stored in a Data Fitting task descriptor with a new value *val*. The table below describes valid types of parameter *val_attr* supported by the editor:

Parameters Supported by the dfiEditVal Task Editor

Parameter Attribute	Purpose
DF_NX	Number of breakpoints
DF_XHINT	A flag describing the structure of partition. See table "Hint Values for Partition <i>x</i> " for the list of available values.
DF_NY	Dimension of the vector-valued function
DF_YHINT	A flag describing the structure of the vector-valued function. See table "Hint Values for Vector Function <i>y</i> " for the list of available values.
DF_SPLINE_ORDER	Spline order. See table "Spline Orders Supported by Data Fitting Functions" for the list of available values.

Parameter Attribute	Purpose
DF_SPLINE_TYPE	Spline type. See table "Spline Types Supported by Data Fitting Functions" for the list of available values.
DF_BC_TYPE	Type of boundary conditions used in spline construction. See table "Boundary Conditions Supported by Data Fitting Functions" for the list of available values.
DF_IC_TYPE	Type of internal conditions used in spline construction. See table "Internal Conditions Supported by Data Fitting Functions" for the list of available values.
DF_PP_COEFF_HINT	A flag describing the structure of spline coefficients. See table "Hint Values for Spline Coefficients" for the list of available values.
DF_CHECK_FLAG	A flag which controls checking of Data Fitting parameters. See table "Possible Values for the DF_CHECK_FLAG Parameter" for the list of available values.

If you pass a zero value for the parameter describing the size of the arrays that hold coefficients for a partition, a vector-valued function, or a spline, the parameter held in the Data fitting task remains unchanged and the routine returns an error code. For the predefined error codes, see ["Task Status and Error Reporting"](#).

Possible Values for the DF_CHECK_FLAG Parameter

Value	Description
DF_ENABLE_CHECK_FLAG	Checks the correctness of parameters of Data Fitting computational routines (default mode).
DF_DISABLE_CHECK_FLAG	Disables checking of the correctness of parameters of Data Fitting computational routines.

Use DF_CHECK_FLAG for *val_attr* in order to control validation of parameters of Data Fitting computational routines such as `df?Construct1D`, `df?Interpolate1D`/`df?InterpolateEx1D`, and `df?SearchCells1D`/`df?SearchCellsEx1D`, which can perform better with a small number of interpolation sites or integration limits (fewer than one dozen). The default mode, with checking of parameters enabled, should be used as you develop a Data Fitting-based application. After you complete development you can disable parameter checking in order to improve the performance of your application.

If you modify the parameter describing dimensions of the arrays that hold the vector-valued function or spline coefficients in contiguous memory, you should call the `df?EditPtr` task editor with the corresponding pointers to the vector-valued function or spline coefficients even when this pointer remains unchanged. Call the `df?EditIdxPtr` editor if those arrays are stored in non-contiguous memory locations.

You must call the `dfiEditVal` task editor to edit the structure of the partition DF_XHINT every time you modify a partition using `df?EditPtr`, even if the structure of the partition remains the same.

`df?EditIdxPtr`

Modifies a pointer to the memory representing a coordinate of the data stored in matrix format.

Syntax

```
status = dfsEditIdxPtr(task, ptr_attr, idx, ptr)
```

```
status = dfdEditIdxPtr(task, ptr_attr, idx, ptr)
```

Include Files

- `mkl.h`

Input Parameters

Name	Type	Description
<i>task</i>	DFTaskPtr	Descriptor of the task.
<i>ptr_attr</i>	const MKL_INT	Type of the data to be modified. The parameter takes one of the values described in "Data Attributes Supported by the df?EditIdxPtr Task Editor" .
<i>idx</i>	const MKL_INT	Index of the coordinate whose pointer is to be modified.
<i>ptr</i>	const float* for dfsEditIdxPtr const double* for dfdEditIdxPtr	Pointer to the data that holds values of coordinate <i>idx</i> . For details, see table "Data Attributes Supported by the df?EditIdxPtr Task Editor" .

Output Parameters

Name	Type	Description
<i>status</i>	int	Status of the routine: • <code>DF_STATUS_OK</code> if the routine execution completed successfully. • Non-zero error code otherwise. See "Task Status and Error Reporting" for error code definitions.

Description

The routine modifies a pointer to the array that holds the *idx* coordinate of vector-valued function *y* or the pointer to the array of spline coefficients corresponding to the given coordinate.

You can use the editor if you need to pass into a Data Fitting task or modify the pointer to coordinates of the vector-valued function or spline coefficients held at non-contiguous memory locations. Do not use the editor for coordinates at contiguous memory locations in row-major format.

Before calling this editor, make sure that you have created and initialized the task using a task creation function or a relevant editor such as the generic or specific `df?EditPPSpline1D` editor.

Data Attributes Supported by the df?EditIdxPtr Task Editor

Data Attribute	Description
<code>DF_Y</code>	Vector-valued function <i>y</i>
<code>DF_PP_SCOEFF</code>	Piecewise polynomial spline coefficients

When using `df?EditIdxPtr`, you might receive an error code in the following cases:

- You passed an unsupported parameter value into the editor.
- The value of the index exceeds the predefined value that equals the dimension *ny* of the vector-valued function.
- You pass a `NULL` pointer to the editor. In this case, the task remains unchanged.
- You pass a pointer to the *idx* coordinate of the vector-valued function you provided to contiguous memory in column-major format.

The code example below demonstrates how to use the editor for providing values of a vector-valued function stored in two non-contiguous arrays:

```
#define NX 1000 /* number of break points */
#define NY 2 /* dimension of vector-valued function */
int main()
{
    DFTaskPtr task;
    double x[NX];
    double y1[NX], y2[NX]; /* vector-valued function is stored as two arrays */
    /* Provide first coordinate of two-dimensional function y into creation routine */
    status = dfdNewTask1D( &task, NX, x, DF_NON_UNIFORM_PARTITION, NY, y1,
                          DF_1ST_COORDINATE );
    /* Provide second coordinate of two-dimensional function */
    status = dfdEditIdxPtr(task, DF_Y, 1, y2 );
    ...
}
```

df?QueryPtr

Reads a pointer to an array held in a Data Fitting task descriptor.

Syntax

```
status = dfsQueryPtr(task, ptr_attr, ptr)
```

```
status = dfdQueryPtr(task, ptr_attr, ptr)
```

Include Files

- mkl.h

Input Parameters

Name	Type	Description
<i>task</i>	DFTaskPtr	Descriptor of the task.
<i>ptr_attr</i>	const MKL_INT	The parameter to query. The query routine supports pointer attributes described in the table " Pointers Supported by the df?EditPtr Task Editor ". For details, see the <i>Pointer Attribute</i> column in the table.

Output Parameters

Name	Type	Description
<i>ptr</i>	float** for dfsQueryPtr double** for dfdQueryPtr	Pointer to array returned by the query routine. For details, see the <i>Purpose</i> column in table " Pointers Supported by the df?EditPtr Task Editor ".
<i>status</i>	int	Status of the routine: • DF_STATUS_OK if the routine execution completed successfully. • Non-zero error code otherwise. See "Task Status and Error Reporting" for error code definitions.

Description

The `df?QueryPtr` routine returns the pointer of type `ptr_attr` stored in a Data Fitting task descriptor as parameter `ptr`. Attributes of the pointers supported by the query function are identical to those supported by the editor `df?EditPtr` editor in the table "[Pointers Supported by the df?EditPtr Task Editor](#)".

You can use `df?QueryPtr` to read different types of pointers including pointers to the vector-valued function and spline coefficients stored in contiguous memory.

dfiQueryVal

Reads a parameter value in a Data Fitting task descriptor.

Syntax

```
status = dfiQueryVal(task, val_attr, val)
```

Include Files

- `mkl.h`

Input Parameters

Name	Type	Description
<code>task</code>	<code>DFTaskPtr</code>	Descriptor of the task.
<code>val_attr</code>	<code>const MKL_INT</code>	The parameter to query. The query function supports the parameter attributes described in " Parameters Supported by the dfiEditVal Task Editor ".

Output Parameters

Name	Type	Description
<code>val</code>	<code>MKL_INT</code>	The parameter value returned by the query function. See table " Parameters Supported by the dfiEditVal Task Editor ".
<code>status</code>	<code>int</code>	Status of the routine: • <code>DF_STATUS_OK</code> if the routine execution completed successfully. • Non-zero error code otherwise. See "Task Status and Error Reporting" for error code definitions.

Description

The `dfiQueryVal` routine returns a parameter of type `val_attr` stored in a Data Fitting task descriptor as parameter `val`. The query function supports the parameter attributes described in "[Parameters Supported by the dfiEditVal Task Editor](#)".

df?QueryIdxPtr

Reads a pointer to the memory representing a coordinate of the data stored in matrix format.

Syntax

```
status = dfsQueryIdxPtr(task, ptr_attr, idx, ptr)
```

```
status = dfdQueryIdxPtr(task, ptr_attr, idx, ptr)
```

Include Files

- `mkl.h`

Input Parameters

Name	Type	Description
<code>task</code>	<code>DFTaskPtr</code>	Descriptor of the task.
<code>ptr_attr</code>	<code>const MKL_INT</code>	Pointer attribute to query. The parameter takes one of the attributes described in "Data Attributes Supported by the df?EditIdxPtr Task Editor" .
<code>idx</code>	<code>const MKL_INT</code>	Index of the coordinate of the pointer to query.

Output Parameters

Name	Type	Description
<code>ptr</code>	<code>float*</code> for <code>dfsQueryIdxPtr</code> <code>double*</code> for <code>dfdQueryIdxPtr</code>	Pointer to the data that holds values of coordinate <code>idx</code> returned. For details, see table "Data Attributes Supported by the df?EditIdxPtr Task Editor" .
<code>status</code>	<code>int</code>	Status of the routine: • <code>DF_STATUS_OK</code> if the routine execution completed successfully. • Non-zero error code otherwise. See "Task Status and Error Reporting" for error code definitions.

Description

The routine returns a pointer to the array that holds the `idx` coordinate of vector-valued function `y` or the pointer to the array of spline coefficients corresponding to the given coordinate.

You can use the query routine if you need the pointer to coordinates of the vector-valued function or spline coefficients held at non-contiguous memory locations or at a contiguous memory location in row-major format (the default storage format for spline coefficients).

Before calling this query routine, make sure that you have created and initialized the task using a task creation function or a relevant editor such as the generic or specific `df?EditPPSpline1D` editor.

When using `df?QueryIdxPtr`, you might receive an error code in the following cases:

- You passed an unsupported parameter value into the editor.
- The value of the index exceeds the predefined value that equals the dimension `ny` of the vector-valued function.
- You request the pointer to the `idx` coordinate of the vector-valued function you provided to contiguous memory in column-major format.

Computational Routines

Data Fitting computational routines are functions used to perform spline-based computations, such as:

- spline construction
- computation of values, derivatives, and integrals of the predefined order
- cell search

Once you create a Data Fitting task and initialize the required parameters, you can call computational routines as many times as necessary.

The table below lists the available computational routines:

Data Fitting Computational Routines

Routine	Description
df?Construct1D	Constructs a spline for a one-dimensional Data Fitting task.
df?Interpolate1D	Computes spline values and derivatives.
df?InterpolateEx1D	Computes spline values and derivatives by calling user-provided interpolants.
df?Integrate1D	Computes spline-based integrals.
df?IntegrateEx1D	Computes spline-based integrals by calling user-provided integrators.
df?SearchCells1D	Finds indices of cells containing interpolation sites.
df?SearchCellsEx1D	Finds indices of cells containing interpolation sites by calling user-provided cell searchers.

If a Data Fitting computation completes successfully, the computational routines return the `DF_STATUS_OK` code. If an error occurs, the routines return an error code specifying the origin of the failure. Some possible errors are the following:

- The task pointer is `NULL`.
- Memory allocation failed.
- The computation failed for another reason.

For the list of available status codes, see ["Task Status and Error Reporting"](#).

NOTE

Data Fitting computational routines do not control errors for floating-point conditions, such as overflow, gradual underflow, or operations with Not a Number (NaN) values.

[df?Construct1D](#)

Syntax

Constructs a spline of the given type.

```
status = dfsConstruct1D(task, s_format, method)
```

```
status = dfdConstruct1D(task, s_format, method)
```

Include Files

- `mk1.h`

Input Parameters

Name	Type	Description
<i>task</i>	DFTaskPtr	Descriptor of the task.
<i>s_format</i>	const MKL_INT	Spline format. The supported value is DF_PP_SPLINE.
<i>method</i>	const MKL_INT	Construction method. The supported value is DF_METHOD_STD.

Output Parameters

Name	Type	Description
<i>status</i>	int	Status of the routine: - DF_STATUS_OK if the routine execution completed successfully. - Non-zero error code if the routine execution failed. See "Task Status and Error Reporting" for error code definitions.

Description

Before calling `df?Construct1D`, you need to create and initialize the task, and set the parameters representing the spline. Then you can call the `df?Construct1D` routine to construct the spline. The format of the spline is defined by parameter *s_format*. The method for spline construction is defined by parameter *method*. Upon successful construction, the spline coefficients are available in the user-provided memory location in the format you set through the Data Fitting editor. For the available storage formats, see table ["Hint Values for Spline Coefficients"](#).

`df?Interpolate1D/df?InterpolateEx1D`

Runs data fitting computations.

Syntax

```
status = dfsInterpolate1D(task, type, method, nsite, site, sitehint, ndorder, dorder,
datahint, r, rhint, cell)
```

```
status = dfdInterpolate1D(task, type, method, nsite, site, sitehint, ndorder, dorder,
datahint, r, rhint, cell)
```

```
status = dfsInterpolateEx1D(task, type, method, nsite, site, sitehint, ndorder,
dorder, datahint, r, rhint, cell, le_cb, le_params, re_cb, re_params, i_cb, i_params,
search_cb, search_params)
```

```
status = dfdInterpolateEx1D(task, type, method, nsite, site, sitehint, ndorder,
dorder, datahint, r, rhint, cell, le_cb, le_params, re_cb, re_params, i_cb, i_params,
search_cb, search_params)
```

Include Files

- `mk1.h`

Input Parameters

Name	Type	Description
<i>task</i>	DFTaskPtr	Descriptor of the task.
<i>type</i>	const MKL_INT	Type of spline-based computations. The parameter takes one or more values combined with an OR operation. For the list of possible values, see table "Computation Types Supported by the df?Interpolate1D/ df?Interpolate1D Routines" .
<i>method</i>	const MKL_INT	Computation method. The supported value is DF_METHOD_PP.
<i>nsite</i>	const MKL_INT	Number of interpolation sites.
<i>site</i>	const float* for dfsInterpolate1D/ dfsInterpolateEx1D const double* for dfdInterpolate1D/ dfdInterpolateEx1D	Array of interpolation sites of size <i>nsite</i> . The structure of the array is defined by the <i>sitehint</i> parameter: • If sites form a non-uniform partition, the array should contain <i>nsite</i> values. • If sites form a uniform partition, the array should contain two entries that represent the left and the right interpolation sites. The first entry of the array contains the left-most interpolation point. The second entry of the array contains the right-most interpolation point.
<i>sitehint</i>	const MKL_INT	A flag describing the structure of the interpolation sites. For the list of possible values of <i>sitehint</i> , see table "Hint Values for Interpolation Sites" . If you set the flag to DF_NO_HINT, the library interprets the site-defined partition as non-uniform.
<i>ndorder</i>	const MKL_INT	Maximal derivative order increased by one to be computed at interpolation sites.
<i>dorder</i>	const MKL_INT*	Array of size <i>ndorder</i> that defines the order of the derivatives to be computed at the interpolation sites. If all the elements in <i>dorder</i> are zero, the library computes the spline values only. If you do not need interpolation computations, set <i>ndorder</i> to zero and pass a NULL pointer to <i>dorder</i> .
<i>datahint</i>	const float* for dfsInterpolate1D/ dfsInterpolateEx1D const double* for dfdInterpolate1D/ dfdInterpolateEx1D	Array that contains additional information about the structure of partition <i>x</i> and interpolation sites. This data helps to speed up the computation. If you provide a NULL pointer, the routine uses the default settings for computations. For details on the <i>datahint</i> array, see table "Structure of the datahint Array" .
<i>r</i>	float* for dfsInterpolate1D/ dfsInterpolateEx1D	Array for results. If you do not need spline-based interpolation or integration, set this pointer to NULL.

Name	Type	Description
	double* for dfdInterpolate1D/ dfdInterpolateEx1D	
<i>rhint</i>	const MKL_INT	A flag describing the structure of the results. For the list of possible values of <i>rhint</i> , see table " Hint Values for the rhint Parameter ". If you set the flag to DF_NO_HINT, the library stores the result in row-major format.
<i>cell</i>	MKL_INT*	Array of cell indices in partition <i>x</i> that contain the interpolation sites. Provide this parameter as input if <i>type</i> is DF_INTERP_USER_CELL. If you do not need cell indices, set this parameter to NULL.
<i>le_cb</i>	constdfsInterpCallBack for dfsInterpolateEx1D constdfdInterpCallBack for dfdInterpolateEx1D	User-defined callback function for extrapolation at the sites to the left of the interpolation interval. Set to NULL if you are not supplying a callback function.
<i>le_params</i>	const void*	Pointer to additional user-defined parameters passed by the library to the <i>le_cb</i> function. Set to NULL if there are no additional parameters or if you are not supplying a callback function.
<i>re_cb</i>	constdfsInterpCallBack for dfsInterpolateEx1D constdfdInterpCallBack for dfdInterpolateEx1D	User-defined callback function for extrapolation at the sites to the right of the interpolation interval. Set to NULL if you are not supplying a callback function.
<i>re_params</i>	const void*	Pointer to additional user-defined parameters passed by the library to the <i>re_cb</i> function. Set to NULL if there are no additional parameters or if you are not supplying a callback function.
<i>i_cb</i>	constdfsInterpCallBack for dfsInterpolateEx1D constdfdInterpCallBack for dfdInterpolateEx1D	User-defined callback function for interpolation within the interpolation interval. Set to NULL if you are not supplying a callback function.
<i>i_params</i>	const void*	Pointer to additional user-defined parameters passed by the library to the <i>i_cb</i> function. Set to NULL if there are no additional parameters or if you are not supplying a callback function.
<i>search_cb</i>	constdfsSearchCellsCal lBack for dfsInterpolateEx1D constdfdSearchCellsCal lBack for dfdInterpolateEx1D	User-defined callback function for computing indices of cells that can contain interpolation sites. Set to NULL if you are not supplying a callback function.

Name	Type	Description
<i>search_params</i>	const void*	Pointer to additional user-defined parameters passed by the library to the <i>search_cb</i> function. Set to NULL if there are no additional parameters or if you are not supplying a callback function.

Output Parameters

Name	Type	Description
<i>status</i>	int	Status of the routine: - DF_STATUS_OK if the routine execution completed successfully. - Non-zero error code if the routine execution failed. See "Task Status and Error Reporting" for error code definitions.
<i>r</i>		Contains results of computations at the interpolation sites.
<i>cell</i>		Array of cell indices in partition <i>x</i> that contain the interpolation sites, which is computed if <i>type</i> is DF_CELL.

Description

The `df?Interpolate1D/df?InterpolateEx1D` routine performs spline-based computations with user-defined settings. The routine supports two types of computations for interpolation sites provided in array *site*:

Computation Types Supported by the `df?Interpolate1D/df?InterpolateEx1D` Routines

Type	Description
DF_INTERP	Compute derivatives of predefined order. The derivative of the zero order is the spline value.
DF_INTERP_USER_CELL	Compute derivatives of predefined order given user-provided cell indices. The derivative of the zero order is the spline value. For this type of the computations you should provide a valid <i>cell</i> array, which holds the indices of cells in the <i>site</i> array containing relevant interpolation sites.
DF_CELL	Compute indices of cells in partition <i>x</i> that contain the sites.

If the indices of cells which contain interpolation types are available before the call to `df?Interpolate1D/df?InterpolateEx1D`, you can improve performance by using the `DF_INTERP_USER_CELL` computation type.

NOTE

If you pass any combination of `DF_INTERP`, `DF_INTERP_USER_CELL`, and `DF_CELL` computation types to the routine, the library uses the `DF_INTERP_USER_CELL` computation mode.

If you specify `DF_INTERP_USER_CELL` computation mode and a user-defined callback function for computing cell indices to `df?InterpolateEx1D`, the library uses the `DF_INTERP_USER_CELL` computation mode, and the call-back function is not called.

If the sites do not belong to interpolation interval $[a, b]$, the library uses:

- polynomial P_0 of the spline constructed on interval $[x_0, x_1]$ for computations at the sites to the left of a .
- polynomial P_{n-2} of the spline constructed on interval $[x_{n-2}, x_{n-1}]$ for computations at the sites to the right of b .

Interpolation sites support the following hints:

Hint Values for Interpolation Sites

Value	Description
<code>DF_NON_UNIFORM_PARTITION</code>	Partition is non-uniform.
<code>DF_UNIFORM_PARTITION</code>	Partition is uniform.
<code>DF_SORTED_DATA</code>	Interpolation sites are sorted in the ascending order and define a non-uniform partition.
<code>DF_NO_HINT</code>	No hint is provided. By default, the partition defined by interpolation sites is interpreted as non-uniform.

NOTE

If you pass a sorted array of interpolation sites to the Intel MKL, set the `sitehint` parameter to the `DF_SORTED_DATA` value. The library uses this information when choosing the search algorithm and ignores any other data hints about the structure of the interpolation sites.

Data Fitting computation routines can use the following hints to speed up the computation:

- `DF_UNIFORM_PARTITION` describes the structure of breakpoints and the interpolation sites.
- `DF_QUASI_UNIFORM_PARTITION` describes the structure of breakpoints.

Pass the above hints to the library when appropriate.

The x pointer defines the memory location for the sets of interpolation and integration results for all coordinates of function y . The sets are stored one by one, in the successive order of the function coordinates from y_1 to y_{ny} .

You can define the following settings for packing the results within each set:

- Computation type: interpolation, integration, or both.
- Computation parameters: derivative orders.
- Storage format for the results. You can specify the format using the `rhint` parameter values described in the table below:

Hint Values for the `rhint` Parameter

Value	Description
<code>DF_MATRIX_STORAGE_ROWS</code>	Data is stored in row-major format according to C conventions.
<code>DF_MATRIX_STORAGE_COLS</code>	Data is stored in column-major format according to Fortran conventions.

Value	Description
DF_NO_HINT	No hint is provided. By default, the results are stored in row-major format.

For spline-based interpolation, you should set the derivatives whose values are required for the computation. You can provide the derivatives by setting the *dorder* array of size *ndorder* as follows:

$$dorder[i] = \begin{cases} 1, & \text{if derivative of the } i\text{-th order is required} \\ 0, & \text{otherwise} \end{cases} \quad i = 0, \dots, ndorder - 1$$

See below a common structure of the storage formats of the interpolation results within each set *r* for computing derivatives of order $i_1, i_2, \dots, i_m$ at *nsite* interpolation sites. In this description, *j* is the coordinate of the vector-valued function:

- Row-major format

$r_j(i_1, 0)$	$r_j(i_2, 0)$	...	$r_j(i_m, 0)$
$r_j(i_1, 1)$	$r_j(i_2, 1)$	...	$r_j(i_m, 1)$
...	...	...	...
$r_j(i_1, nsite - 1)$	$r_j(i_2, nsite - 1)$	...	$r_j(i_m, nsite - 1)$

- Column-major format

$r_j(i_1, 0)$	$r_j(i_1, 1)$	...	$r_j(i_1, nsite - 1)$
$r_j(i_2, 0)$	$r_j(i_2, 1)$	...	$r_j(i_2, nsite - 1)$
...	...	...	...
$r_j(i_m, 0)$	$r_j(i_m, 1)$	...	$r_j(i_m, nsite - 1)$

To speed up Data Fitting computations, use the *datahint* parameter that provides additional information about the structure of the partition and interpolation sites. This data represents a floating-point or a double array with the following structure:

Structure of the *datahint* Array

Element Number	Description
0	Task dimension
1	Type of additional information
2	Reserved field
3	The total number <i>q</i> of elements containing additional information.
4	Element (1)
...	...
<i>q</i> +3	Element (<i>q</i>)

Data Fitting computation functions support the following types of additional information for *datahint*[1]:

Types of Additional Information

Type	Element Number	Parameter
DF_NO_APRIORI_INFO	0	No parameters are provided. Information about the data structure is absent.
DF_APRIORI_MOST_LIKELY_CELL	1	Index of the cell that is likely to contain interpolation sites.

To compute indices of the cells that contain interpolation sites, provide the pointer to the array of size *nsite* for the results. The library supports the following scheme of cell indexing for the given partition $\{x_i\}$, $i=1,\dots,nx$:

$$cell[j] = i, \text{ if } site[j] \in [x_i, x_{i+1}), i = 0, \dots, nx,$$

where

- $x_0 = -\infty$
- $x_{nx+1} = +\infty$
- $j = 0, \dots, nsite-1$

To perform interpolation computations with spline types unsupported in the Data Fitting component, use the extended version of the routine `df?InterpolateEx1D`. With this routine, you can provide user-defined callback functions for computations within, to the left of, or to the right of interpolaton interval $[a, b]$. The callback functions compute indices of the cells that contain the specified interpolation sites or can serve as an approximation for computing the exact indices of such cells.

If you do not pass any function for computations at the sites outside the interval $[a, b]$, the routine uses the default settings.

df?Integrate1D/df?IntegrateEx1D

Computes a spline-based integral.

Syntax

```
status = dfsIntegrate1D(task, method, nlim, llim, llimhint, rlim, rlimhint, ldatahint,
rdatahint, r, rhint)
```

```
status = dfdIntegrate1D(task, method, nlim, llim, llimhint, rlim, rlimhint, ldatahint,
rdatahint, r, rhint)
```

```
status = dfsIntegrateEx1D(task, method, nlim, llim, llimhint, rlim, rlimhint,
ldatahint, rdatahint, r, rhint, le_cb, le_params, re_cb, re_params, i_cb, i_params,
search_cb, search_params)
```

```
status = dfdIntegrateEx1D(task, method, nlim, llim, llimhint, rlim, rlimhint,
ldatahint, rdatahint, r, rhint, le_cb, le_params, re_cb, re_params, i_cb, i_params,
search_cb, search_params)
```

Include Files

- `mk1.h`

Input Parameters

Name	Type	Description
<i>task</i>	DFTaskPtr	Descriptor of the task.
<i>method</i>	const MKL_INT	Integration method. The supported value is <code>DF_METHOD_PP</code> .
<i>nlim</i>	const MKL_INT	Number of pairs of integration limits.
<i>llim</i>	const float* for dfsIntegrate1D/ dfsIntegrateEx1D const double* for dfdIntegrate1D/ dfdIntegrateEx1D	Array of size <i>nlim</i> that defines the left-side integration limits.
<i>llimhint</i>	const MKL_INT	A flag describing the structure of the left-side integration limits <i>llim</i> . For the list of possible values of <i>llimhint</i> , see table "Hint Values for Integration Limits" . If you set the flag to the <code>DF_NO_HINT</code> value, the library assumes that the left-side integration limits define a non-uniform partition.
<i>rlim</i>	const float* for dfsIntegrate1D/ dfsIntegrateEx1D const double* for dfdIntegrate1D/ dfdIntegrateEx1D	Array of size <i>nlim</i> that defines the right-side integration limits.
<i>rlimhint</i>	const MKL_INT	A flag describing the structure of the right-side integration limits <i>rlim</i> . For the list of possible values of <i>rlimhint</i> , see table "Hint Values for Integration Limits" . If you set the flag to the <code>DF_NO_HINT</code> value, the library assumes that the right-side integration limits define a non-uniform partition.
<i>ldatahint</i>	const float* for dfsIntegrate1D/ dfsIntegrateEx1D const double* for dfdIntegrate1D/ dfdIntegrateEx1D	Array that contains additional information about the structure of partition <i>x</i> and left-side integration limits. For details on the <i>ldatahint</i> array, see table "Structure of the datahint Array" in the description of the <code>df?</code> Interpolate1D function.
<i>rdatahint</i>	const float* for dfsIntegrate1D/ dfsIntegrateEx1D const double* for dfdIntegrate1D/ dfdIntegrateEx1D	Array that contains additional information about the structure of partition <i>x</i> and right-side integration limits. For details on the <i>rdatahint</i> array, see table "Structure of the datahint Array" in the description of the <code>df?</code> Interpolate1D function.
<i>rhint</i>	const MKL_INT	A flag describing the structure of the results. For the list of possible values of <i>rhint</i> , see table "Hint Values for Integration Results" . If you set the flag to the <code>DF_NO_HINT</code> value, the library stores the results in row-major format.

Name	Type	Description
<i>le_cb</i>	constdfsIntegrCallBack for dfsIntegrateEx1D constdfdIntegrCallBack for dfdIntegrateEx1D	User-defined callback function for integration on interval $[llim[i], \min(rlim[i], a))$ for $llim[i] < a$. Set to NULL if you are not supplying a callback function.
<i>le_params</i>	const void*	Pointer to additional user-defined parameters passed by the library to the <i>le_cb</i> function. Set to NULL if there are no additional parameters or if you are not supplying a callback function.
<i>re_cb</i>	constdfsInterpCallBack for dfsIntegrateEx1D constdfdInterpCallBack for dfdIntegrateEx1D	User-defined callback function for integration on interval $[\max(llim[i], b), rlim[i])$ for $rlim[i] \geq b$. Set to NULL if you are not supplying a callback function.
<i>re_params</i>	const void*	Pointer to additional user-defined parameters passed by the library to the <i>re_cb</i> function. Set to NULL if there are no additional parameters or if you are not supplying a callback function.
<i>i_cb</i>	constdfsIntegrCallBack for dfsIntegrateEx1D constdfdIntegrCallBack for dfdIntegrateEx1D	User-defined callback function for integration on interval $[\max(a, llim[i],), \min(rlim[i], b))$. Set to NULL if you are not supplying a callback function.
<i>i_params</i>	const void*	Pointer to additional user-defined parameters passed by the library to the <i>i_cb</i> function. Set to NULL if there are no additional parameters or if you are not supplying a callback function.
<i>search_cb</i>	constdfsSearchCellsCal lBack for dfsIntegrateEx1D constdfdSearchCellsCal lBack for dfdIntegrateEx1D	User-defined callback function for computing indices of cells that can contain interpolation sites. Set to NULL if you are not supplying a callback function.
<i>search_params</i>	const void*	Pointer to additional user-defined parameters passed by the library to the <i>search_cb</i> function. Set to NULL if there are no additional parameters or if you are not supplying a callback function.

Output Parameters

Name	Type	Description
<i>status</i>	int	Status of the routine: DF_STATUS_OK if the routine execution completed successfully.

Name	Type	Description
		Non-zero error code if the routine execution failed. See "Task Status and Error Reporting" for error code definitions.
r	float* for dfsIntegrate1D/ dfsIntegrateEx1D double* for dfdIntegrate1D/ dfdIntegrateEx1D	Array of integration results. The size of the array should be sufficient to hold $nlim*ny$ values, where ny is the dimension of the vector-valued function. The integration results are packed according to the settings in $rhint$.

Description

The `df?Integrate1D/df?IntegrateEx1D` routine computes spline-based integral on user-defined intervals

$$I(i, j) = \int_{rl_i}^{ll_i} f_j(x) dx,$$

where $rl_i = rlim[i]$, $ll_i = llim[i]$, and $i = 0, \dots, ny - 1$.

If $rlim[i] < llim[i]$, the routine returns

$$I(i, j) = -\int_{ll_i}^{rl_i} f_j(x) dx$$

The routine supports the following hint values for integration results:

Hint Values for Integration Results

Value	Description
DF_MATRIX_STORAGE_ROWS	Data is stored in row-major format according to C conventions.
DF_MATRIX_STORAGE_COLS	Data is stored in column-major format according to Fortran conventions.
DF_NO_HINT	No hint is provided. By default, the coordinates of vector-valued function y are provided and stored in row-major format.

A common structure of the storage formats for the integration results is as follows:

- Row-major format

$I(0, 0)$	...	$I(0, nlim - 1)$
...	...	...
$I(ny - 1, 0)$	...	$I(ny - 1, nlim - 1)$

- Column-major format

$I(0, 0)$	...	$I(ny - 1, 0)$
...	...	...
$I(0, nlim - 1)$	...	$I(ny - 1, nlim - 1)$

Using the `llimhint` and `rlimhint` parameters, you can provide the following hint values for integration limits:

Hint Values for Integration Limits

Value	Description
DF_SORTED_DATA	Integration limits are sorted in the ascending order and define a non-uniform partition.
DF_NON_UNIFORM_PARTITION	Partition defined by integration limits is non-uniform.
DF_UNIFORM_PARTITION	Partition defined by integration limits is uniform.
DF_NO_HINT	No hint is provided. By default, partition defined by integration limits is interpreted as non-uniform.

To compute integration with splines unsupported in the Data Fitting component, use the extended version of the routine `df?IntegrateEx1D`. With this routine, you can provide user-defined callback functions that compute:

- integrals within, to the left of, or to the right of the interpolation interval $[a, b]$
- indices of cells that contain the provided integration limits or can serve as an approximation for computing the exact indices of such cells

If you do not pass callback functions, the routine uses the default settings.

Input Parameters

Name	Type	Description
<code>task</code>	<code>DFTaskPtr</code>	Descriptor of the task.
<code>method</code>	<code>const MKL_INT</code>	Search method. The supported value is <code>DF_METHOD_STD</code> .
<code>nsite</code>	<code>const MKL_INT*</code>	Number of interpolation sites.

Name	Type	Description
<i>site</i>	const float* for dfsSearchCells1D/ dfsSearchCellsEx1D const double* for dfdSearchCells1D/ dfdSearchCellsEx1D	Array of interpolation sites of size <i>nsite</i>. The structure of the array is defined by the <i>sit hint</i> parameter: • If the sites form a non-uniform partition, the array should contain <i>nsite</i> values. • If the sites form a uniform partition, the array should contain two entries that represent the left-most and the right-most interpolation sites. The first entry of the array contains the left-most interpolation point. The second entry of the array contains the right-most interpolation point.
<i>sit hint</i>	const MKL_INT	A flag describing the structure of the interpolation sites. For the list of possible values of <i>sit hint</i>, see table "Hint Values for Interpolation Sites". If you set the flag to <code>DF_NO_HINT</code>, the library interprets the site-defined partition as non-uniform.
<i>data hint</i>	const float* for dfsSearchCells1D/ dfsSearchCellsEx1D const double* for dfdSearchCells1D/ dfdSearchCellsEx1D	Array that contains additional information about the structure of the partition and interpolation sites. This data helps to speed up the computation. If you provide a <code>NULL</code> pointer, the routine uses the default settings for computations. For details on the <i>data hint</i> array, see table "Structure of the data hint Array".
<i>search_cb</i>	constdfsSearchCellsCallBac k for dfsSearchCellsEx1D constdfdSearchCellsCallBac k for dfdSearchCellsEx1D	User-defined callback function for computing indices of cells that can contain interpolation sites. Set to <code>NULL</code> if you are not supplying a callback function.
<i>search_pa rams</i>	const void*	Pointer to additional user-defined parameters passed by the library to the <i>search_cb</i> function. Set to <code>NULL</code> if there are no additional parameters or if you are not supplying a callback function.

Output Parameters

Name	Type	Description
<i>status</i>	int	Status of the routine: • <code>DF_STATUS_OK</code> if the routine execution completed successfully. • Non-zero error code if the routine execution failed. See "Task Status and Error Reporting" for error code definitions.
<i>cell</i>	MKL_INT*	Array of cell indices in the partition that contain the interpolation sites.

Description

The `df?SearchCells1D/df?SearchCellsEx1D` routines return array *cell* of indices of sub-intervals (cells) in the partition that contain interpolation sites available in array *site*. For details on the cell indexing scheme, see the description of the `df?Interpolate1D/df?InterpolateEx1D` computation routines.

Use the *datahint* parameter to provide additional information about the structure of the partition and/or interpolation sites. The definition of the *datahint* parameter is available in the description of the `df?Interpolate1D/df?InterpolateEx1D` computation routines.

For description of the user-defined callback for computation of cell indices, see `df?SearchCellsCallBack`.

df?InterpCallBack

A callback function for user-defined interpolation to be passed into `df?InterpolateEx1D`.

Syntax

```
status = dfsInterpCallBack(n, cell, site, r, params)
```

```
status = dfdInterpCallBack(n, cell, site, r, params)
```

Include Files

- `mk1.h`

Input Parameters

Name	Type	Description
<i>n</i>	long long*	Number of interpolation sites.
<i>cell</i>	long long*	Array of size <i>n</i> containing indices of the cells to which the interpolation sites in array <i>site</i> belong.
<i>site</i>	float* for <code>dfsInterpCallBack</code> double* for <code>dfdInterpCallBack</code>	Array of interpolation sites of size <i>n</i> .
<i>params</i>	void*	Pointer to user-defined parameters of the callback function.

Output Parameters

Name	Type	Description
<i>status</i>	int	The status returned by the callback function: • Zero indicates successful completion of the callback operation. • A negative value indicates an error. • A positive value indicates a warning.

Name	Type	Description
		See "Task Status and Error Reporting" for error code definitions.
<i>r</i>	float* for dfsInterpCallback double* for dfdInterpCallback	Array of the computed interpolation results packed in row-major format.

Description

When passed into the `df?InterpolateEx1D` routine, this function performs user-defined interpolation operation.

df?IntegrCallback

A callback function that you can pass into `df?IntegrateEx1D` to define integration computations.

Syntax

```
status = dfsIntegrCallback(n, lcell, llim, rcell, rlim, r, params)
```

```
status = dfdIntegrCallback(n, lcell, llim, rcell, rlim, r, params)
```

Include Files

- `mkl.h`

Input Parameters

Name	Type	Description
<i>n</i>	long long*	Number of pairs of integration limits.
<i>lcell</i>	long long*	Array of size <i>n</i> with indices of the cells that contain the left-side integration limits in array <i>llim</i> .
<i>llim</i>	float* for dfsIntegrCallback double* for dfdIntegrCallback	Array of size <i>n</i> that holds the left-side integration limits.
<i>rcell</i>	long long*	Array of size <i>n</i> with indices of the cells that contain the right-side integration limits in array <i>rlim</i> .
<i>rlim</i>	float* for dfsIntegrCallback double* for dfdIntegrCallback	Array of size <i>n</i> that holds the right-side integration limits.
<i>params</i>	void*	Pointer to user-defined parameters of the callback function.

Output Parameters

Name	Type	Description
<i>status</i>	int	The status returned by the callback function: • Zero indicates successful completion of the callback operation. • A negative value indicates an error. • A positive value indicates a warning. See "Task Status and Error Reporting" for error code definitions.
<i>r</i>	float* for <code>dfsIntegrCallback</code> double* for <code>dfdIntegrCallback</code>	Array of integration results. For packing the results in row-major format, follow the instructions described in df?Interpolate1D/df?InterpolateEx1D.

Description

When passed into the `df?IntegrateEx1D` routine, this function defines integration computations. If at least one of the integration limits is outside the interpolation interval $[a, b]$, the library decomposes the integration into sub-intervals that belong to the extrapolation range to the left of a , the extrapolation range to the right of b , and the interpolation interval $[a, b]$, as follows:

- If the left integration limit is to the left of the interpolation interval ($llim < a$), the `df?IntegrateEx1D` routine passes `llim` as the left integration limit and `min(rlim, a)` as the right integration limit to the user-defined callback function.
- If the right integration limit is to the right of the interpolation interval ($rlim > b$), the `df?IntegrateEx1D` routine passes `max(llim, b)` as the left integration limit and `rlim` as the right integration limit to the user-defined callback function.
- If the left and the right integration limits belong to the interpolation interval, the `df?IntegrateEx1D` routine passes them to the user-defined callback function unchanged.

The value of the integral is the sum of integral values obtained on the sub-intervals.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

df?SearchCellsCallBack

A callback function for user-defined search to be passed into `df?InterpolateEx1D` or `df?SearchCellsEx1D`.

Syntax

```
status = dfsSearchCellsCallBack(n, site, cell, flag, params)
status = dfdSearchCellsCallBack(n, site, cell, flag, params)
```

Include Files

- `mkl.h`

Input Parameters

Name	Type	Description
<i>n</i>	long long*	Number of interpolation sites.
<i>site</i>	float* for dfsSearchCellsCallBack double* for dfdSearchCellsCallBack	Array of interpolation sites of size <i>n</i> .
<i>flag</i>	int*	Array of size <i>n</i> , with values set as follows: • If the cell with index <i>cell[i]</i> contains <i>site[i]</i>, set <i>flag[i]</i> to 1. • Otherwise, set <i>flag[i]</i> to zero. In this case, the library interprets the index as an approximation and computes the index of the cell containing <i>site[i]</i> by using the provided index as a starting point for the search.
<i>params</i>	void*	Pointer to user-defined parameters of the callback function.

Output Parameters

Name	Type	Description
<i>status</i>	int	The status returned by the callback function: • Zero indicates successful completion of the callback operation. • A negative value indicates an error. • The <code>DF_STATUS_EXACT_RESULT</code> status indicates that cell indices returned by the callback function are exact. In this case, you do not need to initialize entries of the <i>flag</i> array. • A positive value indicates a warning. See "Task Status and Error Reporting" for error code definitions.

Name	Type	Description
<i>cell</i>	long long*	Array of size n that returns indices of the cells computed by the callback function.

Description

When passed into the `df?InterpolateEx1D` or `df?SearchCellsEx1D` routine, this function performs a user-defined search.

Task Destructors

Task destructors are routines used to delete task descriptors and deallocate the corresponding memory resources. The Data Fitting task destructor `dfDeleteTask` destroys a Data Fitting task and frees the memory.

`dfDeleteTask`

Destroys a Data Fitting task object and frees the memory.

Syntax

```
status = dfDeleteTask(&task)
```

Include Files

- `mk1.h`

Input Parameters

Name	Type	Description
<i>task</i>	DFTaskPtr	Descriptor of the task to destroy.

Output Parameters

Name	Type	Description
<i>status</i>	int	Status of the routine: • <code>DF_STATUS_OK</code> if the task is deleted successfully. • Non-zero error code if the operation failed. See "Task Status and Error Reporting" for error code definitions.

Description

Given a pointer to a task descriptor, this routine deletes the Data Fitting task descriptor and frees the memory allocated for the structure. If the task is deleted successfully, the routine sets the task pointer to `NULL`. Otherwise, the routine returns an error code.

Linear Solvers Basics

Many applications in science and engineering require the solution of a system of linear equations. This problem is usually expressed mathematically by the matrix-vector equation, $Ax = b$, where A is an m -by- n matrix, x is the n element column vector and b is the m element column vector. The matrix A is usually referred to as the coefficient matrix, and the vectors x and b are referred to as the solution vector and the right-hand side, respectively.

Basic concepts related to solving linear systems with sparse matrices are described in [Sparse Linear Systems](#) and various storage schemes for sparse matrices are described in [Sparse Matrix Storage Formats](#).

Sparse Linear Systems

In many real-life applications, most of the elements in A are zero. Such a matrix is referred to as sparse. Conversely, matrices with very few zero elements are called dense. For sparse matrices, computing the solution to the equation $Ax = b$ can be made much more efficient with respect to both storage and computation time, if the sparsity of the matrix can be exploited. The more an algorithm can exploit the sparsity without sacrificing the correctness, the better the algorithm.

Generally speaking, computer software that finds solutions to systems of linear equations is called a solver. A solver designed to work specifically on sparse systems of equations is called a sparse solver. Solvers are usually classified into two groups - direct and iterative.

Iterative Solvers start with an initial approximation to a solution and attempt to estimate the difference between the approximation and the true result. Based on the difference, an iterative solver calculates a new approximation that is closer to the true result than the initial approximation. This process is repeated until the difference between the approximation and the true result is sufficiently small. The main drawback to iterative solvers is that the rate of convergence depends greatly on the values in the matrix A . Consequently, it is not possible to predict how long it will take for an iterative solver to produce a solution. In fact, for ill-conditioned matrices, the iterative process will not converge to a solution at all. However, for well-conditioned matrices it is possible for iterative solvers to converge to a solution very quickly. Consequently, if an application involves well-conditioned matrices iterative solvers can be very efficient.

Direct Solvers, on the other hand, factor the matrix A into the product of two triangular matrices and then perform a forward and backward triangular solve.

This approach makes the time required to solve a systems of linear equations relatively predictable, based on the size of the matrix. In fact, for sparse matrices, the solution time can be predicted based on the number of non-zero elements in the array A .

Matrix Fundamentals

A matrix is a rectangular array of either real or complex numbers. A matrix is denoted by a capital letter; its elements are denoted by the same lower case letter with row/column subscripts. Thus, the value of the element in row i and column j in matrix A is denoted by $a(i, j)$. For example, a 3 by 4 matrix A , is written as follows:

$$A = \begin{bmatrix} a(1, 1) & a(1, 2) & a(1, 3) & a(1, 4) \\ a(2, 1) & a(2, 2) & a(2, 3) & a(2, 4) \\ a(3, 1) & a(3, 2) & a(3, 3) & a(3, 4) \end{bmatrix}$$

Note that with the above notation, we assume the standard Fortran programming language convention of starting array indices at 1 rather than the C programming language convention of starting them at 0.

A matrix in which all of the elements are real numbers is called a real matrix. A matrix that contains at least one complex number is called a complex matrix. A real or complex matrix A with the property that $a(i,j) = a(j,i)$, is called a symmetric matrix. A complex matrix A with the property that $a(i,j) = \text{conj}(a(j,i))$, is called a Hermitian matrix. Note that programs that manipulate symmetric and Hermitian matrices need only store half of the matrix values, since the values of the non-stored elements can be quickly reconstructed from the stored values.

A matrix that has the same number of rows as it has columns is referred to as a square matrix. The elements in a square matrix that have same row index and column index are called the diagonal elements of the matrix, or simply the diagonal of the matrix.

The transpose of a matrix A is the matrix obtained by “flipping” the elements of the array about its diagonal. That is, we exchange the elements $a(i,j)$ and $a(j,i)$. For a complex matrix, if we both flip the elements about the diagonal and then take the complex conjugate of the element, the resulting matrix is called the Hermitian transpose or conjugate transpose of the original matrix. The transpose and Hermitian transpose of a matrix A are denoted by A^T and A^H respectively.

A column vector, or simply a vector, is a $n \times 1$ matrix, and a row vector is a $1 \times n$ matrix. A real or complex matrix A is said to be positive definite if the vector-matrix product $x^T A x$ is greater than zero for all non-zero vectors x . A matrix that is not positive definite is referred to as indefinite.

An upper (or lower) triangular matrix, is a square matrix in which all elements below (or above) the diagonal are zero. A unit triangular matrix is an upper or lower triangular matrix with all 1's along the diagonal.

A matrix P is called a permutation matrix if, for any matrix A , the result of the matrix product PA is identical to A except for interchanging the rows of A . For a square matrix, it can be shown that if PA is a permutation of the rows of A , then AP^T is the same permutation of the columns of A . Additionally, it can be shown that the inverse of P is P^T .

In order to save space, a permutation matrix is usually stored as a linear array, called a permutation vector, rather than as an array. Specifically, if the permutation matrix maps the i -th row of a matrix to the j -th row, then the i -th element of the permutation vector is j .

A matrix with non-zero elements only on the diagonal is called a diagonal matrix. As is the case with a permutation matrix, it is usually stored as a vector of values, rather than as a matrix.

Direct Method

For solvers that use the direct method, the basic technique employed in finding the solution of the system $Ax = b$ is to first factor A into triangular matrices. That is, find a lower triangular matrix L and an upper triangular matrix U , such that $A = LU$. Having obtained such a factorization (usually referred to as an LU decomposition or LU factorization), the solution to the original problem can be rewritten as follows.

$$\begin{aligned} Ax &= b \\ \Rightarrow LUx &= b \\ \Rightarrow L(Ux) &= b \end{aligned}$$

This leads to the following two-step process for finding the solution to the original system of equations:

1. Solve the systems of equations $Ly = b$.
2. Solve the system $Ux = y$.

Solving the systems $Ly = b$ and $Ux = y$ is referred to as a forward solve and a backward solve, respectively.

If a symmetric matrix A is also positive definite, it can be shown that A can be factored as LL^T where L is a lower triangular matrix. Similarly, a Hermitian matrix, A , that is positive definite can be factored as $A = LL^H$. For both symmetric and Hermitian matrices, a factorization of this form is called a Cholesky factorization.

In a Cholesky factorization, the matrix U in an LU decomposition is either L^T or L^H . Consequently, a solver can increase its efficiency by only storing L , and one-half of A , and not computing U . Therefore, users who can express their application as the solution of a system of positive definite equations will gain a significant performance improvement over using a general representation.

For matrices that are symmetric (or Hermitian) but not positive definite, there are still some significant efficiencies to be had. It can be shown that if A is symmetric but not positive definite, then A can be factored as $A = LDL^T$, where D is a diagonal matrix and L is a lower unit triangular matrix. Similarly, if A is Hermitian, it can be factored as $A = LDL^H$. In either case, we again only need to store L , D , and half of A and we need not compute U . However, the backward solve phases must be amended to solving $L^T x = D^{-1}y$ rather than $L^T x = y$.

Fill-In and Reordering of Sparse Matrices

Two important concepts associated with the solution of sparse systems of equations are fill-in and reordering. The following example illustrates these concepts.

Consider the system of linear equation $Ax = b$, where A is a symmetric positive definite sparse matrix, and A and b are defined by the following:

$$A = \begin{bmatrix} 9 & \frac{3}{2} & 6 & \frac{3}{4} & 3 \\ \frac{3}{2} & 1 & * & * & * \\ 6 & * & 12 & * & * \\ \frac{3}{4} & * & * & \frac{5}{8} & * \\ 3 & * & * & * & 16 \end{bmatrix}, b = \begin{bmatrix} 1 \\ 2 \\ 3 \\ 4 \\ 5 \end{bmatrix}$$

A star (*) is used to represent zeros and to emphasize the sparsity of A . The Cholesky factorization of A is: $A = LL^T$, where L is the following:

$$L = \begin{bmatrix} 3 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix}$$

Notice that even though the matrix A is relatively sparse, the lower triangular matrix L has no zeros below the diagonal. If we computed L and then used it for the forward and backward solve phase, we would do as much computation as if A had been dense.

The situation of L having non-zeros in places where A has zeros is referred to as fill-in. Computationally, it would be more efficient if a solver could exploit the non-zero structure of A in such a way as to reduce the fill-in when computing L . By doing this, the solver would only need to compute the non-zero entries in L . Toward this end, consider permuting the rows and columns of A . As described in [Matrix Fundamentals](#) section, the permutations of the rows of A can be represented as a permutation matrix, P . The result of permuting the rows is the product of P and A . Suppose, in the above example, we swap the first and fifth row

of A , then swap the first and fifth columns of A , and call the resulting matrix B . Mathematically, we can express the process of permuting the rows and columns of A to get B as $B = PAP^T$. After permuting the rows and columns of A , we see that B is given by the following:

$$B = \begin{bmatrix} 16 & * & * & * & 3 \\ * & \frac{1}{2} & * & * & \frac{3}{2} \\ * & * & 12 & * & 6 \\ * & * & * & \frac{5}{8} & \frac{3}{4} \\ 3 & \frac{3}{2} & 6 & \frac{3}{4} & 9 \end{bmatrix}$$

Since B is obtained from A by simply switching rows and columns, the numbers of non-zero entries in A and B are the same. However, when we find the Cholesky factorization, $B = LL^T$, we see the following:

$$L = \begin{bmatrix} 4 & * & * & * & * \\ * & \frac{1}{\sqrt{2}} & * & * & * \\ * & * & 2(\sqrt{3}) & * & * \\ * & * & * & \frac{\sqrt{10}}{4} & * \\ \frac{3}{4} & \frac{3}{\sqrt{2}} & \sqrt{3} & \frac{3}{\sqrt{10}} & \frac{\sqrt{3}}{4} \end{bmatrix}$$

The fill-in associated with B is much smaller than the fill-in associated with A . Consequently, the storage and computation time needed to factor B is much smaller than to factor A . Based on this, we see that an efficient sparse solver needs to find permutation P of the matrix A , which minimizes the fill-in for factoring $B = PAP^T$, and then use the factorization of B to solve the original system of equations.

Although the above example is based on a symmetric positive definite matrix and a Cholesky decomposition, the same approach works for a general LU decomposition. Specifically, let P be a permutation matrix, $B = PAP^T$ and suppose that B can be factored as $B = LU$. Then

$$Ax = b$$

$$\Rightarrow PA(P^{-1}P)x = Pb$$

$$\Rightarrow PA(P^T P)x = Pb$$

$$\Rightarrow (PAP^T)(Px) = Pb$$

$$\Rightarrow B(Px) = Pb$$

$$\Rightarrow LU(Px) = Pb$$

It follows that if we obtain an LU factorization for B , we can solve the original system of equations by a three step process:

1. Solve $Ly = Pb$.
2. Solve $Uz = y$.
3. Set $x = P^T z$.

If we apply this three-step process to the current example, we first need to perform the forward solve of the systems of equation $Ly = Pb$:

$$Ly = \begin{bmatrix} 4 & * & * & * & * \\ * & \frac{1}{\sqrt{2}} & * & * & * \\ * & * & 2(\sqrt{3}) & * & * \\ * & * & * & \frac{\sqrt{10}}{4} & * \\ \frac{3}{4} & \frac{3}{\sqrt{2}} & \sqrt{3} & \frac{3}{\sqrt{10}} & \frac{\sqrt{3}}{4} \end{bmatrix} * \begin{bmatrix} y1 \\ y2 \\ y3 \\ y4 \\ y5 \end{bmatrix} = \begin{bmatrix} 5 \\ 2 \\ 3 \\ 4 \\ 1 \end{bmatrix}$$

This gives: $y^T = \frac{5}{4}, 2\sqrt{2}, \frac{\sqrt{3}}{2}, \frac{16}{\sqrt{10}}, \frac{-979\sqrt{3}}{12}$.

The second step is to perform the backward solve, $Uz = y$. Or, in this case, since a Cholesky factorization is used, $L^T z = y$.

$$\begin{bmatrix} 4 & * & * & * & * \\ * & \frac{1}{\sqrt{2}} & * & * & * \\ * & * & 2(\sqrt{3}) & * & * \\ * & * & * & \frac{\sqrt{10}}{4} & * \\ \frac{3}{4} & \frac{3}{\sqrt{2}} & \sqrt{3} & \frac{3}{\sqrt{10}} & \frac{\sqrt{3}}{4} \end{bmatrix}^T * \begin{bmatrix} z1 \\ z2 \\ z3 \\ z4 \\ z5 \end{bmatrix} = \begin{bmatrix} \frac{5}{4} \\ 2(\sqrt{2}) \\ \frac{\sqrt{3}}{2} \\ \frac{16}{\sqrt{10}} \\ \frac{-979\sqrt{3}}{12} \end{bmatrix}$$

This gives $z^T = \frac{123}{2}, 983, \frac{1961}{12}, 398, \frac{-979}{3}$.

The third and final step is to set $x = P^T z$. This gives $x^T = \frac{-979}{3}, 983, \frac{1961}{12}, 398, \frac{123}{2}$.

Sparse Matrix Storage Formats

As discussed above, it is more efficient to store only the non-zero elements of a sparse matrix. There are a number of common storage formats used for sparse matrices, but most of them employ the same basic technique. That is, store all non-zero elements of the matrix into a linear array and provide auxiliary arrays to describe the locations of the non-zero elements in the original matrix.

Storage Formats for the Direct Sparse Solvers

Storing the non-zero elements of a sparse matrix into a linear array is done by walking down each column (column-major format) or across each row (row-major format) in order, and writing the non-zero elements to a linear array in the order they appear in the walk.

Sparse Matrix Storage Formats for Sparse BLAS Levels 2 and Level 3

These sections describe in detail the sparse matrix storage formats supported in the current version of the Intel MKL Sparse BLAS Level 2 and Level 3.

- [Sparse BLAS CSR Matrix Storage](#)
- [Sparse BLAS CSC Matrix Storage](#)
- [Sparse BLAS Coordinate Matrix Storage](#)
- [Sparse BLAS Diagonal Matrix Storage](#)
- [Sparse BLAS Skyline Matrix Storage](#)
- [Sparse BLAS BSR Matrix Storage](#)

DSS Symmetric Matrix Storage

For symmetric matrices, it is necessary to store only the upper triangular half of the matrix (upper triangular format) or the lower triangular half of the matrix (lower triangular format).

The Intel MKL direct sparse solvers use a row-major upper triangular storage format: the matrix is compressed row-by-row and for symmetric matrices only non-zero elements in the upper triangular half of the matrix are stored.

The Intel MKL sparse matrix storage format for direct sparse solvers is specified by three arrays: *values*, *columns*, and *rowIndex*. The following table describes the arrays in terms of the values, row, and column positions of the non-zero elements in a sparse matrix.

<i>values</i>	A real or complex array that contains the non-zero elements of a sparse matrix. The non-zero elements are mapped into the <i>values</i> array using the row-major upper triangular storage mapping described above.
<i>columns</i>	Element <i>i</i> of the integer array <i>columns</i> is the number of the column that contains the <i>i</i> -th element in the <i>values</i> array.

rowIndex Element j of the integer array *rowIndex* gives the index of the element in the *values* array that is first non-zero element in a row j .

The length of the *values* and *columns* arrays is equal to the number of non-zero elements in the matrix.

As the *rowIndex* array gives the location of the first non-zero element within a row, and the non-zero elements are stored consecutively, the number of non-zero elements in the i -th row is equal to the difference of *rowIndex*[i] and *rowIndex*[$i+1$].

To have this relationship hold for the last row of the matrix, an additional entry (dummy entry) is added to the end of *rowIndex*. Its value is equal to the number of non-zero elements plus one. This makes the total length of the *rowIndex* array one larger than the number of rows in the matrix.

NOTE

The Intel MKL sparse storage scheme for the direct sparse solvers supports both one-based indexing and zero-based indexing.

Consider the symmetric matrix A :

$$A = \begin{pmatrix} 1 & -1 & * & -3 & * \\ -1 & 5 & * & * & * \\ * & * & 4 & 6 & 4 \\ -3 & * & 6 & 7 & * \\ * & * & 4 & * & -5 \end{pmatrix}$$

Only elements from the upper triangle are stored. The actual arrays for the matrix A are as follows:

Storage Arrays for a Symmetric Matrix

one-based indexing

<i>values</i>	=	(1	-1	-3	5	4	6	4	7	-5)
<i>columns</i>	=	(1	2	4	2	3	4	5	4	5)
<i>rowIndex</i>	=	(1	4	5	8	9	10)			

zero-based indexing

<i>values</i>	=	(1	-1	-3	5	4	6	4	7	-5)
<i>columns</i>	=	(0	1	3	1	2	3	4	3	4)
<i>rowIndex</i>	=	(0	3	4	7	8	9)			

Storage Format Restrictions

The storage format for the sparse solver must conform to two important restrictions:

- the non-zero values in a given row must be placed into the *values* array in the order in which they occur in the row (from left to right);
- no diagonal element can be omitted from the *values* array for any symmetric or structurally symmetric matrix.

The second restriction implies that if symmetric or structurally symmetric matrices have zero diagonal elements, then they must be explicitly represented in the *values* array.

DSS Nonsymmetric Matrix Storage

For a non-symmetric or non-Hermitian matrix, all non-zero elements need to be stored. Consider the non-symmetric matrix B :

$$B = \begin{pmatrix} 1 & -1 & * & -3 & * \\ -2 & 5 & * & * & * \\ * & * & 4 & 6 & 4 \\ -4 & * & 2 & 7 & * \\ * & 8 & * & * & -5 \end{pmatrix}$$

The matrix B has 13 non-zero elements, and all of them are stored as follows:

Storage Arrays for a Non-Symmetric Matrix

one-based indexing

<i>values</i>	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)	
<i>columns</i>	=	(1	2	4	1	2	3	4	5	1	3	4	2	5)	
<i>rowIndex</i>	=	(1	4	6	9	12	14)								

zero-based indexing

<i>values</i>	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)	
<i>columns</i>	=	(0	1	3	0	1	2	3	4	0	2	3	1	4)	
<i>rowIndex</i>	=	(0	3	5	8	11	13)								

Storage Format Restrictions

The storage format for the sparse solver must conform to two important restrictions:

- the non-zero values in a given row must be placed into the *values* array in the order in which they occur in the row (from left to right);
- no diagonal element can be omitted from the *values* array for any symmetric or structurally symmetric matrix.

The second restriction implies that if symmetric or structurally symmetric matrices have zero diagonal elements, then they must be explicitly represented in the *values* array.

DSS Structurally Symmetric Matrix Storage

Direct sparse solvers can also solve symmetrically structured systems of equations. A symmetrically structured system of equations is one where the pattern of non-zero elements is symmetric. That is, a matrix has a symmetric structure if $a_{j,i}$ is not zero if and only if $a_{i,j}$ is not zero. From the point of view of the solver software, a "non-zero" element of a matrix is any element stored in the *values* array, even if its value is equal to 0. In that sense, any non-symmetric matrix can be turned into a symmetrically structured matrix by carefully adding zeros to the *values* array. For example, the above matrix B can be turned into a symmetrically structured matrix by adding two non-zero entries:

$$B = \begin{pmatrix} 1 & -1 & * & 3 & * \\ -2 & 5 & * & * & 0 \\ * & * & 4 & 6 & 4 \\ -4 & * & 2 & 7 & * \\ * & 8 & 0 & * & -5 \end{pmatrix}$$

The matrix B can be considered to be symmetrically structured with 15 non-zero elements and represented as:

Storage Arrays for a Symmetrically Structured Matrix

one-based indexing

<i>values</i>	=	(1	-1	-3	-2	5	0	4	6	4	-4	2	7	8	0	-5)	
<i>columns</i>	=	(1	2	4	1	2	5	3	4	5	1	3	4	2	3	5)	
<i>rowIndex</i>	=	(1	4	7	10	13	16)										

zero-based indexing

<i>values</i>	=	(1	-1	-3	-2	5	0	4	6	4	-4	2	7	8	0	-5)	
<i>columns</i>	=	(0	1	3	0	1	4	2	3	4	0	2	3	1	2	4)	
<i>rowIndex</i>	=	(0	3	6	9	12	15)										

Storage Format Restrictions

The storage format for the sparse solver must conform to two important restrictions:

- the non-zero values in a given row must be placed into the *values* array in the order in which they occur in the row (from left to right);
- no diagonal element can be omitted from the *values* array for any symmetric or structurally symmetric matrix.

The second restriction implies that if symmetric or structurally symmetric matrices have zero diagonal elements, then they must be explicitly represented in the *values* array.

DSS Distributed Symmetric Matrix Storage

The distributed assembled matrix input format can be used by the Parallel Direct Sparse Solver for Clusters Interface.

In this format, the symmetric input matrix A is divided into sequential row subsets, or domains. Each domain belongs to an MPI process. Neighboring domains can overlap. For such intersection between two domains, the element values of the full matrix can be obtained by summing the respective elements of both domains.

As in the centralized format, the distributed format uses three arrays to describe the input data, but the *values*, *columns*, and *rowIndex* arrays on each processor only describe the domain belonging to that particular processor and not the entire matrix.

For example, consider a symmetric matrix A :

$$A = \begin{pmatrix} 6 & -1 & * & -3 & * \\ -1 & 5 & * & * & * \\ * & * & 11 & 5 & 4 \\ -3 & * & 5 & 10 & * \\ * & * & 4 & * & 5 \end{pmatrix}$$

This array could be distributed between two domains corresponding to two MPI processes, with the first containing rows 1 through 3, and the second containing rows 3 through 5.

NOTE

For the symmetric input matrix, it is not necessary to store the values from the lower triangle.

$$A_{Domain\ 1} = \begin{pmatrix} 6 & -1 & * & -3 & * \\ -1 & 5 & * & * & * \\ * & * & 3 & * & 2 \end{pmatrix}$$

Distributed Storage Arrays for a Symmetric Matrix, Domain 1

one-based indexing

<i>values</i>	=	(6	-1	-3	5	3	2)
<i>columns</i>	=	(1	2	4	2	3	5)
<i>rowIndex</i>	=	(1	4	5	7)		

zero-based indexing

<i>values</i>	=	(6	-1	-3	5	3	2)
<i>columns</i>	=	(0	1	3	1	2	4)
<i>rowIndex</i>	=	(0	3	4	6)		

$$A_{Domain\ 2} = \begin{pmatrix} * & * & 8 & 5 & 2 \\ -3 & * & 5 & 10 & * \\ * & * & 4 & * & 5 \end{pmatrix}$$

Distributed Storage Arrays for a Symmetric Matrix, Domain 2

one-based indexing

<i>values</i>	=	(8	5	2	10	5)
<i>columns</i>	=	(3	4	5	4	5)
<i>rowIndex</i>	=	(1	4	5	6)	

zero-based indexing

<i>values</i>	=	(8	5	2	10	5)

<i>columns</i>	=	(2	3	4	3	4)
<i>rowIndex</i>	=	(0	3	4	5)	

The third row of matrix *A* is common between domain 1 and domain 2. The values of row 3 of matrix *A* are the sums of the respective elements of row 3 of matrix *A*_{Domain1} and row 1 of matrix *A*_{Domain2}.

Storage Format Restrictions

The storage format for the sparse solver must conform to two important restrictions:

- the non-zero values in a given row must be placed into the *values* array in the order in which they occur in the row (from left to right);
- no diagonal element can be omitted from the *values* array for any symmetric or structurally symmetric matrix.

The second restriction implies that if symmetric or structurally symmetric matrices have zero diagonal elements, then they must be explicitly represented in the *values* array.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

Sparse BLAS CSR Matrix Storage Format

The Intel MKL compressed sparse row (CSR) format is specified by four arrays: the *values*, *columns*, *pointerB*, and *pointerE*. The following table describes the arrays in terms of the values, row, and column positions of the non-zero elements in a sparse matrix *A*.

<i>values</i>	A real or complex array that contains the non-zero elements of <i>A</i> . Values of the non-zero elements of <i>A</i> are mapped into the <i>values</i> array using the row-major storage mapping described above.
<i>columns</i>	Element <i>i</i> of the integer array <i>columns</i> is the number of the column in <i>A</i> that contains the <i>i</i> -th value in the <i>values</i> array.
<i>pointerB</i>	Element <i>j</i> of this integer array gives the index of the element in the <i>values</i> array that is first non-zero element in a row <i>j</i> of <i>A</i> . Note that this index is equal to <i>pointerB</i> [<i>j</i>] - <i>pointerB</i> [0]+1.
<i>pointerE</i>	An integer array that contains row indices, such that <i>pointerE</i> [<i>j</i>] - <i>pointerB</i> [0] is the index of the element in the <i>values</i> array that is last non-zero element in a row <i>j</i> of <i>A</i> .

The length of the *values* and *columns* arrays is equal to the number of non-zero elements in *A*. The length of the *pointerB* and *pointerE* arrays is equal to the number of rows in *A*.

NOTE

Note that the Intel MKL Sparse BLAS routines support the CSR format both with one-based indexing and zero-based indexing.

The matrix *B*

$$B = \begin{pmatrix} 1 & -1 & * & -3 & * \\ -2 & 5 & * & * & * \\ * & * & 4 & 6 & 4 \\ -4 & * & 2 & 7 & * \\ * & 8 & * & * & -5 \end{pmatrix}$$

can be represented in the CSR format as:

Storage Arrays for a Matrix in CSR Format

one-based indexing

<i>values</i>	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)	
<i>columns</i>	=	(1	2	4	1	2	3	4	5	1	3	4	2	5)	
<i>pointerB</i>	=	(1	4	6	9	12)									
<i>pointerE</i>	=	(4	6	9	12	14)									

zero-based indexing

<i>values</i>	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)	
<i>columns</i>	=	(0	1	3	0	1	2	3	4	0	2	3	1	4)	
<i>pointerB</i>	=	(0	3	5	8	11)									
<i>pointerE</i>	=	(3	5	8	11	13)									

This storage format is used in the NIST Sparse BLAS library [[Rem05](#)].

Three Array Variation of CSR Format

The storage format accepted for the direct sparse solvers is a variation of the CSR format. It also is used in the Intel MKL Sparse BLAS Level 2 both with one-based indexing and zero-based indexing. The above matrix *B* can be represented in this format (referred to as the 3-array variation of the CSR format or CSR3) as:

Storage Arrays for a Matrix in CSR Format (3-Array Variation)

one-based indexing

<i>values</i>	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)	
<i>columns</i>	=	(1	2	4	1	2	3	4	5	1	3	4	2	5)	
<i>rowIndex</i>	=	(1	4	6	9	12	14)								

zero-based indexing

<i>values</i>	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)	
<i>columns</i>	=	(0	1	3	0	1	2	3	4	0	2	3	1	4)	
<i>rowIndex</i>	=	(0	3	5	8	11	13)								

The 3-array variation of the CSR format has a restriction: all non-zero elements are stored continuously, that is the set of non-zero elements in the row *J* goes just after the set of non-zero elements in the row *J*-1.

There are no such restrictions in the general (NIST) CSR format. This may be useful, for example, if there is a need to operate with different submatrices of the matrix at the same time. In this case, it is enough to define the arrays *pointerB* and *pointerE* for each needed submatrix so that all these arrays are pointers to the same array *values*.

By definition, the array *rowIndex* from the [Table "Storage Arrays for a Non-Symmetric Example Matrix"](#) is related to the arrays *pointerB* and *pointerE* from the [Table "Storage Arrays for an Example Matrix in CSR Format"](#), and you can see that

```
pointerB[i] = rowIndex[i] for i=0, ..4;
pointerE[i] = rowIndex[i+1] for i=0, ..4.
```

This enables calling a routine that has *values*, *columns*, *pointerB* and *pointerE* as input parameters for a sparse matrix stored in the format accepted for the direct sparse solvers. For example, a routine with the interface:

```
void name_routine(... , double *values, MKL_INT *columns, MKL_INT *pointerB, MKL_INT
*pointerE, ...)
```

can be called with parameters *values*, *columns*, *rowIndex* as follows:

```
name_routine(... , values, columns, rowIndex, rowIndex+1, ...).
```

Sparse BLAS CSC Matrix Storage Format

The compressed sparse column format (CSC) is similar to the CSR format, but the columns are used instead the rows. In other words, the CSC format is identical to the CSR format for the transposed matrix. The CSR format is specified by four arrays: *values*, *columns*, *pointerB*, and *pointerE*. The following table describes the arrays in terms of the values, row, and column positions of the non-zero elements in a sparse matrix *A*.

<i>values</i>	A real or complex array that contains the non-zero elements of <i>A</i> . Values of the non-zero elements of <i>A</i> are mapped into the <i>values</i> array using the column-major storage mapping.
<i>rows</i>	Element <i>i</i> of the integer array <i>rows</i> is the number of the row in <i>A</i> that contains the <i>i</i> -th value in the <i>values</i> array.
<i>pointerB</i>	Element <i>j</i> of this integer array gives the index of the element in the <i>values</i> array that is first non-zero element in a column <i>j</i> of <i>A</i> . Note that this index is equal to <i>pointerB</i> [<i>j</i>] - <i>pointerB</i> [0]+1.
<i>pointerE</i>	An integer array that contains column indices, such that <i>pointerE</i> [<i>j</i>] - <i>pointerB</i> [0] is the index of the element in the <i>values</i> array that is last non-zero element in a column <i>j</i> of <i>A</i> .

The length of the *values* and *columns* arrays is equal to the number of non-zero elements in *A*. The length of the *pointerB* and *pointerE* arrays is equal to the number of columns in *A*.

NOTE

Note that the Intel MKL Sparse BLAS routines support the CSC format both with one-based indexing and zero-based indexing.

For example, consider matrix *B*:

$$B = \begin{pmatrix} 1 & -1 & * & -3 & * \\ -2 & 5 & * & * & * \\ * & * & 4 & 6 & 4 \\ -4 & * & 2 & 7 & * \\ * & 8 & * & * & -5 \end{pmatrix}$$

It can be represented in the CSC format as:

Storage Arrays for a Matrix in CSC Format

one-based indexing														
values	=	(1	-2	-4	-1	5	8	4	2	-3	6	7	4	-5)
rows	=	(1	2	4	1	2	5	3	4	1	3	4	3	5)
pointerB	=	(1	4	7	9	12)								
pointerE	=	(4	7	9	12	14)								
zero-based indexing														
values	=	(1	-2	-4	-1	5	8	4	2	-3	6	7	4	-5)
rows	=	(0	1	3	0	1	4	2	3	0	2	3	2	4)
pointerB	=	(0	3	6	8	11)								
pointerE	=	(3	6	8	11	13)								

Sparse BLAS Coordinate Matrix Storage Format

The coordinate format is the most flexible and simplest format for the sparse matrix representation. Only non-zero elements are stored, and the coordinates of each non-zero element are given explicitly. Many commercial libraries support the matrix-vector multiplication for the sparse matrices in the coordinate format.

The Intel MKL coordinate format is specified by three arrays: *values*, *rows*, and *columns*, and a parameter *nnz* which is number of non-zero elements in *A*. All three arrays have dimension *nnz*. The following table describes the arrays in terms of the values, row, and column positions of the non-zero elements in a sparse matrix *A*.

<i>values</i>	A real or complex array that contains the non-zero elements of <i>A</i> in any order.
<i>rows</i>	Element <i>i</i> of the integer array <i>rows</i> is the number of the row in <i>A</i> that contains the <i>i</i> -th value in the <i>values</i> array.
<i>columns</i>	Element <i>i</i> of the integer array <i>columns</i> is the number of the column in <i>A</i> that contains the <i>i</i> -th value in the <i>values</i> array.

NOTE

Note that the Intel MKL Sparse BLAS routines support the coordinate format both with one-based indexing and zero-based indexing.

For example, the sparse matrix *C*

$$C = \begin{pmatrix} 1 & -1 & -3 & 0 & 0 \\ -2 & 5 & 0 & 0 & 0 \\ 0 & 0 & 4 & 6 & 4 \\ -4 & 0 & 2 & 7 & 0 \\ 0 & 8 & 0 & 0 & -5 \end{pmatrix}$$

can be represented in the coordinate format as follows:

Storage Arrays for an Example Matrix in case of the coordinate format

one-based indexing														
values	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
rows	=	(1	1	1	2	2	3	3	3	4	4	4	5	5)
columns	=	(1	2	3	1	2	3	4	5	1	3	4	2	5)
zero-based indexing														
values	=	(1	-1	-3	-2	5	4	6	4	-4	2	7	8	-5)
rows	=	(0	0	0	1	1	2	2	2	3	3	3	4	4)
columns	=	(0	1	2	0	1	2	3	4	0	2	3	1	4)

Sparse BLAS Diagonal Matrix Storage Format

If the sparse matrix has diagonals containing only zero elements, then the diagonal storage format can be used to reduce the amount of information needed to locate the non-zero elements. This storage format is particularly useful in many applications where the matrix arises from a finite element or finite difference discretization. The Intel MKL diagonal storage format is specified by two arrays: *values* and *distance*, and two parameters: *ndiag*, which is the number of non-empty diagonals, and *lval*, which is the declared leading dimension in the calling (sub)programs. The following table describes the arrays *values* and *distance*:

<i>values</i>	A real or complex two-dimensional array is dimensioned as <i>lval</i> by <i>ndiag</i> . Each column of it contains the non-zero elements of certain diagonal of <i>A</i> . The key point of the storage is that each element in <i>values</i> retains the row number of the

original matrix. To achieve this diagonals in the lower triangular part of the matrix are padded from the top, and those in the upper triangular part are padded from the bottom. Note that the value of *distance*[*i*] is the number of elements to be padded for diagonal *i*.

distance An integer array with dimension *ndiag*. Element *i* of the array *distance* is the distance between *i*-diagonal and the main diagonal. The distance is positive if the diagonal is above the main diagonal, and negative if the diagonal is below the main diagonal. The main diagonal has a distance equal to zero.

The above matrix *C* can be represented in the diagonal storage format as follows:

$$distance = (-3 \quad -1 \quad 0 \quad 1 \quad 2)$$

$$values = \begin{pmatrix} * & * & 1 & -1 & -3 \\ * & -2 & 5 & 0 & 0 \\ * & 0 & 4 & 6 & 4 \\ -4 & 2 & 7 & 0 & * \\ 8 & 0 & -5 & * & * \end{pmatrix}$$

where the asterisks denote padded elements.

When storing symmetric, Hermitian, or skew-symmetric matrices, it is necessary to store only the upper or the lower triangular part of the matrix.

For the Intel MKL triangular solver routines elements of the array *distance* must be sorted in increasing order. In all other cases the diagonals and distances can be stored in arbitrary order.

Sparse BLAS Skyline Matrix Storage Format

The skyline storage format is important for the direct sparse solvers, and it is well suited for Cholesky or LU decomposition when no pivoting is required.

The skyline storage format accepted in Intel MKL can store only triangular matrix or triangular part of a matrix. This format is specified by two arrays: *values* and *pointers*. The following table describes these arrays:

values A scalar array. For a lower triangular matrix it contains the set of elements from each row of the matrix starting from the first non-zero element to and including the diagonal element. For an upper triangular matrix it contains the set of elements from each column of the matrix starting with the first non-zero element down to and including the diagonal element. Encountered zero elements are included in the sets.

pointers An integer array with dimension $(m+1)$, where *m* is the number of rows for lower triangle (columns for the upper triangle). *pointers*[*i*] - *pointers*[0]+1 gives the index of element in *values* that is first non-zero element in row (column) *i*. The value of *pointers*[*m*] is set to *nnz*+*pointers*[0], where *nnz* is the number of elements in the array *values*.

For example, consider the matrix *C*:

$$C = \begin{pmatrix} 1 & -1 & -3 & 0 & 0 \\ -2 & 5 & 0 & 0 & 0 \\ 0 & 0 & 4 & 6 & 4 \\ -4 & 0 & 2 & 7 & 0 \\ 0 & 8 & 0 & 0 & -5 \end{pmatrix}$$

The low triangle of the matrix *C* given above can be stored as follows:

```
values = [ 1 -2 5 4 -4 0 2 7 8 0 0 -5 ]
pointers = [ 0 1 3 4 8 12 ]
```

and the upper triangle of this matrix C can be stored as follows:

```
values = [ 1  -1  5  -3  0  4  6  7  4  0  -5 ]
pointers = [ 0  1  3  6  8  11 ]
```

This storage format is supported by the NIST Sparse BLAS library [Rem05].

Note that the Intel MKL Sparse BLAS routines operating with the skyline storage format do not support general matrices.

Sparse BLAS BSR Matrix Storage Format

The Intel MKL block compressed sparse row (BSR) format for sparse matrices is specified by four arrays: *values*, *columns*, *pointerB*, and *pointerE*. The following table describes these arrays.

<i>values</i>	A real array that contains the elements of the non-zero blocks of a sparse matrix. The elements are stored block-by-block in row-major order. A non-zero block is the block that contains at least one non-zero element. All elements of non-zero blocks are stored, even if some of them are equal to zero. Within each non-zero block elements are stored in column-major order in the case of one-based indexing, and in row-major order in the case of the zero-based indexing.
<i>columns</i>	Element i of the integer array <i>columns</i> is the number of the column in the block matrix that contains the i -th non-zero block.
<i>pointerB</i>	Element j of this integer array gives the index of the element in the <i>columns</i> array that is first non-zero block in a row j of the block matrix.
<i>pointerE</i>	Element j of this integer array gives the index of the element in the <i>columns</i> array that contains the last non-zero block in a row j of the block matrix plus 1.

The length of the *values* array is equal to the number of all elements in the non-zero blocks, the length of the *columns* array is equal to the number of non-zero blocks. The length of the *pointerB* and *pointerE* arrays is equal to the number of block rows in the block matrix.

NOTE

Note that the Intel MKL Sparse BLAS routines support BSR format both with one-based indexing and zero-based indexing.

For example, consider the sparse matrix D

$$D = \begin{pmatrix} 1 & 0 & 6 & 7 & * & * \\ 2 & 1 & 8 & 2 & * & * \\ * & * & 1 & 4 & * & * \\ * & * & 5 & 1 & * & * \\ * & * & 4 & 3 & 7 & 2 \\ * & * & 0 & 0 & 0 & 0 \end{pmatrix}$$

If the size of the block equals 2, then the sparse matrix D can be represented as a 3x3 block matrix E with the following structure:

$$E = \begin{pmatrix} L & M & * \\ * & N & * \\ * & P & Q \end{pmatrix}$$

where

$$L = \begin{pmatrix} 1 & 0 \\ 2 & 1 \end{pmatrix}, \quad M = \begin{pmatrix} 6 & 7 \\ 8 & 2 \end{pmatrix}, \quad N = \begin{pmatrix} 1 & 4 \\ 5 & 1 \end{pmatrix}, \quad P = \begin{pmatrix} 4 & 3 \\ 0 & 0 \end{pmatrix}, \quad Q = \begin{pmatrix} 7 & 2 \\ 0 & 0 \end{pmatrix}$$

The matrix D can be represented in the BSR format as follows:

one-based indexing

```
values = (1 2 0 1 6 8 7 2 1 5 4 1 4 0 3 0 7 0 2 0)
columns = (1 2 2 2 3)
pointerB = (1 3 4)
pointerE = (3 4 6)
```

zero-based indexing

```
values = [1 0 2 1 6 7 8 2 1 4 5 1 4 3 0 0 7 2 0 0]
columns = [0 1 1 1 2]
pointerB = [0 2 3]
pointerE = [2 3 5]
```

This storage format is supported by the NIST Sparse BLAS library [[Rem05](#)].

Three Array Variation of BSR Format

Intel MKL supports the variation of the BSR format that is specified by three arrays: *values*, *columns*, and *rowIndex*. The following table describes these arrays.

<i>values</i>	A real array that contains the elements of the non-zero blocks of a sparse matrix. The elements are stored block by block in row-major order. A non-zero block is the block that contains at least one non-zero element. All elements of non-zero blocks are stored, even if some of them is equal to zero. Within each non-zero block the elements are stored in column major order in the case of the one-based indexing, and in row major order in the case of the zero-based indexing.
<i>columns</i>	Element <i>i</i> of the integer array <i>columns</i> is the number of the column in the block matrix that contains the <i>i</i> -th non-zero block.
<i>rowIndex</i>	Element <i>j</i> of this integer array gives the index of the element in the <i>columns</i> array that is first non-zero block in a row <i>j</i> of the block matrix.

The length of the *values* array is equal to the number of all elements in the non-zero blocks, the length of the *columns* array is equal to the number of non-zero blocks.

As the *rowIndex* array gives the location of the first non-zero block within a row, and the non-zero blocks are stored consecutively, the number of non-zero blocks in the *i*-th row is equal to the difference of *rowIndex*[*i*] and *rowIndex*[*i*+1].

To retain this relationship for the last row of the block matrix, an additional entry (dummy entry) is added to the end of *rowIndex* with value equal to the number of non-zero blocks plus one. This makes the total length of the *rowIndex* array one larger than the number of rows of the block matrix.

The above matrix *D* can be represented in this 3-array variation of the BSR format as follows:

one-based indexing

```
values = [1 2 0 1 6 8 7 2 1 5 4 2 4 0 3 0 7 0 2 0]
columns = [1 2 2 2 3]
rowIndex = [1 3 4 6]
```

zero-based indexing

```
values = [1 0 2 1 6 7 8 2 1 4 5 1 4 3 0 0 7 2 0 0]
columns = [0 1 1 1 2]
rowIndex = [0 2 3 5]
```

When storing symmetric matrices, it is necessary to store only the upper or the lower triangular part of the matrix.

For example, consider the symmetric sparse matrix *F*:

$$F = \begin{pmatrix} 1 & 0 & 6 & 7 & * & * \\ 2 & 1 & 8 & 2 & * & * \\ 6 & 8 & 1 & 4 & * & * \\ 7 & 2 & 5 & 2 & * & * \\ * & * & * & * & 7 & 2 \\ * & * & * & * & 0 & 0 \end{pmatrix}$$

If the size of the block equals 2, then the sparse matrix F can be represented as a 3x3 block matrix G with the following structure:

$$G = \begin{pmatrix} L & M & * \\ M' & N & * \\ * & * & Q \end{pmatrix}$$

where

$$L = \begin{pmatrix} 1 & 0 \\ 2 & 1 \end{pmatrix}, M = \begin{pmatrix} 6 & 7 \\ 8 & 2 \end{pmatrix}, M' = \begin{pmatrix} 6 & 8 \\ 7 & 2 \end{pmatrix}, N = \begin{pmatrix} 1 & 4 \\ 5 & 2 \end{pmatrix}, \text{ and } Q = \begin{pmatrix} 7 & 2 \\ 0 & 0 \end{pmatrix}$$

The symmetric matrix F can be represented in this 3-array variation of the BSR format (storing only the upper triangular part) as follows:

one-based indexing

```
values = [1 2 0 1 6 8 7 2 1 5 4 2 7 0 2 0]
columns = [1 2 2 3]
rowIndex = [1 3 4 5]
```

zero-based indexing

```
values = [1 0 2 1 6 7 8 2 1 4 5 2 7 2 0 0]
columns = [0 1 1 2]
rowIndex = [0 2 3 4]
```

Variable BSR Format

A variation of BSR3 is variable block compressed sparse row format. For a trust level t , $0 \leq t \leq 100$, rows similar up to t percent are placed in one supernode.

Routine and Function Arguments

The major arguments in the BLAS routines are vector and matrix, whereas VM functions work on vector arguments only. The sections that follow discuss each of these arguments and provide examples.

Vector Arguments in BLAS

Vector arguments are passed in one-dimensional arrays. The array dimension (length) and vector increment are passed as integer variables. The length determines the number of elements in the vector. The increment (also called stride) determines the spacing between vector elements and the order of the elements in the array in which the vector is passed.

A vector of length n and increment $incx$ is passed in a one-dimensional array x whose values are defined as

```
x[0], x[|incx|], ..., x[(n-1)*|incx|]
```

If $incx$ is positive, then the elements in array x are stored in increasing order. If $incx$ is negative, the elements in array x are stored in decreasing order with the first element defined as $x[(n-1)*|incx|]$. If $incx$ is zero, then all elements of the vector have the same value, $x[0]$. The size of the one-dimensional array that stores the vector must always be at least

```
idimx = 1 + (n-1)*|incx|
```

Example. One-dimensional Real Array

Let $x[0:6]$ be the one-dimensional real array

```
x = [1.0, 3.0, 5.0, 7.0, 9.0, 11.0, 13.0].
```

If $incx = 2$ and $n = 3$, then the vector argument with elements in order from first to last is $[1.0, 5.0, 9.0]$.

If $incx = -2$ and $n = 4$, then the vector elements in order from first to last is $[13.0, 9.0, 5.0, 1.0]$.

If $incx = 0$ and $n = 4$, then the vector elements in order from first to last is $[1.0, 1.0, 1.0, 1.0]$.

One-dimensional substructures of a matrix, such as the rows, columns, and diagonals, can be passed as vector arguments with the starting address and increment specified.

Storage of the m -by- n matrix can be based on either column-major ordering where the increment between elements in the same column is 1, the increment between elements in the same row is m , and the increment between elements on the same diagonal is $m + 1$; or row-major ordering where the increment between elements in the same row is 1, the increment between elements in the same column is n , and the increment between elements on the same diagonal is $n + 1$.

Example. Two-dimensional Real Matrix

Let a be a real 5×4 matrix declared as .

To scale the third column of a by 2.0, use the BLAS routine `sscal` with the following calling sequence:

```
cblas_sscal (5, 2.0, a[2], 4)
```

To scale the second row, use the statement:

```
cblas_sscal (4, 2.0, a[4], 1)
```

To scale the main diagonal of a by 2.0, use the statement:

```
cbblas_sscal (4, 2.0, a[0], 5)
```

NOTE

The default vector argument is assumed to be 1.

Vector Arguments in VM

Vector arguments of VM mathematical functions are passed in one-dimensional arrays with unit vector increment. It means that a vector of length n is passed contiguously in an array a whose values are defined as

$a[0], a[1], \dots, a[n-1]$.

To accommodate for arrays with other increments, or more complicated indexing, VM contains auxiliary pack/unpack functions that gather the array elements into a contiguous vector and then scatter them after the computation is complete.

Generally, if the vector elements are stored in a one-dimensional array a as

$a[m0], a[m1], \dots, a[mn-1]$

and need to be regrouped into an array y as

$y[k0], y[k1], \dots, y[kn-1],$.

VM pack/unpack functions can use one of the following indexing methods:

Positive Increment Indexing

$kj = incy * j, mj = inca * j, j = 0, \dots, n-1$.

Constraint: $incy > 0$ and $inca > 0$.

For example, setting $incy = 1$ specifies gathering array elements into a contiguous vector.

This method is similar to that used in BLAS, with the exception that negative and zero increments are not permitted.

Index Vector Indexing

$kj = iy[j], mj = ia[j], j = 0, \dots, n-1,$.

where ia and iy are arrays of length n that contain index vectors for the input and output arrays a and y , respectively.

Mask Vector Indexing

Indices kj, mj are such that:

$my[kj] \neq 0, ma[mj] \neq 0, j = 0, \dots, n-1,$.

where ma and my are arrays that contain mask vectors for the input and output arrays a and y , respectively.

Matrix Arguments

Matrix arguments of the Intel® Math Kernel Library routines can be stored in arrays, using the following storage schemes:

- [conventional full storage](#)
- [packed storage](#) for Hermitian, symmetric, or triangular matrices
- [band storage](#) for band matrices
- [rectangular full packed storage](#) for symmetric, Hermitian, or triangular matrices as compact as the Packed storage while maintaining efficiency by using Level 3 BLAS/LAPACK kernels.

Full storage is the simplest scheme. A matrix A is stored in a one-dimensional array a , with the matrix element a_{ij} stored in the array element $a[i - 1 + (j - 1)*lda]$, where lda is the leading dimension of array a .

If a matrix is triangular (upper or lower, as specified by the argument *uplo*), only the elements of the relevant triangle are stored; the remaining elements of the array need not be set.

Routines that handle symmetric or Hermitian matrices allow for either the upper or lower triangle of the matrix to be stored in the corresponding elements of the array:

if *uplo* = 'U', a_{ij} is stored as described for $i \leq j$, other elements of a need not be set.

if *uplo* = 'L', a_{ij} is stored as described for $j \leq i$, other elements of a need not be set.

Packed storage allows you to store symmetric, Hermitian, or triangular matrices more compactly: the relevant triangle (again, as specified by the argument *uplo*) is packed by columns in a one-dimensional array ap :

if *uplo* = 'U', a_{ij} is stored in $ap[i - 1 + j(j - 1)/2]$ for $i \leq j$

if *uplo* = 'L', a_{ij} is stored in $ap[i - 1 + (2*n - j)*(j - 1)/2]$ for $j \leq i$.

In descriptions of LAPACK routines, arrays with packed matrices have names ending in p .

Band storage is as follows: an m -by- n band matrix with kl non-zero sub-diagonals and ku non-zero super-diagonals is stored compactly in an array ab with $(kl+ku+1)*n$ elements. Thus,

a_{ij} is stored in $ab(ku+1+i-j,j)$ for $\max(1, j-ku) \leq i \leq \min(n, j+kl)$.

Use the band storage scheme only when kl and ku are much less than the matrix size n . Although the routines work correctly for all values of kl and ku , using the band storage is inefficient if your matrices are not really banded.

The band storage scheme is illustrated by the following example, when

$m = n = 6, kl = 2, ku = 1$

Array elements marked * are not used by the routines:

Banded matrix A						Band storage of A					
a_{11}	a_{12}	0	0	0	0						
a_{21}	a_{22}	a_{23}	0	0	0	*	a_{12}	a_{23}	a_{34}	a_{45}	a_{56}
a_{31}	a_{32}	a_{33}	a_{34}	0	0	a_{11}	a_{22}	a_{33}	a_{44}	a_{55}	a_{66}
0	a_{42}	a_{43}	a_{44}	a_{45}	0	a_{21}	a_{32}	a_{43}	a_{54}	a_{65}	*
0	0	a_{53}	a_{54}	a_{55}	a_{56}	a_{31}	a_{42}	a_{53}	a_{64}	*	*
0	0	0	a_{64}	a_{65}	a_{66}						

When a general band matrix is supplied for *LU factorization*, space must be allowed to store kl additional super-diagonals generated by fill-in as a result of row interchanges. This means that the matrix is stored according to the above scheme, but with $kl + ku$ super-diagonals. Thus,

a_{ij} is stored in $ab(kl+ku+1+i-j, j)$ for $\max(1, j-ku) \leq i \leq \min(n, j+kl)$.

The band storage scheme for LU factorization is illustrated by the following example, when $m = n = 6$, $kl = 2$, $ku = 1$:

Banded matrix A						Band storage of A					
a_{11}	a_{12}	0	0	0	0	*	*	*	+	+	+
a_{21}	a_{22}	a_{23}	0	0	0	*	*	+	+	+	+
a_{31}	a_{32}	a_{33}	a_{34}	0	0	*	a_{12}	a_{23}	a_{34}	a_{45}	a_{56}
0	a_{42}	a_{43}	a_{44}	a_{45}	0	a_{11}	a_{22}	a_{33}	a_{44}	a_{55}	a_{66}
0	0	a_{53}	a_{54}	a_{55}	a_{56}	a_{21}	a_{32}	a_{43}	a_{54}	a_{65}	*
0	0	0	a_{64}	a_{65}	a_{66}	a_{31}	a_{42}	a_{53}	a_{64}	*	*

Array elements marked * are not used by the routines; elements marked + need not be set on entry, but are required by the LU factorization routines to store the results. The input array will be overwritten on exit by the details of the LU factorization as follows:

```

      ... | ...
      ... | ...
      ... | ...

      .....:|... ..
      .....:|... ..
      .....:|... ..

```

where u_{ij} are the elements of the upper triangular matrix U, and m_{ij} are the multipliers used during factorization.

Triangular band matrices are stored in the same format, with either $kl = 0$ if upper triangular, or $ku = 0$ if lower triangular. For symmetric or Hermitian band matrices with k sub-diagonals or super-diagonals, you need to store only the upper or lower triangle, as specified by the argument *uplo*:

if *uplo* = 'U', a_{ij} is stored in $ab(k+1+i-j,j)$ for $\max(1,j-k) \leq i \leq j$

if *uplo* = 'L', a_{ij} is stored in $ab(1+i-j,j)$ for $j \leq i \leq \min(n,j+k)$.

In descriptions of LAPACK routines, arrays that hold matrices in band storage have names ending in *b*.

In Fortran, column-major ordering of storage is assumed. This means that elements of the same column occupy successive storage locations.

Three quantities are usually associated with a two-dimensional array argument: its leading dimension, which specifies the number of storage locations between elements in the same row, its number of rows, and its number of columns. For a matrix in full storage, the leading dimension of the array must be at least as large as the number of rows in the matrix.

A character transposition parameter is often passed to indicate whether the matrix argument is to be used in normal or transposed form or, for a complex matrix, if the conjugate transpose of the matrix is to be used.

The values of the transposition parameter for these three cases are the following:

'N' or 'n' normal (no conjugation, no transposition)

'T' or 't'	transpose
'C' or 'c'	conjugate transpose.

Example. Two-Dimensional Complex Array

Suppose A (1:5, 1:4) is the complex two-dimensional array presented by matrix

$$\begin{bmatrix} (1.1, 0.11) & (1.2, 0.12) & (1.3, 0.13) & (1.4, 0.14) \\ (2.1, 0.21) & (2.2, 0.22) & (2.3, 0.23) & (1.4, 0.24) \\ (3.1, 0.31) & (3.2, 0.32) & (3.3, 0.33) & (1.4, 0.34) \\ (4.1, 0.41) & (4.2, 0.42) & (4.3, 0.43) & (1.4, 0.44) \\ (5.1, 0.51) & (5.2, 0.52) & (5.3, 0.53) & (1.4, 0.54) \end{bmatrix}$$

Let *transa* be the transposition parameter, *m* be the number of rows, *n* be the number of columns, and *lda* be the leading dimension. Then if

transa = 'N', *m* = 4, *n* = 2, and *lda* = 5, the matrix argument would be

$$\begin{bmatrix} (1.1, 0.11) & (1.2, 0.12) \\ (2.1, 0.21) & (2.2, 0.22) \\ (3.1, 0.31) & (3.2, 0.32) \\ (4.1, 0.41) & (4.2, 0.42) \end{bmatrix}$$

If *transa* = 'T', *m* = 4, *n* = 2, and *lda* = 5, the matrix argument would be

$$\begin{bmatrix} \dots\dots\dots & (1.1, 0.11) & (1.2, 0.12) & \dots\dots\dots & \dots\dots\dots & \dots\dots\dots & \dots\dots\dots \\ \dots\dots\dots & (2.1, 0.21) & (2.2, 0.22) & \dots\dots\dots & \dots\dots\dots & \dots\dots\dots & \dots\dots\dots \\ \dots\dots\dots & (3.1, 0.31) & (3.2, 0.32) & \dots\dots\dots & \dots\dots\dots & \dots\dots\dots & \dots\dots\dots \\ \dots\dots\dots & (4.1, 0.41) & (4.2, 0.42) & \dots\dots\dots & \dots\dots\dots & \dots\dots\dots & \dots\dots\dots \end{bmatrix}$$

If *transa* = 'C', *m* = 4, *n* = 2, and *lda* = 5, the matrix argument would be

$$\begin{bmatrix} (1.1, -0.11) & (2.1, -0.21) & (3.1, -0.31) & (4.1, -0.41) \\ (1.2, -0.12) & (2.2, -0.22) & (3.2, -0.32) & (4.2, -0.42) \end{bmatrix}$$

Note that care should be taken when using a leading dimension value which is different from the number of rows specified in the declaration of the two-dimensional array. For example, suppose the array *A* above is declared as a complex 5-by-4 matrix.

Then if *transa* = 'N', *m* = 3, *n* = 4, and *lda* = 4, the matrix argument will be

$$\begin{bmatrix} (1.1, 0.11) & (5.1, 0.51) & (4.2, 0.42) & (3.3, 0.33) \\ (2.1, 0.21) & (1.2, 0.12) & (5.2, 0.52) & (4.3, 0.43) \\ (3.1, 0.31) & (2.2, 0.22) & (1.3, 0.13) & (5.3, 0.53) \end{bmatrix}$$

Rectangular Full Packed storage allows you to store symmetric, Hermitian, or triangular matrices as compact as the Packed storage while maintaining efficiency by using Level 3 BLAS/LAPACK kernels. To store an n -by- n triangle (and suppose for simplicity that n is even), you partition the triangle into three parts: two $n/2$ -by- $n/2$ triangles and an $n/2$ -by- $n/2$ square, then pack this as an n -by- $n/2$ rectangle (or $n/2$ -by- n rectangle), by transposing (or transpose-conjugating) one of the triangles and packing it next to the other triangle. Since the two triangles are stored in full storage, you can use existing efficient routines on them.

There are eight cases of RFP storage representation: when n is even or odd, the packed matrix is transposed or not, the triangular matrix is lower or upper. See below for all the eight storage schemes illustrated:

n is odd, A is lower triangular

Intel MKL provides a number of routines such as [?hfrk](#), [?sfrk](#) performing BLAS operations working directly on RFP matrices, as well as some conversion routines, for instance, [?tpttf](#) goes from the standard packed format to RFP and [?trttf](#) goes from the full format to RFP.

Please refer to the Netlib site for more information.

Note that in the descriptions of LAPACK routines, arrays with RFP matrices have names ending in `fp`.

FFTW Interface to Intel® Math Kernel Library

Intel® Math Kernel Library (Intel® MKL) offers FFTW2 and FFTW3 interfaces to Intel MKL Fast Fourier Transform and Trigonometric Transform functionality. The purpose of these interfaces is to enable applications using FFTW (www.fftw.org) to gain performance with Intel MKL without changing the program source code.

Both FFTW2 and FFTW3 interfaces are provided in open source as FFTW wrappers to Intel MKL. For ease of use, FFTW3 interface is also integrated in Intel MKL.

Notational Conventions

This appendix typically employs path notations for Windows* OS.

FFTW2 Interface to Intel® Math Kernel Library

This section describes a collection of C and Fortran wrappers providing FFTW 2.x interface to Intel MKL. The wrappers translate calls to FFTW 2.x functions into the calls of the Intel MKL Fast Fourier Transform interface (FFT interface).

Note that Intel MKL FFT interface operates on both single- and double-precision floating-point data types.

Because of differences between FFTW and Intel MKL FFT functionalities, there are restrictions on using wrappers instead of the FFTW functions. Some FFTW functions have empty wrappers. However, many typical FFTs can be computed using these wrappers.

Refer to [chapter 11 "Fourier Transform Functions"](#), for better understanding the effects from the use of the wrappers.

Wrappers Reference

The section provides a brief reference for the FFTW 2.x C interface. For details please refer to the original FFTW 2.x documentation available at www.fftw.org.

Each FFTW function has its own wrapper. Some of them, which are *not* expressly listed in this section, are empty and do nothing, but they are provided to avoid link errors and satisfy the function calls.

One-dimensional Complex-to-complex FFTs

The following functions compute a one-dimensional complex-to-complex Fast Fourier transform.

```
fftw_plan fftw_create_plan(int n, fftw_direction dir, int flags);  
fftw_plan fftw_create_plan_specific(int n, fftw_direction dir, int flags, fftw_complex  
*in, int istride, fftw_complex *out, int ostride);  
  
void fftw(fftw_plan plan, int howmany, fftw_complex *in, int istride, int idist,  
fftw_complex *out, int ostride, int odist);  
  
void fftw_one(fftw_plan plan, fftw_complex *in , fftw_complex *out);  
  
void fftw_destroy_plan(fftw_plan plan);
```

Multi-dimensional Complex-to-complex FFTs

The following functions compute a multi-dimensional complex-to-complex Fast Fourier transform.

```
fftwnd_plan fftwnd_create_plan(int rank, const int *n, fftw_direction dir, int flags);
fftwnd_plan fftw2d_create_plan(int nx, int ny, fftw_direction dir, int flags);
fftwnd_plan fftw3d_create_plan(int nx, int ny, int nz, fftw_direction dir, int flags);
fftwnd_plan fftwnd_create_plan_specific(int rank, const int *n, fftw_direction dir, int flags,
fftw_complex *in, int istride, fftw_complex *out, int ostride);
fftwnd_plan fftw2d_create_plan_specific(int nx, int ny, fftw_direction dir, int flags,
fftw_complex *in, int istride, fftw_complex *out, int ostride);
fftwnd_plan fftw3d_create_plan_specific(int nx, int ny, int nz, fftw_direction dir, int flags,
fftw_complex *in, int istride, fftw_complex *out, int ostride);

void fftwnd(fftwnd_plan plan, int howmany, fftw_complex *in, int istride, int idist,
fftw_complex *out, int ostride, int odist);

void fftwnd_one(fftwnd_plan plan, fftw_complex *in, fftw_complex *out);

void fftwnd_destroy_plan(fftwnd_plan plan);
```

One-dimensional Real-to-half-complex/Half-complex-to-real FFTs

Half-complex representation of a conjugate-even symmetric vector of size N in a real array of the same size N consists of $N/2+1$ real parts of the elements of the vector followed by non-zero imaginary parts in the reverse order. Because the Intel MKL FFT interface does not currently support this representation, all wrappers of this kind are empty and do nothing.

Nevertheless, you can perform one-dimensional real-to-complex and complex-to-real transforms using `rfftwnd` functions with `rank=1`.

void rfftwnd_real_to_complex(rfftwnd_plan plan, int howmany, fftw_real *in, int istride, int idist,
fftw_complex *out, int ostride, int odist);

void rfftwnd_complex_to_real(rfftwnd_plan plan, int howmany, fftw_complex *in, int istride, int idist,
fftw_real *out, int ostride, int odist);

void rfftwnd_one_real_to_complex(rfftwnd_plan plan, fftw_real *in, fftw_complex *out);
```

```
void rfftwnd_one_complex_to_real(rfftwnd_plan plan, fftw_complex *in, fftw_real *out);
void rfftwnd_destroy_plan(rfftwnd_plan plan);
```

Multi-threaded FFTW

This section discusses multi-threaded FFTW wrappers only. MPI FFTW wrappers, available only with Intel MKL for the Linux* and Windows* operating systems, are described in [section "MPI FFTW Wrappers"](#).

Unlike the original FFTW interface, every computational function in the FFTW2 interface to Intel MKL provides multithreaded computation by default, with the maximum number of threads permitted in FFT functions (see "Techniques to Set the Number of Threads" in *Intel MKL User's Guide*). To limit the number of threads, call the threaded FFTW computational functions:

```
void fftw_threads(int nthreads, fftw_plan plan, int howmany, fftw_complex *in, int
istride, int idist, fftw_complex *out, int ostride, int odist);
void fftw_threads_one(int nthreads, rfftwnd_plan plan, fftw_complex *in, fftw_complex
*out);
...
void rfftwnd_threads_real_to_complex( int nthreads, rfftwnd_plan plan, int howmany,
fftw_real *in, int istride, int idist, fftw_complex *out, int ostride, int odist);
```

Compared to its non-threaded counterpart, every threaded computational function has `threads_` as the second part of its name and additional first parameter `nthreads`. Set the `nthreads` parameter to the thread limit to ensure that the computation requires at most that number of threads.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

FFTW Support Functions

The FFTW wrappers provide memory allocation functions to be used with FFTW:

```
void* fftw_malloc(size_t n);
void fftw_free(void* x);
```

The `fftw_malloc` wrapper aligns the memory on a 16-byte boundary.

If `fftw_malloc` fails to allocate memory, it aborts the application. To override this behavior, set a global variable `fftw_malloc_hook` and optionally the complementary variable `fftw_free_hook`:

```
void (*fftw_malloc_hook) (size_t n);
void (*fftw_free_hook) (void *p);
```

The wrappers use the function `fftw_die` to abort the application in cases when a caller cannot be informed of an error otherwise (for example, in computational functions that return `void`). To override this behavior, set a global variable `fftw_die_hook`:

```
void (*fftw_die_hook) (const char *error_string);
void fftw_die(const char *s);
```

Limitations of the FFTW2 Interface to Intel MKL

The FFTW2 wrappers implement the functionality of only those FFTW functions that Intel MKL can reasonably support. Other functions are provided as no-operation functions, whose only purpose is to satisfy link-time symbol resolution. Specifically, no-operation functions include:

- Real-to-half-complex and respective backward transforms
- Print plan functions
- Functions for importing/exporting/forgetting wisdom
- Most of the FFTW functions not covered by the original FFTW2 documentation

Because the Intel MKL implementation of FFTW2 wrappers does not use plan and plan node structures declared in `fftw.h`, the behavior of an application that relies on the internals of the plan structures defined in that header file is undefined.

FFTW2 wrappers define plan as a set of attributes, such as strides, used to commit the Intel MKL FFT descriptor structure. If an FFTW2 computational function is called with attributes different from those recorded in the plan, the function attempts to adjust the attributes of the plan and recommit the descriptor. So, repeated calls of a computational function with the same plan but different strides, distances, and other parameters may be performance inefficient.

Plan creation functions disregard most planner flags passed through the `flags` parameter. These functions take into account only the following values of `flags`:

- `FFTW_IN_PLACE`

If this value of `flags` is supplied, the plan is marked so that computational functions using that plan ignore the parameters related to output (`out`, `ostride`, and `odist`). Unlike the original FFTW interface, the wrappers never use the `out` parameter as a scratch space for in-place transforms.

- `FFTW_THREADSAFE`

If this value of `flags` is supplied, the plan is marked read-only. An attempt to change attributes of a read-only plan aborts the application.

FFTW wrappers are generally not thread safe. Therefore, do not use the same plan in parallel user threads simultaneously.

Installation

Wrappers are delivered as source code, which you must compile to build the wrapper library. Then you can substitute the wrapper and Intel MKL libraries for the FFTW library. The source code for the wrappers, makefiles, and files with lists of wrappers are located in the `.\interfaces\fftw2xc` subdirectory in the Intel MKL directory.

Creating the Wrapper Library

Two header files are used to compile the C wrapper library: `fftw2_mkl.h` and `fftw.h`. The `fftw2_mkl.h` file is located in the `.\interfaces\fftw2xc\wrappers` subdirectory in the Intel MKL directory.

The file `fftw.h`, used to compile libraries and located in the `.\include\fftw` subdirectory in the Intel MKL directory, slightly differs from the original FFTW (www.fftw.org) header file `fftw.h`.

The source code for the wrappers, makefiles, and files with lists of functions are located in the `.\interfaces\fftw2xc` subdirectory in the Intel MKL directory.

A wrapper library contains wrappers for complex and real transforms in a serial and multi-threaded mode for double- or single-precision floating-point data types. A makefile parameter manages the data type.

Parameters of a makefile also specify the platform (required), compiler, and data precision. The makefile comment heading provides the exact description of these parameters.

To build the library, run the `make` command on Linux* OS and OS X* or the `nmake` command on Windows* OS with appropriate parameters.

For example, on Linux OS the command

```
make libintel64
```

builds a double-precision wrapper library for Intel® 64 architecture based applications using the Intel® C++ Compiler or the Intel® Fortran Compiler (Compilers and data precision are chosen by default.)

Each makefile creates the library in the directory with Intel MKL libraries corresponding to the platform used. For example, `./lib/ia32` (on Linux OS and OS X) or `./lib\ia32` (on Windows* OS).

In the names of a wrapper library, the suffix corresponds to the compiler used and the letter preceding the underscore is "c" for the C programming language.

For example,

```
fftw2xc_intel.lib (on Windows OS); libfftw2xc_intel.a (on Linux OS and OS X);
```

```
fftw2xc_ms.lib (on Windows OS); libfftw2xc_gnu.a (on Linux OS and OS X).
```

Application Assembling

Use the necessary original FFTW (www.fftw.org) header files without any modifications. Use the created wrapper library and the Intel MKL library instead of the FFTW library.

Running Examples

Intel MKL provides examples to demonstrate how to use the MPI FFTW wrapper library. The source code for the examples, makefiles used to run them, and files with lists of examples are located in the `./examples\fftw2xc` subdirectory in the Intel MKL directory. To build examples, several additional files are needed: `fftw.h`, `fftw_threads.h`, `rfftw.h`, and `rfftw_threads.h`. These files are distributed with permission from FFTW and are available in `./include\fftw`. The original files can also be found in FFTW 2.1.5 at <http://www.fftw.org/download.html>.

An example makefile uses the `function` parameter in addition to the parameters of the corresponding wrapper library makefile (see [Creating a Wrapper Library](#)). The makefile comment heading provides the exact description of these parameters.

An example makefile normally invokes examples. However, if the appropriate wrapper library is not yet created, the makefile first builds the library the same way as the wrapper library makefile does and then proceeds to examples.

If the parameter `function=<example_name>` is defined, only the specified example runs. Otherwise, all examples from the appropriate subdirectory run. The subdirectory `./_results` is created, and the results are stored there in the `<example_name>.res` files.

Optimization Notice

Intel's compilers may or may not optimize to the same degree for non-Intel microprocessors for optimizations that are not unique to Intel microprocessors. These optimizations include SSE2, SSE3, and SSSE3 instruction sets and other optimizations. Intel does not guarantee the availability, functionality, or effectiveness of any optimization on microprocessors not manufactured by Intel. Microprocessor-dependent optimizations in this product are intended for use with Intel microprocessors. Certain optimizations not specific to Intel microarchitecture are reserved for Intel microprocessors. Please refer to the applicable product User and Reference Guides for more information regarding the specific instruction sets covered by this notice.

Notice revision #20110804

MPI FFTW Wrappers

MPI FFTW wrappers for FFTW 2 are available only with Intel® MKL for the Linux* and Windows* operating systems.

MPI FFTW Wrappers Reference

The section provides a reference for MPI FFTW C interface.

Complex MPI FFTW

Complex One-dimensional MPI FFTW Transforms

```
fftw_mpi_plan fftw_mpi_create_plan(MPI_Comm comm, int n, fftw_direction dir, int flags);

void fftw_mpi(fftw_mpi_plan p, int n_fields, fftw_complex *local_data, fftw_complex *work);

void fftw_mpi_local_sizes(fftw_mpi_plan p, int *local_n, int *local_start, int *local_n_after_transform, int *local_start_after_transform, int *total_local_size);

void fftw_mpi_destroy_plan(fftw_mpi_plan plan);
```

Argument restrictions:

- Supported values of *flags* are FFTW_ESTIMATE, FFTW_MEASURE, FFTW_SCRAMBLLED_INPUT and FFTW_SCRAMBLLED_OUTPUT. The same algorithm corresponds to all these values of the flags parameter. If any other *flags* value is supplied, the wrapper library reports an error '*CDFT error in wrapper: unknown flags*'.
- The only supported value of *n_fields* is 1.

Complex Multi-dimensional MPI FFTW Transforms

```
fftwnd_mpi_plan fftw2d_mpi_create_plan(MPI_Comm comm, int nx, int ny, fftw_direction dir, int flags);

fftwnd_mpi_plan fftw3d_mpi_create_plan(MPI_Comm comm, int nx, int ny, int nz, fftw_direction dir, int flags);

fftwnd_mpi_plan fftwnd_mpi_create_plan(MPI_Comm comm, int dim, int *n, fftw_direction dir, int flags);

void fftwnd_mpi(fftwnd_mpi_plan p, int n_fields, fftw_complex *local_data, fftw_complex *work, fftwnd_mpi_output_order output_order);

void fftwnd_mpi_local_sizes(fftwnd_mpi_plan p, int *local_nx, int *local_x_start, int *local_ny_after_transpose, int *local_y_start_after_transpose, int *total_local_size);

void fftwnd_mpi_destroy_plan(fftwnd_mpi_plan plan);
```

Argument restrictions:

- Supported values of *flags* are FFTW_ESTIMATE and FFTW_MEASURE. If any other value of *flags* is supplied, the wrapper library reports an error '*CDFT error in wrapper: unknown flags*'.
- The only supported value of *n_fields* is 1.

Real MPI FFTW

Real-to-Complex MPI FFTW Transforms

```
rfftwnd_mpi_plan rfftw2d_mpi_create_plan(MPI_Comm comm, int nx, int ny, fftw_direction dir, int flags);

rfftwnd_mpi_plan rfftw3d_mpi_create_plan(MPI_Comm comm, int nx, int ny, int nz, fftw_direction dir, int flags);
```

```

rfftwnd_mpi_plan rfftwnd_mpi_create_plan(MPI_Comm comm, int dim, int *n, fftw_direction
dir, int flags);

void rfftwnd_mpi(rfftwnd_mpi_plan p, int n_fields, fftw_real *local_data, fftw_real
*work, fftwnd_mpi_output_order output_order);

void rfftwnd_mpi_local_sizes(rfftwnd_mpi_plan p, int *local_nx, int *local_x_start, int
*local_ny_after_transpose, int *local_y_start_after_transpose, int *total_local_size);

void rfftwnd_mpi_destroy_plan(rfftwnd_mpi_plan plan);

```

Argument restrictions:

- Supported values of *flags* are FFTW_ESTIMATE and FFTW_MEASURE. If any other value of *flags* is supplied, the wrapper library reports an error 'CDFT error in wrapper: unknown flags'.
- The only supported value of *n_fields* is 1.

-
- Function *rfftwnd_mpi_create_plan* can be used for both one-dimensional and multi-dimensional transforms.
 - Both values of the *output_order* parameter are supported: FFTW_NORMAL_ORDER and FFTW_TRANSPOSED_ORDER.
-

Creating MPI FFTW Wrapper Library

The source code for the wrappers, makefiles, and files with lists of wrappers are located in the `.\interfaces\fftw2x_cdft` subdirectory in the Intel MKL directory.

A wrapper library contains C wrappers for Complex One-dimensional MPI FFTW Transforms and Complex Multi-dimensional MPI FFTW Transforms. The library also contains empty C wrappers for Real Multi-dimensional MPI FFTW Transforms. For details, see [MPI FFTW Wrappers Reference](#).

Parameters of a makefile specify the platform (required), compiler, and data precision. Specifying the platform is required. The makefile comment heading provides the exact description of these parameters.

To build the library, run the `make` command on Linux* OS and OS X* or the `nmake` command on Windows* OS with appropriate parameters.

For example, on Linux OS the command

```
make libintel64
```

builds a double-precision wrapper library for Intel® 64 architecture based applications using Intel MPI and the Intel® C++ Compiler (compilers and data precision are chosen by default.).

A makefile creates the wrapper library in the directory with the Intel MKL libraries corresponding to the used platform. For example, `./lib/ia32` (on Linux OS) or `.\lib\ia32` (on Windows* OS).

In the wrapper library names, the suffix corresponds to the used data precision. For example,

`fftw2x_cdft_SINGLE.lib` on Windows OS;

`libfftw2x_cdft_DOUBLE.a` on Linux OS.

Application Assembling with MPI FFTW Wrapper Library

Use the necessary original FFTW (www.fftw.org) header files without any modifications. Use the created MPI FFTW wrapper library and the Intel MKL library instead of the FFTW library.

Running Examples

There are some examples that demonstrate how to use the MPI FFTW wrapper library for FFTW2. The source C code for the examples, makefiles used to run them, and files with lists of examples are located in the `.\examples\fftw2x_cdft` subdirectory in the Intel MKL directory. To build examples, one additional file `fftw_mpi.h` is needed. This file is distributed with permission from FFTW and is available in `.\include\fftw`. The original file can also be found in FFTW 2.1.5 at <http://www.fftw.org/download.html>.

Parameters for the example makefiles are described in the makefile comment headings and are similar to the parameters of the wrapper library makefiles (see [Creating MPI FFTW Wrapper Library](#)).

The table below lists examples available in the `.\examples\fftw2x_cdft\source` subdirectory.

Examples of MPI FFTW Wrappers

Source file for the example	Description
<code>wrappers_c1d.c</code>	One-dimensional Complex MPI FFTW transform, using <code>plan = fftw_mpi_create_plan(...)</code>
<code>wrappers_c2d.c</code>	Two-dimensional Complex MPI FFTW transform, using <code>plan = fftw2d_mpi_create_plan(...)</code>
<code>wrappers_c3d.c</code>	Three-dimensional Complex MPI FFTW transform, using <code>plan = fftw3d_mpi_create_plan(...)</code>
<code>wrappers_c4d.c</code>	Four-dimensional Complex MPI FFTW transform, using <code>plan = fftwnd_mpi_create_plan(...)</code>
<code>wrappers_r1d.c</code>	One-dimensional Real MPI FFTW transform, using <code>plan = rfftw_mpi_create_plan(...)</code>
<code>wrappers_r2d.c</code>	Two-dimensional Real MPI FFTW transform, using <code>plan = rfftw2d_mpi_create_plan(...)</code>
<code>wrappers_r3d.c</code>	Three-dimensional Real MPI FFTW transform, using <code>plan = rfftw3d_mpi_create_plan(...)</code>
<code>wrappers_r4d.c</code>	Four-dimensional Real MPI FFTW transform, using <code>plan = rffwnd_mpi_create_plan(...)</code>

FFTW3 Interface to Intel® Math Kernel Library

This section describes a collection of FFTW3 wrappers to Intel MKL. The wrappers translate calls of FFTW3 functions to the calls of the Intel MKL Fourier transform (FFT) or Trigonometric Transform (TT) functions. The purpose of FFTW3 wrappers is to enable developers whose programs currently use the FFTW3 library to gain performance with the Intel MKL Fourier transforms without changing the program source code.

The FFTW3 wrappers provide a limited functionality compared to the original FFTW 3.x library, because of differences between FFTW and Intel MKL FFT and TT functionality. This section describes limitations of the FFTW3 wrappers and hints for their usage. Nevertheless, many typical FFT tasks can be performed using the FFTW3 wrappers to Intel MKL.

The FFTW3 wrappers are integrated in Intel MKL. The only change required to use Intel MKL through the FFTW3 wrappers is to link your application using FFTW3 against Intel MKL.

A reference implementation of the FFTW3 wrappers is also provided in open source. You can find it in the `interfaces` directory of the Intel MKL distribution. You can use the reference implementation to create your own wrapper library (see [Building Your Own Wrapper Library](#))

See also these resources:

Intel MKL Release Notes for the version of the FFTW3 library supported by the wrappers.

www.fftw.org	for a description of the FFTW interface.
Fourier Transform Functions	for a description of the Intel MKL FFT interface.
Trigonometric Transform Routines	for a description of Intel MKL TT interface.

Using FFTW3 Wrappers

The FFTW3 wrappers are a set of functions and data structures depending on one another. The wrappers are not designed to provide the interface on a function-per-function basis. Some FFTW3 wrapper functions are empty and do nothing, but they are present to avoid link errors and satisfy function calls.

This manual does not list the declarations of the functions that the FFTW3 wrappers provide (you can find the declarations in the `fftw3.h` header file). Instead, this section comments particular limitations of the wrappers and provides usage hints:

- The FFTW3 wrappers do not support long double precision because Intel MKL FFT functions operate only on single- and double-precision floating-point data types (`float` and `double`, respectively). Therefore the functions with prefix `fftwl_`, supporting the `long double` data type, are not provided.
- The wrappers provide equivalent implementation for double- and single-precision functions (those with prefixes `fftw_` and `fftwf_`, respectively). So, all these comments equally apply to the double- and single-precision functions and will refer to functions with prefix `fftw_`, that is, double-precision functions, for brevity.
- The FFTW3 interface that the wrappers provide is defined in the `fftw3.h` header file. This file is borrowed from the FFTW3.x package and distributed within Intel MKL with permission. Additionally, the `fftw3_mkl.h` header file defines supporting structures and supplementary constants and macros.
- Actual functionality of the plan creation wrappers is implemented in `guru64` set of functions. Basic interface, advanced interface, and `guru` interface plan creation functions call the `guru64` interface functions. So, all types of the FFTW3 plan creation interface in the wrappers are functional.
- Plan creation functions may return a `NULL` plan, indicating that the functionality is not supported. So, please carefully check the result returned by plan creation functions in your application. In particular, the following problems return a `NULL` plan:
 - `c2r` and `r2c` problems with a split storage of complex data.
 - `r2r` problems with `kind` values `FFTW_R2HC`, `FFTW_HC2R`, and `FFTW_DHT`. The only supported `r2r` kinds are even/odd DFTs (sine/cosine transforms).
 - Multidimensional `r2r` transforms.
 - Transforms of multidimensional vectors. That is, the only supported values for parameter `howmany_rank` in `guru` and `guru64` plan creation functions are 0 and 1.
 - Multidimensional transforms with `rank > MKL_MAXRANK`.
- The `MKL_RODFT00` value of the `kind` parameter is introduced by the FFTW3 wrappers. For better performance, you are strongly encouraged to use this value rather than `FFTW_RODFT00`. To use this `kind` value, provide an extra first element equal to 0.0 for the input/output vectors. Consider the following example:

```
plan1 = fftw_plan_r2r_1d(n, in1, out1, FFTW_RODFT00, FFTW_ESTIMATE);
plan2 = fftw_plan_r2r_1d(n, in2, out2, MKL_RODFT00, FFTW_ESTIMATE);
```

Both plans perform the same transform, except that the `in2/out2` arrays have one extra zero element at location 0. For example, if `n=3`, `in1={x,y,z}` and `out1={u,v,w}`, then `in2={0,x,y,z}` and `out2={0,u,v,w}`.

- The `flags` parameter in plan creation functions is always ignored. The same algorithm is used regardless of the value of this parameter. In particular, `flags` values `FFTW_ESTIMATE`, `FFTW_MEASURE`, etc. have no effect.
- For multithreaded plans, use normal sequence of calls to the `fftw_init_threads()` and `fftw_plan_with_nthreads()` functions (refer to FFTW documentation).
- Memory allocation function `fftw_malloc` returns memory aligned at a 16-byte boundary. You must free the memory with `fftw_free`.

- The FFTW3 wrappers to Intel MKL use the 32-bit `int` type in both LP64 and ILP64 interfaces of Intel MKL. Use `guru64` FFTW3 interfaces for 64-bit sizes.
- The wrappers typically indicate a problem by returning a `NULL` plan. In a few cases, the wrappers may report a descriptive message of the problem detected. By default the reporting is turned off. To turn it on, set variable `fftw3_mkl.verbose` to a non-zero value, for example:

```
#include "fftw3.h"
#include "fftw3_mkl.h"
fftw3_mkl.verbose = 0;
plan = fftw_plan_r2r(...);
```

- The following functions are empty:
 - For saving, loading, and printing plans
 - For saving and loading wisdom
 - For estimating arithmetic cost of the transforms.
- Do not use macro `FFTW_DLL` with the FFTW3 wrappers to Intel MKL.
- Do not use negative stride values. Though FFTW3 wrappers support negative strides in the part of advanced and guru FFTW interface, the underlying implementation does not.

Building Your Own Wrapper Library

The FFTW3 wrappers to Intel MKL are delivered both integrated in Intel MKL and as source code, which can be compiled to build a standalone wrapper library with exactly the same functionality. Normally you do not need to build the wrappers yourself.

The source code for the wrappers, makefiles, and files with lists of functions are located in the `.` \interfaces\fftw3xc subdirectory in the Intel MKL directory.

To build the wrappers,

1. Change the current directory to the wrapper directory
2. Run the `make` command on Linux* OS and OS X* or the `nmake` command on Windows* OS with a required target and optionally several parameters.

The target `libia32` or `libintel64` defines the platform architecture, and the other parameters specify the compiler, size of the default integer type, and placement of the resulting wrapper library. You can find a detailed and up-to-date description of the parameters in the makefile.

In the following example, the `make` command is used to build the FFTW3 C wrappers to Intel MKL for use from the GNU `gcc`* compiler on Linux OS based on Intel® 64 architecture:

```
cd interfaces/fftw3xc
make libintel64 compiler=gnu INSTALL_DIR=/my/path
```

This command builds the wrapper library and places the result, named `libfftw3xc_gnu.a`, into the `/my/path` directory. The name of the resulting library is composed of the name of the compiler used and may be changed by an optional parameter `INSTALL_LIBNAME`.

Building an Application

Normally, the only change needed to build your application with FFTW3 wrappers replacing original FFTW library is to add Intel MKL at the link stage (see section *"Linking Your Application with Intel® Math Kernel Library" in the Intel MKL User's Guide*).

If you recompile your application, add subdirectory `include\fftw` to the search path for header files to avoid FFTW3 version conflicts.

Sometimes, you may have to modify your application according to the following recommendations:

- The application requires

```
#include "fftw3.h",
```

which it probably already includes.

- The application does not require

```
#include "mkl_dfti.h" .
```

- The application does not require

```
#include "fftw3_mkl.h" .
```

It is required only in case you want to use the `MKL_RODFT00` constant.

- If the application does not check whether a `NULL` plan is returned by plan creation functions, this check must be added, because the FFTW3 to Intel MKL wrappers do not provide 100% of FFTW3 functionality.

Running Examples

There are some examples that demonstrate how to use the wrapper library. The source code for the examples, makefiles used to run them, and files with lists of examples are located in the `.\examples\fftw3xc` subdirectory in the Intel MKL directory.

Parameters of the example makefiles are similar to the parameters of the wrapper library makefiles. Example makefiles normally build and invoke the examples. If the parameter `function=<example_name>` is defined, then only the specified example will run. Otherwise, all examples will be executed. Results of running the examples are saved in subdirectory `._results` in files with extension `.res`.

For detailed information about options for the example makefile, refer to the makefile.

MPI FFTW Wrappers

This section describes a collection of MPI FFTW wrappers to Intel® MKL.

MPI FFTW wrappers are available only with Intel MKL for the Linux* and Windows* operating systems.

These wrappers translate calls of MPI FFTW functions to the calls of the Intel MKL cluster Fourier transform (CFFT) functions. The purpose of the wrappers is to enable users of MPI FFTW functions improve performance of the applications without changing the program source code.

Although the MPI FFTW wrappers provide less functionality than the original FFTW3 because of differences between MPI FFTW and Intel MKL CFFT, the wrappers cover many typical CFFT use cases.

The MPI FFTW wrappers are provided as source code. To use the wrappers, you need to build your own wrapper library (see [Building Your Own Wrapper Library](#)).

See also these resources:

Intel MKL Release Notes for the version of the FFTW3 library supported by the wrappers.

www.fftw.org for a description of the MPI FFTW interface.

[Cluster FFT Functions](#) for a description of the Intel MKL CFFT interface.

Building Your Own Wrapper Library

The MPI FFTW wrappers for FFTW3 are delivered as source code, which can be compiled to build a wrapper library.

The source code for the wrappers, makefiles, and files with lists of functions are located in subdirectory `.\interfaces\fftw3x_cdft` in the Intel MKL directory.

To build the wrappers,

1. Change the current directory to the wrapper directory
2. Run the `make` command on Linux* OS or the `nmake` command on Windows* OS with a required target and optionally several parameters.

The target `libia32` or `libintel64` defines the platform architecture, and the other parameters specify the compiler, size of the default `INTEGER` type, as well as the name and placement of the resulting wrapper library. You can find a detailed and up-to-date description of the parameters in the makefile.

In the following example, the `make` command is used to build the MPI FFTW wrappers to Intel MKL for use from the GNU C compiler on Linux OS based on Intel® 64 architecture:

```
cd interfaces/fftw3x_cdft
make libintel64 compiler=gcc mpi=openmpi INSTALL_DIR=/my/path
```

This command builds the wrapper library using the GNU gcc compiler so that the final executable can use Open MPI, and places the result, named `libfftw3x_cdft_DOUBLE.a`, into directory `/my/path`.

Building an Application

Normally, the only change needed to build your application with MPI FFTW wrappers replacing original FFTW3 library is to add Intel MKL and the wrapper library at the link stage (see section "*Linking Your Application with Intel® Math Kernel Library*" in the *Intel MKL User's Guide*).

When you are recompiling your application, add subdirectory `include\fftw` to the search path for header files to avoid FFTW3 version conflicts.

Running Examples

There are some examples that demonstrate how to use the MPI FFTW wrapper library for FFTW3. The source code for the examples, makefiles used to run them, and files with lists of examples are located in the `.\examples\fftw3x_cdft` subdirectory in the Intel MKL directory.

Parameters of the example makefiles are similar to the parameters of the wrapper library makefiles. Example makefiles normally build and invoke the examples. Results of running the examples are saved in subdirectory `.\_results` in files with extension `.res`.

For detailed information about options for the example makefile, refer to the makefile.

Code Examples

This appendix presents code examples of using some Intel MKL routines and functions.

Please refer to respective chapters in the manual for detailed descriptions of function parameters and operation.

BLAS Code Examples

Example. Using BLAS Level 1 Function

The following example illustrates a call to the BLAS Level 1 function `sdot`. This function performs a vector-vector operation of computing a scalar product of two single-precision real vectors *x* and *y*.

Parameters

n Specifies the number of elements in vectors *x* and *y*.

incx Specifies the increment for the elements of *x*.

incy Specifies the increment for the elements of *y*.

```
#include <stdio.h>
#include <stdlib.h>

#include "mkl_example.h"

int main()
{
    MKL_INT  n, incx, incy, i;
    float    *x, *y;
    float    res;
    MKL_INT  len_x, len_y;

    n = 5;
    incx = 2;
    incy = 1;

    len_x = 1+(n-1)*abs(incx);
    len_y = 1+(n-1)*abs(incy);
    x = (float *)calloc( len_x, sizeof( float ) );
    y = (float *)calloc( len_y, sizeof( float ) );
    if( x == NULL || y == NULL ) {
        printf( "\n Can't allocate memory for arrays\n");
        return 1;
    }

    for ( i = 0; i < n; i++) {
        x[i*abs(incx)] = 2.0;
        y[i*abs(incy)] = 1.0;
    }

    res = cblas_sdot(n, x, incx, y, incy);
```

```
printf("\n      SDOT = %7.3f", res);

free(x);
free(y);

return 0;
}
```

As a result of this program execution, the following line is printed:

SDOT = 10.000

Example. Using BLAS Level 1 Routine

The following example illustrates a call to the BLAS Level 1 routine `scopy`. This routine performs a vector-vector operation of copying a single-precision real vector *x* to a vector *y*.

Parameters

<i>n</i>	Specifies the number of elements in vectors <i>x</i> and <i>y</i> .
<i>incx</i>	Specifies the increment for the elements of <i>x</i> .
<i>incy</i>	Specifies the increment for the elements of <i>y</i> .

```
#include <stdio.h>
#include <stdlib.h>

#include "mkl_example.h"

int main()
{
    MKL_INT  n, incx, incy, i;
    float    *x, *y;
    MKL_INT  len_x, len_y;
    n = 3;
    incx = 3;
    incy = 1;

    len_x = 10;
    len_y = 10;
    x = (float *)calloc( len_x, sizeof( float ) );
    y = (float *)calloc( len_y, sizeof( float ) );
    if( x == NULL || y == NULL ) {
        printf( "\n Can't allocate memory for arrays\n");
        return 1;
    }
    for (i = 0; i < 10; i++) {
        x[i] = i + 1;
    }

    cblas_scopy(n, x, incx, y, incy);

/*      Print output data                                */

    printf("\n\n      OUTPUT DATA");
    PrintVectorS(FULLPRINT, n, y, incy, "Y");

    free(x);
```

```

    free(y);
    return 0;
}

```

As a result of this program execution, the following line is printed:

Y = 1.00000 4.00000 7.00000

Example. Using BLAS Level 2 Routine

The following example illustrates a call to the BLAS Level 2 routine `sger`. This routine performs a matrix-vector operation

```
a := alpha*x*y' + a.
```

Parameters

<i>alpha</i>	Specifies a scalar <i>alpha</i> .
<i>x</i>	<i>m</i> -element vector.
<i>y</i>	<i>n</i> -element vector.
<i>a</i>	<i>m</i> -by- <i>n</i> matrix.

```

#include <stdio.h>
#include <stdlib.h>

#include "mkl_example.h"

int main()
{
    MKL_INT      m, n, lda, incx, incy, i, j;
    MKL_INT      rmaxa, cmaxa;
    float        alpha;
    float        *a, *x, *y;
    CBLAS_LAYOUT layout;
    MKL_INT      len_x, len_y;

    m = 2;
    n = 3;
    lda = 5;
    incx = 2;
    incy = 1;
    alpha = 0.5;

    layout = CblasRowMajor;

    len_x = 10;
    len_y = 10;
    rmaxa = m + 1;
    cmaxa = n;
    a = (float *)calloc( rmaxa*cmaxa, sizeof(float) );
    x = (float *)calloc( len_x, sizeof(float) );
    y = (float *)calloc( len_y, sizeof(float) );
    if( a == NULL || x == NULL || y == NULL ) {
        printf( "\n Can't allocate memory for arrays\n");
        return 1;
    }
    if( layout == CblasRowMajor )
        lda=cmaxa;
    else
        lda=rmaxa;

```

```

for (i = 0; i < 10; i++) {
    x[i] = 1.0;
    y[i] = 1.0;
}

for (i = 0; i < m; i++) {
    for (j = 0; j < n; j++) {
        a[i + j*lda] = j + 1;
    }
}

cblas_sger(layout, m, n, alpha, x, incx, y, incy, a, lda);

PrintArrayS(&layout, FULLPRINT, GENERAL_MATRIX, &m, &n, a, &lda, "A");

free(a);
free(x);
free(y);

return 0;
}

```

As a result of this program execution, matrix *a* is printed as follows:

Matrix A:

```

1.50000 2.50000 3.50000
1.50000 2.50000 3.50000

```

Example. Using BLAS Level 3 Routine

The following example illustrates a call to the BLAS Level 3 routine `ssymm`. This routine performs a matrix-matrix operation

```
c := alpha*a*b' + beta*c.
```

Parameters

<i>alpha</i>	Specifies a scalar <i>alpha</i> .
<i>beta</i>	Specifies a scalar <i>beta</i> .
<i>a</i>	Symmetric matrix
<i>b</i>	<i>m</i> -by- <i>n</i> matrix
<i>c</i>	<i>m</i> -by- <i>n</i> matrix

```

#include <stdio.h>
#include <stdlib.h>

#include "mkl_example.h"

int main(int argc, char *argv[])
{
    MKL_INT      m, n, i, j;
    MKL_INT      lda, ldb, ldc;
    MKL_INT      rmaxa, cmaxa, rmaxb, cmaxb, rmaxc, cmaxc;
    float        alpha, beta;
    float        *a, *b, *c;
    CBLAS_LAYOUT layout;

```

```

CBLAS_SIDE      side;
CBLAS_UPLO      upto;
MKL_INT         ma, na, typeA;
uplo = 'u';
side = 'l';
layout = CblasRowMajor;
m = 3;
n = 2;
lda = 3;
ldb = 3;
ldc = 3;
alpha = 0.5;
beta = 2.0;

if( side == CblasLeft ) {
    rmaxa = m + 1;
    cmaxa = m;
    ma    = m;
    na    = m;
} else {
    rmaxa = n + 1;
    cmaxa = n;
    ma    = n;
    na    = n;
}
rmaxb = m + 1;
cmaxb = n;
rmaxc = m + 1;
cmaxc = n;
a = (float *)calloc( rmaxa*cmaxa, sizeof(float) );
b = (float *)calloc( rmaxb*cmaxb, sizeof(float) );
c = (float *)calloc( rmaxc*cmaxc, sizeof(float) );
if ( a == NULL || b == NULL || c == NULL ) {
    printf("\n Can't allocate memory arrays");
    return 1;
}

if( layout == CblasRowMajor ) {
    lda=cmaxa;
    ldb=cmaxb;
    ldc=cmaxc;
} else {
    lda=rmaxa;
    ldb=rmaxb;
    ldc=rmaxc;
}

if (uplo == CblasUpper) typeA = UPPER_MATRIX;
else                    typeA = LOWER_MATRIX;
for (i = 0; i < m; i++) {
    for (j = 0; j < m; j++) {
        a[i + j*lda] = 1.0;
    }
}

for (i = 0; i < m; i++) {
    for (j = 0; j < n; j++) {
        c[i + j*ldc] = 1.0;
        b[i + j*ldb] = 2.0;
    }
}

cblas_ssymm(layout, side, upto, m, n, alpha, a, lda,

```

```

        b, ldb, beta, c, ldc);

printf("\n\n      OUTPUT DATA");
PrintArrayS(&layout, FULLPRINT, GENERAL_MATRIX, &m, &n, c, &ldc, "C");

free(a);
free(b);
free(c);

return 0;
}

```

As a result of this program execution, matrix *c* is printed as follows:

Matrix C:

```

5.00000 5.00000
5.00000 5.00000
5.00000 5.00000

```

The following example illustrates a call from a C program to the Fortran version of the complex BLAS Level 1 function `zdotc()`. This function computes the dot product of two double-precision complex vectors.

Example. Calling a Complex BLAS Level 1 Function from C

In this example, the complex dot product is returned in the structure *c*.

```

#include <stdio>
#include "mkl_blas.h"
#define N 5
void main()
{
    int n, inca = 1, incb = 1, i;
    MKL_Complex16 a[N], b[N], c;
    void zdotc();
    n = N;
    for( i = 0; i < n; i++ ){
        a[i].real = (double)i; a[i].imag = (double)i * 2.0;
        b[i].real = (double)(n - i); b[i].imag = (double)i * 2.0;
    }
    zdotc( &c, &n, a, &inca, b, &incb );
    printf( "The complex dot product is: ( %6.2f, %6.2f )\n", c.real, c.imag );
}

```

NOTE

Instead of calling BLAS directly from C programs, you might wish to use the C interface to the Basic Linear Algebra Subprograms (CBLAS) implemented in Intel® MKL. See [C Interface Conventions](#) for more information.

Fourier Transform Functions Code Examples

This section presents code examples for functions described in the “[FFT Functions](#)” and “[Cluster FFT Functions](#)” sections in the “Fourier Transform Functions” chapter. The examples are grouped in subsections

- [Examples for FFT Functions](#), including [Examples of Using Multi-Threading for FFT Computation](#)
- [Examples for Cluster FFT Functions](#)
- [Auxiliary data transformations](#).

FFT Code Examples

This section presents examples of using the FFT interface functions described in “[Fourier Transform Functions](#)” chapter.

Here are the examples of two one-dimensional computations. These examples use the default settings for all of the configuration parameters, which are specified in “[Configuration Settings](#)”.

One-dimensional In-place FFT

```
/* C example, float _Complex is defined in C9X */
#include "mkl_dfti.h"
float _Complex x[32];
float y[32];
DFTI_DESCRIPTOR_HANDLE my_desc1_handle;
DFTI_DESCRIPTOR_HANDLE my_desc2_handle;
MKL_LONG status;
//...put input data into x[0],...,x[31]; y[0],...,y[31]
status = DftiCreateDescriptor( &my_desc1_handle, DFTI_SINGLE,
    DFTI_COMPLEX, 1, 32);
status = DftiCommitDescriptor( my_desc1_handle );
status = DftiComputeForward( my_desc1_handle, x);
status = DftiFreeDescriptor(&my_desc1_handle);
/* result is x[0], ..., x[31]*/
status = DftiCreateDescriptor( &my_desc2_handle, DFTI_SINGLE,
    DFTI_REAL, 1, 32);
status = DftiCommitDescriptor( my_desc2_handle);
status = DftiComputeForward( my_desc2_handle, y);
status = DftiFreeDescriptor(&my_desc2_handle);
/* result is given in CCS format*/
```

One-dimensional Out-of-place FFT

```
/* C example, float _Complex is defined in C9X */
#include "mkl_dfti.h"
float _Complex x_in[32];
float _Complex x_out[32];
float y_in[32];
float y_out[32];

DFTI_DESCRIPTOR_HANDLE my_desc1_handle;
DFTI_DESCRIPTOR_HANDLE my_desc2_handle;
MKL_LONG status;
//...put input data into x_in[0],...,x_in[31]; y_in[0],...,y_in[31]
status = DftiCreateDescriptor( &my_desc1_handle, DFTI_SINGLE,
    DFTI_COMPLEX, 1, 32);
status = DftiSetValue( my_desc1_handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE);
status = DftiCommitDescriptor( my_desc1_handle );
status = DftiComputeForward( my_desc1_handle, x_in, x_out);
status = DftiFreeDescriptor(&my_desc1_handle);
/* result is x_out[0], ..., x_out[31]*/
status = DftiCreateDescriptor( &my_desc2_handle, DFTI_SINGLE,
    DFTI_REAL, 1, 32);
Status = DftiSetValue( My_Desc2_Handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE);
status = DftiCommitDescriptor( my_desc2_handle);
status = DftiComputeForward( my_desc2_handle, y_in, y_out);
```

```
status = DftiFreeDescriptor(&my_desc2_handle);
/* result is given by y_out in CCS format*/
```

Two-dimensional FFT

```
/* C99 example */
#include "mkl_dfti.h"
float _Complex x[32][100];
float y[34][102];
DFTI_DESCRIPTOR_HANDLE my_desc1_handle;
DFTI_DESCRIPTOR_HANDLE my_desc2_handle;
MKL_LONG status, l[2];
//...put input data into x[j][k] 0<=j<=31, 0<=k<=99
//...put input data into y[j][k] 0<=j<=31, 0<=k<=99
l[0] = 32; l[1] = 100;
status = DftiCreateDescriptor( &my_desc1_handle, DFTI_SINGLE,
                              DFTI_COMPLEX, 2, l);
status = DftiCommitDescriptor( my_desc1_handle);
status = DftiComputeForward( my_desc1_handle, x);
status = DftiFreeDescriptor(&my_desc1_handle);
/* result is the complex value x[j][k], 0<=j<=31, 0<=k<=99 */
status = DftiCreateDescriptor( &my_desc2_handle, DFTI_SINGLE,
                              DFTI_REAL, 2, l);
status = DftiCommitDescriptor( my_desc2_handle);
status = DftiComputeForward( my_desc2_handle, y);
status = DftiFreeDescriptor(&my_desc2_handle);
/* result is the complex value z(j,k) 0<=j<=31; 0<=k<=99
/* and is stored in CCS format*/
```

The following example demonstrates how you can change the default configuration settings by using the `DftiSetValue` function.

For instance, to preserve the input data after the FFT computation, the configuration of `DFTI_PLACEMENT` should be changed to "not in place" from the default choice of "in place."

The code below illustrates how this can be done:

Changing Default Settings

```
/* C99 example */
#include "mkl_dfti.h"
float _Complex x_in[32], x_out[32];
DFTI_DESCRIPTOR_HANDLE my_desc_handle;
MKL_LONG status;
//...put input data into x_in[j], 0 <= j < 32
status = DftiCreateDescriptor( &my_desc_handle, DFTI_SINGLE,
                              DFTI_COMPLEX, 1, 32);
status = DftiSetValue( my_desc_handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE);
status = DftiCommitDescriptor( my_desc_handle);
status = DftiComputeForward( my_desc_handle, x_in, x_out);
status = DftiFreeDescriptor(&my_desc_handle);
/* result is x_out[0], x_out[1], ..., x_out[31] */
```

Using Status Checking Functions

This example illustrates the use of status checking functions described in [Chapter 11](#).

```
/* C */
DFTI_DESCRIPTOR_HANDLE desc;
MKL_LONG status;
// . . . descriptor creation and other code
status = DftiCommitDescriptor(desc);
if (status && !DftiErrorClass(status,DFTI_NO_ERROR))
{
    printf ('Error: %s\n', DftiErrorMessage(status));
}
```

Computing 2D FFT by One-Dimensional Transforms

Below is an example where a 20-by-40 two-dimensional FFT is computed explicitly using one-dimensional transforms.

```
/* C */
#include "mkl_dfti.h"
float _Complex x[20][40];
MKL_LONG stride[2];
MKL_LONG status;
DFTI_DESCRIPTOR_HANDLE desc_handle_dim1;
DFTI_DESCRIPTOR_HANDLE desc_handle_dim2;
//...
status = DftiCreateDescriptor( &desc_handle_dim1, DFTI_SINGLE,
    DFTI_COMPLEX, 1, 20 );
status = DftiCreateDescriptor( &desc_handle_dim2, DFTI_SINGLE,
    DFTI_COMPLEX, 1, 40 );

/* perform 40 one-dimensional transforms along 1st dimension */
/* note that the 1st dimension data are not unit-stride */
stride[0] = 0; stride[1] = 40;
status = DftiSetValue( desc_handle_dim1, DFTI_NUMBER_OF_TRANSFORMS, 40 );
status = DftiSetValue( desc_handle_dim1, DFTI_INPUT_DISTANCE, 1 );
status = DftiSetValue( desc_handle_dim1, DFTI_OUTPUT_DISTANCE, 1 );
status = DftiSetValue( desc_handle_dim1, DFTI_INPUT_STRIDES, stride );
status = DftiSetValue( desc_handle_dim1, DFTI_OUTPUT_STRIDES, stride );
status = DftiCommitDescriptor( desc_handle_dim1 );
status = DftiComputeForward( desc_handle_dim1, x );
/* perform 20 one-dimensional transforms along 2nd dimension */
/* note that the 2nd dimension is unit stride */
status = DftiSetValue( desc_handle_dim2, DFTI_NUMBER_OF_TRANSFORMS, 20 );
status = DftiSetValue( desc_handle_dim2,
    DFTI_INPUT_DISTANCE, 40 );
status = DftiSetValue( desc_handle_dim2,
    DFTI_OUTPUT_DISTANCE, 40 );
status = DftiCommitDescriptor( desc_handle_dim2 );
status = DftiComputeForward( desc_handle_dim2, x );
status = DftiFreeDescriptor( &desc_handle_dim1 );
status = DftiFreeDescriptor( &desc_handle_dim2 );
```

The following code illustrates real multi-dimensional transforms with CCE format storage of conjugate-even complex matrix. [Example “Three-Dimensional REAL FFT \(C Interface\)”](#) is three-dimensional out-of-place transform in C interface.

Three-Dimensional REAL FFT

```
/* C99 example */
#include "mkl_dfti.h"
float x[32][100][19];
float _Complex y[32][100][10]; /* 10 = 19/2 + 1 */
DFTI_DESCRIPTOR_HANDLE my_desc_handle;
MKL_LONG status, l[3];
MKL_LONG strides_out[4];

//...put input data into x[j][k][s] 0<=j<=31, 0<=k<=99, 0<=s<=18
l[0] = 32; l[1] = 100; l[2] = 19;

strides_out[0] = 0; strides_out[1] = 1000;
strides_out[2] = 10; strides_out[3] = 1;

status = DftiCreateDescriptor( &my_desc_handle, DFTI_SINGLE,
DFTI_REAL, 3, 1 );
status = DftiSetValue(my_desc_handle,
DFTI_CONJUGATE_EVEN_STORAGE, DFTI_COMPLEX_COMPLEX);
status = DftiSetValue( my_desc_handle, DFTI_PLACEMENT, DFTI_NOT_INPLACE );
status = DftiSetValue(my_desc_handle,
DFTI_OUTPUT_STRIDES, strides_out);

status = DftiCommitDescriptor(my_desc_handle);
status = DftiComputeForward(my_desc_handle, x, y);
status = DftiFreeDescriptor(&my_desc_handle);
/* result is the complex value z(j,k,s) 0<=j<=31; 0<=k<=99, 0<=s<=9
and is stored in complex matrix y in CCE format. */
```

Examples of Using OpenMP* Threading for FFT Computation

The following sample program shows how to employ internal OpenMP* threading in Intel MKL for FFT computation.

To specify the number of threads inside Intel MKL, use the following settings:

set MKL_NUM_THREADS = 1 for one-threaded mode;

set MKL_NUM_THREADS = 4 for multi-threaded mode.

Using Intel MKL Internal Threading Mode (C Example)

```
#include "mkl_dfti.h"

int main ()
{
    float x[200][100];
    DFTI_DESCRIPTOR_HANDLE fft;
    MKL_LONG len[2] = {200, 100};
    // initialize x
    DftiCreateDescriptor ( &fft, DFTI_SINGLE, DFTI_REAL, 2, len );
    DftiCommitDescriptor ( fft );
    DftiComputeForward ( fft, x );
    DftiFreeDescriptor ( &fft );
```

```
    return 0;
}
```

The following [Example “Using Parallel Mode with Multiple Descriptors Initialized in a Parallel Region”](#) and [Example “Using Parallel Mode with Multiple Descriptors Initialized in One Thread”](#) illustrate a parallel customer program with each descriptor instance used only in a single thread.

Specify the number of OpenMP threads for [Example “Using Parallel Mode with Multiple Descriptors Initialized in a Parallel Region”](#) like this:

set MKL_NUM_THREADS = 1 for Intel MKL to work in the single-threaded mode (recommended);

set OMP_NUM_THREADS = 4 for the customer program to work in the multi-threaded mode.

Using Parallel Mode with Multiple Descriptors Initialized in a Parallel Region

Note that in this example, the program can be transformed to become single-threaded at the customer level but using parallel mode within Intel MKL. To achieve this, you need to set the parameter

DFTI_NUMBER_OF_TRANSFORMS = 4 and to set the corresponding parameter DFTI_INPUT_DISTANCE = 5000.

```
#include "mkl_dfti.h"
#include <omp.h>
#define ARRAY_LEN(a) sizeof(a)/sizeof(a[0])
int main ()
{
    // 4 OMP threads, each does 2D FFT 50x100 points
    MKL_Complex8 x[4][50][100];
    int nth = ARRAY_LEN(x);
    MKL_LONG len[2] = {ARRAY_LEN(x[0]), ARRAY_LEN(x[0][0])};
    int th;
    // assume x is initialized and do 2D FFTs
#pragma omp parallel for shared(len, x)
    for (th = 0; th < nth; th++)
    {
        DFTI_DESCRIPTOR_HANDLE myFFT;

        DftiCreateDescriptor (&myFFT, DFTI_SINGLE, DFTI_COMPLEX, 2, len);
        DftiCommitDescriptor (myFFT);
        DftiComputeForward (myFFT, x[th]);
        DftiFreeDescriptor (&myFFT);
    }
    return 0;
}
```

Specify the number of OpenMP threads for [Example “Using Parallel Mode with Multiple Descriptors Initialized in One Thread”](#) like this:

set MKL_NUM_THREADS = 1 for Intel MKL to work in the single-threaded mode (obligatory);

set OMP_NUM_THREADS = 4 for the customer program to work in the multi-threaded mode.

Using Parallel Mode with Multiple Descriptors Initialized in One Thread

```
#include "mkl_dfti.h"
#include <omp.h>
#define ARRAY_LEN(a) sizeof(a)/sizeof(a[0])
int main ()
{
    // 4 OMP threads, each does 2D FFT 50x100 points
    MKL_Complex8 x[4][50][100];
    int nth = ARRAY_LEN(x);
    MKL_LONG len[2] = {ARRAY_LEN(x[0]), ARRAY_LEN(x[0][0])};
    DFTI_DESCRIPTOR_HANDLE FFT[ARRAY_LEN(x)];
```

```
int th;

for (th = 0; th < nth; th++)
    DftiCreateDescriptor (&FFT[th], DFTI_SINGLE, DFTI_COMPLEX, 2, len);
for (th = 0; th < nth; th++)
    DftiCommitDescriptor (FFT[th]);
// assume x is initialized and do 2D FFTs
#pragma omp parallel for shared(FFT, x)
for (th = 0; th < nth; th++)
    DftiComputeForward (FFT[th], x[th]);
for (th = 0; th < nth; th++)
    DftiFreeDescriptor (&FFT[th]);
return 0;
}
```

The following [Example “Using Parallel Mode with a Common Descriptor”](#) illustrates a parallel customer program with a common descriptor used in several threads.

Using Parallel Mode with a Common Descriptor

```
#include "mkl_dfti.h"
#include <omp.h>
#define ARRAY_LEN(a) sizeof(a)/sizeof(a[0])
int main ()
{
    // 4 OMP threads, each does 2D FFT 50x100 points
    MKL_Complex8 x[4][50][100];
    int nth = ARRAY_LEN(x);
    MKL_LONG len[2] = {ARRAY_LEN(x[0]), ARRAY_LEN(x[0][0])};
    DFTI_DESCRIPTOR_HANDLE FFT;
    int th;

    DftiCreateDescriptor (&FFT, DFTI_SINGLE, DFTI_COMPLEX, 2, len);
    DftiCommitDescriptor (FFT);
    // assume x is initialized and do 2D FFTs
#pragma omp parallel for shared(FFT, x)
    for (th = 0; th < nth; th++)
        DftiComputeForward (FFT, x[th]);
    DftiFreeDescriptor (&FFT);
    return 0;
}
```

Examples for Cluster FFT Functions

The following C example computes a 2-dimensional out-of-place FFT using the cluster FFT interface:

2D Out-of-place Cluster FFT Computation

```
DFTI_DESCRIPTOR_DM_HANDLE desc;
MKL_LONG len[2], v, i, j, n, s;
Complex *in, *out;

MPI_Init(...);

// Create descriptor for 2D FFT
len[0]=nx;
len[1]=ny;
DftiCreateDescriptorDM(MPI_COMM_WORLD, &desc, DFTI_DOUBLE, DFTI_COMPLEX, 2, len);
// Ask necessary length of in and out arrays and allocate memory
DftiGetValueDM(desc, CDFT_LOCAL_SIZE, &v);
in=(Complex*)malloc(v*sizeof(Complex));
```

```

out=(Complex*)malloc(v*sizeof(Complex));
// Fill local array with initial data. Current process performs n rows,
// 0 row of in corresponds to s row of virtual global array
DftiGetValueDM(desc,CDFT_LOCAL_NX,&n);
DftiGetValueDM(desc,CDFT_LOCAL_X_START,&s);
// Virtual global array globalIN is defined by function f as
// globalIN[i*ny+j]=f(i,j)
for(i=0;i<n;i++)
    for(j=0;j<ny;j++) in[i*ny+j]=f(i+s,j);
// Set that we want out-of-place transform (default is DFTI_INPLACE)
DftiSetValueDM(desc,DFTI_PLACEMENT,DFTI_NOT_INPLACE);
// Commit descriptor, calculate FFT, free descriptor
DftiCommitDescriptorDM(desc);
DftiComputeForwardDM(desc,in,out);
// Virtual global array globalOUT is defined by function g as
// globalOUT[i*ny+j]=g(i,j)
// Now out contains result of FFT. out[i*ny+j]=g(i+s,j)
DftiFreeDescriptorDM(&desc);
free(in);
free(out);
MPI_Finalize();

```

1D In-place Cluster FFT Computations

The C example below illustrates one-dimensional in-place cluster FFT computations effected with a user-defined workspace:

```

DFTI_DESCRIPTOR_DM_HANDLE desc;
MKL_LONG len,v,i,n_out,s_out;
Complex *in,*work;

MPI_Init(...);
// Create descriptor for 1D FFT
DftiCreateDescriptorDM(MPI_COMM_WORLD,&desc,DFTI_DOUBLE,DFTI_COMPLEX,1,len);
// Ask necessary length of array and workspace and allocate memory
DftiGetValueDM(desc,CDFT_LOCAL_SIZE,&v);
in=(Complex*)malloc(v*sizeof(Complex));
work=(Complex*)malloc(v*sizeof(Complex));
// Fill local array with initial data. Local array has n elements,
// 0 element of in corresponds to s element of virtual global array
DftiGetValueDM(desc,CDFT_LOCAL_NX,&n);
DftiGetValueDM(desc,CDFT_LOCAL_X_START,&s);
// Set work array as a workspace
DftiSetValueDM(desc,CDFT_WORKSPACE,work);
// Virtual global array globalIN is defined by function f as globalIN[i]=f(i)
for(i=0;i<n;i++) in[i]=f(i+s);
// Commit descriptor, calculate FFT, free descriptor
DftiCommitDescriptorDM(desc);
DftiComputeForwardDM(desc,in);
DftiGetValueDM(desc,CDFT_LOCAL_OUT_NX,&n_out);
DftiGetValueDM(desc,CDFT_LOCAL_OUT_X_START,&s_out);
// Virtual global array globalOUT is defined by function g as globalOUT[i]=g(i)
// Now in contains result of FFT. Local array has n_out elements,
// 0 element of in corresponds to s_out element of virtual global array.
// in[i]==g(i+s_out)
DftiFreeDescriptorDM(&desc);
free(in);
free(work);
MPI_Finalize();

```

Auxiliary Data Transformations

This section presents C examples for conversion from the Cartesian to polar representation of complex data and vice versa.

Conversion from Cartesian to polar representation of complex data

```
// Cartesian->polar conversion of complex data
// Cartesian representation:  $z = re + I*im$ 
// Polar representation:  $z = r * \exp(I*phi)$ 
#include <mkl_vml.h>

void
variant1_Cartesian2Polar(int n,const double *re,const double *im,
                        double *r,double *phi)
{
    vdHypot(n,re,im,r);          // compute radii r[]
    vdAtan2(n,im,re,phi);        // compute phases phi[]
}

void
variant2_Cartesian2Polar(int n,const MKL_Complex16 *z,double *r,double *phi,
                        double *temp_re,double *temp_im)
{
    vzAbs(n,z,r);                // compute radii r[]
    vdPackI(n, (double*)z + 0, 2, temp_re);
    vdPackI(n, (double*)z + 1, 2, temp_im);
    vdAtan2(n,temp_im,temp_re,phi); // compute phases phi[]
}
```

Conversion from polar to Cartesian representation of complex data

```
// Polar->Cartesian conversion of complex data.
// Polar representation:  $z = r * \exp(I*phi)$ 
// Cartesian representation:  $z = re + I*im$ 
#include <mkl_vml.h>

void
variant1_Polar2Cartesian(int n,const double *r,const double *phi,
                        double *re,double *im)
{
    vdSinCos(n,phi,im,re);        // compute direction, i.e.  $z[]/abs(z[])$ 
    vdMul(n,r,re,re);             // scale real part
    vdMul(n,r,im,im);            // scale imaginary part
}

void
variant2_Polar2Cartesian(int n,const double *r,const double *phi,
                        MKL_Complex16 *z,
                        double *temp_re,double *temp_im)
{
    vdSinCos(n,phi,temp_im,temp_re); // compute direction, i.e.  $z[]/abs(z[])$ 
    vdMul(n,r,temp_im,temp_im); // scale imaginary part
    vdMul(n,r,temp_re,temp_re); // scale real part
    vdUnpackI(n,temp_re,(double*)z + 0, 2); // fill in result.re
    vdUnpackI(n,temp_im,(double*)z + 1, 2); // fill in result.im
}
```

Bibliography

Glossary

A^H	Denotes the conjugate transpose of a general matrix A . <i>See also</i> conjugate matrix.
A^T	Denotes the transpose of a general matrix A . <i>See also</i> transpose.
band matrix	A general m -by- n matrix A such that $a_{ij} = 0$ for $ i - j > l$, where $1 < l < \min(m, n)$. For example, any tridiagonal matrix is a band matrix.
band storage	A special storage scheme for band matrices. A matrix is stored in a two-dimensional array: columns of the matrix are stored in the corresponding columns of the array, and <i>diagonals</i> of the matrix are stored in rows of the array.
BLAS	Abbreviation for Basic Linear Algebra Subprograms. These subprograms implement vector, matrix-vector, and matrix-matrix operations.
BRNG	Abbreviation for Basic Random Number Generator. Basic random number generators are pseudorandom number generators imitating i.i.d. random number sequences of uniform distribution. Distributions other than uniform are generated by applying different transformation techniques to the sequences of random numbers of uniform distribution.
BRNG registration	Standardized mechanism that allows a user to include a user-designed BRNG into the VSL and use it along with the predefined VSL basic generators.
Bunch-Kaufman factorization	Representation of a real symmetric or complex Hermitian matrix A in the form $A = PUDU^H P^T$ (or $A = PLDL^H P^T$) where P is a permutation matrix, U and L are upper and lower triangular matrices with unit diagonal, and D is a Hermitian block-diagonal matrix with 1-by-1 and 2-by-2 diagonal blocks. U and L have 2-by-2 unit diagonal blocks corresponding to the 2-by-2 blocks of D .
c	When found as the first letter of routine names, <i>c</i> indicates the usage of single-precision complex data type.
CBLAS	C interface to the BLAS. <i>See</i> BLAS.
CDF	Cumulative Distribution Function. The function that determines probability distribution for univariate or multivariate random variable X . For univariate distribution the cumulative distribution function is the function of real argument x , which for every x takes a value equal to probability of the event $A: X \leq x$. For multivariate distribution the cumulative distribution function is the function of a real vector $x = (x_1, x_2, \dots, x_n)$, which, for every x , takes a value equal to probability of the event $A = (X_1 \leq x_1 \ \& \ X_2 \leq x_2, \ \& \ \dots, \ \& \ X_n \leq x_n)$.

Cholesky factorization	Representation of a symmetric positive-definite or, for complex data, Hermitian positive-definite matrix A in the form $A = U^H U$ or $A = L L^H$, where L is a lower triangular matrix and U is an upper triangular matrix.
condition number	The number $\kappa(A)$ defined for a given square matrix A as follows: $\kappa(A) = \ A\ \ A^{-1}\ $.
conjugate matrix	The matrix A^H defined for a given general matrix A as follows: $(A^H)_{ij} = (a_{ji})^*$.
conjugate number	The conjugate of a complex number $z = a + bi$ is $z^* = a - bi$.
d	When found as the first letter of routine names, d indicates the usage of double-precision real data type.
dot product	The number denoted $x \cdot y$ and defined for given vectors x and y as follows: $x \cdot y = \sum_i x_i y_i$. Here x_i and y_i stand for the i -th elements of x and y , respectively.
double precision	A floating-point data type. On Intel® processors, this data type allows you to store real numbers x such that $2.23 \times 10^{-308} < x < 1.79 \times 10^{308}$. For this data type, the machine precision ϵ is approximately 10^{-15} , which means that double-precision numbers usually contain no more than 15 significant decimal digits. For more information, refer to <i>Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1: Basic Architecture</i> .
eigenvalue	See eigenvalue problem.
eigenvalue problem	A problem of finding non-zero vectors x and numbers λ (for a given square matrix A) such that $Ax = \lambda x$. Here the numbers λ are called the eigenvalues of the matrix A and the vectors x are called the eigenvectors of the matrix A .
eigenvector	See eigenvalue problem.
elementary reflector(Householder matrix)	Matrix of a general form $H = I - \tau v v^T$, where v is a column vector and τ is a scalar. In LAPACK elementary reflectors are used, for example, to represent the matrix Q in the QR factorization (the matrix Q is represented as a product of elementary reflectors).
factorization	Representation of a matrix as a product of matrices. See also Bunch-Kaufman factorization, Cholesky factorization, LU factorization, LQ factorization, QR factorization, Schur factorization.
FFTs	Abbreviation for Fast Fourier Transforms. See Chapter 11 of this book.
full storage	A storage scheme allowing you to store matrices of any kind. A matrix A is stored in a two-dimensional array a , with the matrix element a_{ij} stored in the array element $a(i, j)$.
Hermitian matrix	A square matrix A that is equal to its conjugate matrix A^H . The conjugate A^H is defined as follows: $(A^H)_{ij} = (a_{ji})^*$.
I	See identity matrix.
identity matrix	A square matrix I whose diagonal elements are 1, and off-diagonal elements are 0. For any matrix A , $AI = A$ and $IA = A$.

i.i.d.	Independent Identically Distributed.
in-place	Qualifier of an operation. A function that performs its operation in-place takes its input from an array and returns its output to the same array.
Intel MKL	Abbreviation for Intel® Math Kernel Library.
inverse matrix	The matrix denoted as A^{-1} and defined for a given square matrix A as follows: $AA^{-1} = A^{-1}A = I$. A^{-1} does not exist for singular matrices A .
LQ factorization	Representation of an m -by- n matrix A as $A = LQ$ or $A = \begin{pmatrix} L & 0 \end{pmatrix} Q$. Here Q is an n -by- n orthogonal (unitary) matrix. For $m \leq n$, L is an m -by- m lower triangular matrix with real diagonal elements; for $m > n$, where L_1 is an n -by- n lower triangular matrix, and L_2 is a rectangular matrix.
LU factorization	Representation of a general m -by- n matrix A as $A = PLU$, where P is a permutation matrix, L is lower triangular with unit diagonal elements (lower trapezoidal if $m > n$) and U is upper triangular (upper trapezoidal if $m < n$).
machine precision	The number ε determining the precision of the machine representation of real numbers. For Intel® architecture, the machine precision is approximately 10^{-7} for single-precision data, and approximately 10^{-15} for double-precision data. The precision also determines the number of significant decimal digits in the machine representation of real numbers. See also double precision and single precision.
MPI	Message Passing Interface. This standard defines the user interface and functionality for a wide range of message-passing capabilities in parallel computing.
MPICH	A freely available, portable implementation of MPI standard for message-passing libraries.
orthogonal matrix	A real square matrix A whose transpose and inverse are equal, that is, $A^T = A^{-1}$, and therefore $AA^T = A^TA = I$. All eigenvalues of an orthogonal matrix have the absolute value 1.
packed storage	A storage scheme allowing you to store symmetric, Hermitian, or triangular matrices more compactly. The upper or lower triangle of a matrix is packed by columns in a one-dimensional array.
PDF	Probability Density Function. The function that determines probability distribution for univariate or multivariate continuous random variable X . The probability density function $f(x)$ is closely related with the cumulative distribution function $F(x)$. For univariate distribution the relation is

$$F(x) = \int_{-\infty}^x f(t)dt .$$

For multivariate distribution the relation is

$$F(x_1, x_2, \dots, x_n) = \int_{-\infty}^{x_1} \int_{-\infty}^{x_2} \dots \int_{-\infty}^{x_n} f(t_1, t_2, \dots, t_n) dt_1 dt_2 \dots dt_n$$

positive-definite matrix	A square matrix A such that $Ax \cdot x > 0$ for any non-zero vector x . Here $\cdot$ denotes the dot product.
pseudorandom number generator	A completely deterministic algorithm that imitates truly random sequences.
QR factorization	Representation of an m -by- n matrix A as $A = QR$, where Q is an m -by- m orthogonal (unitary) matrix, and R is n -by- n upper triangular with real diagonal elements (if $m \geq n$) or trapezoidal (if $m < n$) matrix.
random stream	An abstract source of independent identically distributed random numbers of uniform distribution. In this manual a random stream points to a structure that uniquely defines a random number sequence generated by a basic generator associated with a given random stream.
RNG	Abbreviation for Random Number Generator. In this manual the term "random number generators" stands for pseudorandom number generators, that is, generators based on completely deterministic algorithms imitating truly random sequences.
Rectangular Full Packed (RFP) storage	A storage scheme combining the full and packed storage schemes for the upper or lower triangle of the matrix. This combination enables using half of the full storage as packed storage while maintaining efficiency by using Level 3 BLAS/LAPACK kernels as the full storage.
s	When found as the first letter of routine names, s indicates the usage of single-precision real data type.
ScaLAPACK	Stands for Scalable Linear Algebra PACKage.
Schur factorization	Representation of a square matrix A in the form $A = ZTZ^H$. Here T is an upper quasi-triangular matrix (for complex A , triangular matrix) called the Schur form of A ; the matrix Z is orthogonal (for complex A , unitary). Columns of Z are called Schur vectors.
single precision	A floating-point data type. On Intel® processors, this data type allows you to store real numbers x such that $1.18 \times 10^{-38} < x < 3.40 \times 10^{38}$. For this data type, the machine precision (ϵ) is approximately 10^{-7} , which means that single-precision numbers usually contain no more than 7 significant decimal digits. For more information, refer to <i>Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 1: Basic Architecture</i> .
singular matrix	A matrix whose determinant is zero. If A is a singular matrix, the inverse A^{-1} does not exist, and the system of equations $Ax = b$ does not have a unique solution (that is, there exist no solutions or an infinite number of solutions).
singular value	The numbers defined for a given general matrix A as the eigenvalues of the matrix AA^H . See also SVD.

SMP	Abbreviation for Symmetric MultiProcessing. The MKL offers performance gains through parallelism provided by the SMP feature.
sparse BLAS	Routines performing basic vector operations on sparse vectors. Sparse BLAS routines take advantage of vectors' sparsity: they allow you to store only non-zero elements of vectors. See BLAS.
sparse vectors	Vectors in which most of the components are zeros.
storage scheme	The way of storing matrices. See full storage, packed storage, and band storage.
SVD	Abbreviation for Singular Value Decomposition. See <i>also</i> Singular value decomposition section in Chapter 5.
symmetric matrix	A square matrix A such that $a_{ij} = a_{ji}$.
transpose	The transpose of a given matrix A is a matrix A^T such that $(A^T)_{ij} = a_{ji}$ (rows of A become columns of A^T , and columns of A become rows of A^T).
trapezoidal matrix	A matrix A such that $A = (A_1 A_2)$, where A_1 is an upper triangular matrix, A_2 is a rectangular matrix.
triangular matrix	A matrix A is called an upper (lower) triangular matrix if all its subdiagonal elements (superdiagonal elements) are zeros. Thus, for an upper triangular matrix $a_{ij} = 0$ when $i > j$; for a lower triangular matrix $a_{ij} = 0$ when $i < j$.
tridiagonal matrix	A matrix whose non-zero elements are in three diagonals only: the leading diagonal, the first subdiagonal, and the first super-diagonal.
unitary matrix	A complex square matrix A whose conjugate and inverse are equal, that is, that is, $A^H = A^{-1}$, and therefore $AA^H = A^H A = I$. All eigenvalues of a unitary matrix have the absolute value 1.
VML	Abbreviation for Vector Mathematical Library. See Chapter 9 of this book.
VSL	Abbreviation for Vector Statistical Library. See Chapter 10 of this book.
z	When found as the first letter of routine names, z indicates the usage of double-precision complex data type.
