Notices & Disclaimers

This document contains information on products in the design phase of development. The information here is subject to change without notice. Do not finalize a design with this information.

Intel technologies may require enabled hardware, software or service activation.

No product or component can be absolutely secure.

Your costs and results may vary.

You may not use or facilitate the use of this document in connection with any infringement or other legal analysis concerning Intel products described herein. You agree to grant Intel a non-exclusive, royalty-free license to any patent claim thereafter drafted which includes subject matter disclosed herein.

All product plans and roadmaps are subject to change without notice.

The products described may contain design defects or errors known as errata which may cause the product to deviate from published specifications. Current characterized errata are available on request.

Intel disclaims all express and implied warranties, including without limitation, the implied warranties of merchantability, fitness for a particular purpose, and non-infringement, as well as any warranty arising from course of performance, course of dealing, or usage in trade.

Code names are used by Intel to identify products, technologies, or services that are in development and not publicly available. These are not “commercial” names and not intended to function as trademarks.

No license (express or implied, by estoppel or otherwise) to any intellectual property rights is granted by this document, with the sole exception that a) you may publish an unmodified copy and b) code included in this document is licensed subject to the Zero-Clause BSD open source license (0BSD), https://opensource.org/licenses/0BSD. You may create software implementations based on this document and in compliance with the foregoing that are intended to execute on the Intel product(s) referenced in this document. No rights are granted to create modifications or derivatives of this document.

| -025     | - Removed instructions that now reside in the Intel® 64 and IA-32 Architectures Software Developer’s Manual.  
- Minor updates to chapter 1.  
- Updates to Table 2-1, Table 2-2 and Table 2-8 (leaf 07H) to indicate support for AVX512_4VNNIW and AVX512_4FMAPS.  
- Minor update to Table 2-8 (leaf 15H) regarding ECX definition.  
- Minor updates to Section 4.6.2 and Section 4.6.3 to clarify the effects of “suppress all exceptions”.  
- Footnote addition to CLWB instruction indicating operand encoding requirement.  
- Removed PCOMMIT. | September 2016 |
| -026     | - Removed CLWB instruction; it now resides in the Intel® 64 and IA-32 Architectures Software Developer’s Manual.  
- Added additional 512-bit instruction extensions in chapter 6. | October 2016 |
| -027     | - Added TLB CPUID leaf in chapter 2.  
- Added VPOPCNTD/Q instruction in chapter 6, and CPUID details in chapter 2. | December 2016 |
| -029     | - Corrected typo in CPUID leaf 18H.  
- Updated operand encoding table format; extracted tuple information from operand encoding.  
- Added VPERMB back into chapter 5; inadvertently removed.  
- Moved all instructions from chapter 6 to chapter 5.  
- Updated operation section of VPMULTISHIFTQB. | April 2017 |
| -030     | - Removed unnecessary information from document (chapters 2, 3 and 4).  
- Added table listing recent instruction set extensions introduction in Intel 64 and IA-32 Processors.  
- Updated CPUID instruction with additional details.  
- Added the following instructions: GF2P8AFFINEINVQB, GF2P8AFFINEQQB, GF2P8MULB, VAESDEC, VAESDECLAST, VAESENC, VAESENCLAST, VPCMULQDQ, VPCOMPRESS, VPDPBUSD, VPDPBUSDS, VPDPWSSD, VPDPWSSSDS, VPEXPAND, VPOPCNT, VPSHLD, VPSHLDV, VPSHRD, VPSHRDV, VPSHUFBITQMB.  
- Removed the following instructions: VPMADD52HUQ, VPMADD52LUQ, VPERMB, VPERM12B, VPERMT2B, and VPMULTISHIFTQB. They can be found in the Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volumes 2A, 2B, 2C, & 2D.  
- Moved instructions unique to processors based on the Knights Mill microarchitecture to chapter 3.  
- Added chapter 4: EPT-Based Sub-Page Permissions.  
- Added chapter 5: Intel® Processor Trace: VMX Improvements. | October 2017 |
<table>
<thead>
<tr>
<th>Revision</th>
<th>Description</th>

</thead>
</table>
| -031     | • Updated change log to correct typo in changes from previous release.  
• Updated instructions with imm8 operand missing in operand encoding table.  
• Replaced “VLMAX” with “MAXVL” to align terminology used across documentation.  
• Added back information on detection of Intel AVX-512 instructions.  
• Added Intel® Memory Encryption Technologies instructions PCONFIG and WBNOINVD. These instructions are also added to Table 1-1 “Recent Instruction Set Extensions Introduction in Intel 64 and IA-32 Processors”. Added Section 1.5 “Detection of Intel® Memory Encryption Technologies (Intel® MKTME) Instructions”.  
• CPUID instruction updated with PCONFIG and WBNOINVD details.  
• CPUID instruction updated with additional details on leaf 07H: Intel® Xeon Phi™ only features identified and listed.  
• CPUID instruction updated with new Intel® SGX features in leaf 12H.  
• CPUID instruction updated with new PCONFIG information sub-leaf 1BH.  
• Updated short descriptions in the following instructions: VPDPBUSD, VPDPBUSDS, VPDPWSSD and VPDPWSSDS.  
• Corrections and clarifications in Chapter 4 “EPT-Based Sub-Page Permissions”.  
• Corrections and clarifications in Chapter 5 “Intel® Processor Trace: VMX Improvements”.  
| January 2018 |
| -032     | • Corrected PCONFIG CPUID feature flag on instruction page.  
• Minor updates to PCONFIG instruction pages: Changed Table 2-2 to use Hex notation; changed “RSVD, MBZ” to “Reserved, must be zero” in two places in Table 2-3.  
• Minor typo correction in WBNOINVD instruction description.  
| January 2018 |
| -033     | • Updated Table 1-2 "Recent Instruction Set Extensions / Features Introduction in Intel® 64 and IA-32 Processors".  
• Added Section 1.4, “Detection of Future Instructions and Features”.  
• Added CLDEMOTE, MOVDIRI, MOVDIR64B, TPAUSE, UMONITOR and UMWAIT instructions.  
• Updated the CPUID instruction with details on new instructions/features added, as well as new power management details and information on hardware feedback interface ISA extensions.  
• Corrections to PCONFIG instruction.  
• Moved instructions unique to processors based on the Knights Mill microarchitecture to the Intel® 64 and IA-32 Architectures Software Developer’s Manual.  
• Added Chapter 5 “Hardware Feedback Interface ISA Extensions”.  
• Added Chapter 6 “AC Split Lock Detection”.  
| March 2018 |
| -034     | • Added clarification to leaf 07H in the CPUID instruction.  
• Added MSR index for IA32_UMWAIT_CONTROL MSR.  
• Updated registers in TPAUSE and UMWAIT instructions.  
• Updated TPAUSE and UMWAIT intrinsics.  
<p>| May 2018 |</p>
<table>
<thead>
<tr>
<th>Revision</th>
<th>Description</th>

</thead>
</table>
| -035     | • Updated Table 1-2 "Recent Instruction Set Extensions / Features Introduction in Intel® 64 and IA-32 Processors" to list the AVX512_VNNI instruction set architecture on a separate line due to presence on future processors available sooner than previously listed.  
• Updated CPUID instruction in various places.  
• Removal of NDD/DDS/NDS terms from instructions. Note: Previously, the terms NDS, NDD and DDS were used in instructions with an EVEX (or VEX) prefix. These terms indicated that the vvvv field was valid for encoding, and specified register usage. These terms are no longer necessary and are redundant with the instruction operand encoding tables provided with each instruction. The instruction operand encoding tables give explicit details on all operands, indicating where every operand is stored and if they are read or written. If vvvv is not listed as an operand in the instruction operand encoding table, then EVEX (or VEX) vvvv must be 0b1111.  
• Added additional #GP exception condition to TPAUSE and UMWAIT.  
• Updated Chapter 5 "Hardware Feedback Interface ISA Extensions" as follows: changed scheduler/software to operating system or OS, changed LP0 Scheduler Feedback to LP0 Capability Values, various description updates, clarified that capability updates are independent, and added an update to clarify that bits 0 and 1 will always be set together in Section 5.1.4.  
• Added IA32_CORE_CAPABILITY MSR to Chapter 6 "AC Split Lock Detection". | October 2018 |
| -036     | • Added AVX512_BF16 instructions in chapter 2; related CPUID information updated in chapter 1.  
• Added new section to chapter 1 describing bfloat16 format.  
• CPUID leaf updates to align with the Intel® 64 and IA-32 Architectures Software Developer’s Manual.  
• Removed CLDEMOTE, TPAUSE, UMONITOR, and UMWAIT instructions; they now reside in the Intel® 64 and IA-32 Architectures Software Developer’s Manual.  
• Changes now marked by green change bars and green font in order to view changes at a text level. | April 2019 |
| -037     | • Removed chapter 3, "EPT-Based Sub-Page Permissions"; chapter 4, "Intel® Processor Trace: VMX Improvements"; and chapter 6, "Split Lock Detection"; this information is in the Intel® 64 and IA-32 Architectures Software Developer’s Manual.  
• Removed MOVDIRI and MOVDIR64B instructions; they now reside in the Intel® 64 and IA-32 Architectures Software Developer’s Manual.  
• Updated Table 1-2 with new features in future processors.  
• Updated Table 1-3 with support for AVX512_VP2INTERSECT.  
• Updated Table 1-5 with support for ENQCMD: Enqueue Stores.  
• Added ENQCMD/ENQCMDMS and VP2INTERSECTD/VP2INTERSECTQ instructions, and updated CPUID accordingly.  
• Added new chapter: Chapter 4, UC-Lock Disable. | May 2019 |
<table>

</table>
| -038     | - Removed instruction extensions/features from Table 1-2 "Recent Instruction Set Extensions / Features Introduction in Intel® 64 and IA-32 Processors" that are available in processors covered in the Intel® 64 and IA-32 Architectures Software Developer’s Manual. This information can be found in Chapter 5 "Instruction Set Summary", of Volume 1.  
- In Section 1.7, "Detection of Future Instructions", removed instructions from Table 1-5 "Future Instructions" that are available in processors covered in the Intel® 64 and IA-32 Architectures Software Developer’s Manual.  
- Removed instructions with the following CPUID feature flags: AVX512_VNNI, VAES, GFNI (AVX/AVX512), AVX512_VBMI2, VPCLMULQDQ, AVX512_BITALG; they now reside in the Intel® 64 and IA-32 Architectures Software Developer’s Manual.  
- CPUID instruction updated with Hybrid information sub-leaf 1AH, SERIALIZE and TSXLDTRK support, updates to the L3 Cache Intel RDT Monitoring Capability Enumeration Sub-leaf, and updates to the Memory Bandwidth Allocation Enumeration Sub-leaf.  
- Replaced ← with := notation in operation sections of instructions. These changes are not marked with change bars.  
- Added the following instructions: SERIALIZE, XRESLDTRK, XSUSLDTRK.  
- Update to the VDPBF16PS instruction.  
- Updates to Chapter 4, "Hardware Feedback Interface ISA Extensions".  
- Added Chapter 5, "TSX Suspend Load Address Tracking".  
- Added Chapter 6, "Hypervisor-managed Linear Address Translation".  
- Added Chapter 7, "Architectural Last Branch Records (LBRs)".  
- Added Chapter 8, "Non-Write-Back Lock Disable Architecture".  
- Added Chapter 9, "Intel® Resource Director Technology Feature Updates". | March 2020 |
| -039     | - Updated Section 1.1 "About this Document" to reflect chapter changes in this release.  
- Added Section 1.2 "DisplayFamily and DisplayModel for Future Processors".  
- Updated Table 1-2 "Recent Instruction Set Extensions / Features Introduction in Intel® 64 and IA-32 Processors".  
- CPUID instruction updated.  
- Removed Chapter 4 "Hardware Feedback Interface". This information is now in the Intel® 64 and IA-32 Architectures Software Developer’s Manual.  
- Updated Figure 5-1 "Example HLAT Software Usage".  
- Added Table 6-5 "Encodings for 64-Bit Guest-State Fields (0010_10xx xxxx xxxxAb)" to Chapter 6.  
- Added Chapter 8 "Bus Lock and VM Notify". | June 2020 |
| -040     | - Updated Section 1.1 "About this Document" to reflect chapter changes in this release.  
- Updated Table 1-2 "Recent Instruction Set Extensions / Features Introduction in Intel® 64 and IA-32 Processors".  
- CPUID instruction updated.  
- Added notation updates to the beginning of Chapter 2. Updated ENQCMD and ENQCMDS instructions to use this notation.  
- Added Chapter 3, "Intel® AMX Instruction Set Reference, A-Z".  
- Minor updates to Chapter 6, "Hypervisor-managed Linear Address Translation". | June 2020 |

</table>
| -041     | - Updated Section 1.1 "About this Document” to reflect chapter changes in this release.  
- Updated Table 1-2 "Recent Instruction Set Extensions / Features Introduction in Intel® 64 and IA-32 Processors".  
- CPUID instruction updated for enumeration of several new features.  
- PCONFIG instruction updated.  
- Added CLUI, HRESET, SENDUIPI, STUI, TEXIT, UIRET, VPDPBUSD, VPDPBUSDS, VPDPWSSD, and VPDPWSSDS instructions to Chapter 2.  
- Updated Figure 3-2, "The TMUL Unit".  
- Update to pseudocode of TILELOADD/TILELOADDT1 instruction.  
- Addition to Section 6.2, "VMCS Changes".  
- Update to Section 7.1.2.4, "Call-Stack Mode".  
- Update to Section 9.1 "Bus Lock Debug Exception".  
- Added Chapter 11, "User Interrupts".  
- Added Chapter 12, "Performance Monitoring Updates".  
- Added Chapter 13, "Enhanced Hardware Feedback Interface". | October 2020 |
| -042     | - CPUID instruction updated.  
- Removed the following instructions: VCVTNE2PS2BF16, VCVTNEPS2BF16, VDPBF16PS, VP2INTERSECTD/VP2INTERSECTQ, and WBN0INV. They can be found in the Intel® 64 and IA-32 Architectures Software Developer's Manual, Volume 2C.  
- Updated bit positions in Section 6.12, "Changes to VMX Capability Reporting".  
- Typo correction in Chapter 8, "Non-Write-Back Lock Disable Architecture".  
- Several updates to Chapter 13, "Enhanced Hardware Feedback Interface (EHFI)".  
- Added Chapter 14, "Linear Address Masking (LAM)".  
- Added Chapter 15, "Error Codes for Processors Based on Sapphire Rapids Microarchitecture". | December 2020 |
| -043     | - Updated CPUID instruction.  
- Typo correction in Table 8-2, “TEST_CTRL MSR”.  
- Typo corrections in Section 14.1, "Enumeration, Enabling, and Configuration". | February 2021 |
| -044     | - Updated Table 1-2, "Recent Instruction Set Extensions / Features Introduction in Intel® 64 and IA-32 Processors".  
- Updated CPUID instruction.  
- Updates to the ENQCMD and ENQCMDS instructions.  
- Removed the PCONFIG instruction; it can be found in the Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 2B.  
- Corrected typo in the VPDPBUSD instruction.  
- Updates to Table 3-1, "Intel® AMX Exception Classes".  
- Change in terminology updates in Chapter 7, "Architectural Last Branch Records (LBRs)".  
- Updated Chapter 6 to introduce the official technology name: Intel® Virtualization Technology - Redirect Protection.  
- Added Chapter 16, "IPI Virtualization". | May 2021 |

| -045     | • Chapter 1: Updated the CPUID instruction.  
          • Chapter 2: Updated ENQCMD and ENQCMDS to remove statements that these instructions ignore unused bits; this is incorrect. Removed HRESET, SERIALIZE, VPDPBUSD, VPDPBUSDS, VPDPWSSD, and VPDPWSSDS instructions; these instructions can be found in the Intel 64 and IA-32 Architectures Software Developer’s Manual. Updates to SENDUIPI instruction operand encoding and 64-bit mode exceptions. Update to UIRET pseudocode.  
          • Chapter 3: Updated Section 3.3., “Recommendations for System Software”.  
          • Removed Chapter 6, “Intel® Virtualization Technology: Redirect Protection”; this information can be found in the Intel 64 and IA-32 Architectures Software Developer’s Manual.  
          • Removed Chapter 7, “Architectural Last Branch Records (LBRs)”; this information can be found in the Intel 64 and IA-32 Architectures Software Developer’s Manual.  
          • Removed Chapter 12, “Performance Monitoring Updates”; this information can be found in the Intel 64 and IA-32 Architectures Software Developer’s Manual.  
          • Removed Chapter 13, “Enhanced Hardware Feedback Interface (EHFI)”; this information can be found in the Intel 64 and IA-32 Architectures Software Developer’s Manual.  
          • Updated Section 7.1.1, “Bus Lock VM Exit” to provide additional clarity and details.  
          • Updated Chapter 8, “Intel® Resource Director Technology Feature Updates” to update MBA 3.0 information.  
          • Update to Section 9.5.1, “User-Interrupt Notification Identification”.  
          • Minor updates to Chapter 10, “Linear Address Masking (LAM)”, to provide additional clarity.  
          • Corrected two typos in the current Table 11-1, “Intel IMC MC Error Codes for IA32_MCI_STATUS (i= 13-20).”  
          • Added Chapter 13, “Asynchronous Enclave Exit Notify and the EDECCSSA User Leaf Function.” | June 2022 |
| -046     | • Chapter 1: Updated Table 1-1, “CPUID Signature Values of DisplayFamily_DisplayModel.” Updated Table 1-2, “Recent Instruction Set Extensions / Features Introduction in Intel® 64 and IA-32 Processors.” Updated the CPUID instruction.  
          • Chapter 2: Added the following instructions: AADD, AAND, AOR, AXOR, CMPccXADD, RDMRSRLIST, VBCTNEBF162PS, VBCTNESH2PS, VCVTNEBF162PS, VCVTNEEPH2PS, VCVTNEOBF162PS, VCVTNEOPH2PS, VCVTNEPS2BF16, VPDPB[SU,UU,SS][,S], VPMADD52HUQ, VPMADD52LUQ, WRMSRLIST, and WRMSRNS.  
          • Chapter 3: Added section 3.4, “Operand Restrictions,” and added the TDPFP16PS instruction.  
          • Added Chapter 14, “Code Prefetch Instruction Updates.”  
          • Added Chapter 15, “Next Generation Performance Monitoring Unit (PMU).” | September 2022 |
<table>
<thead>
<tr>
<th>Revision</th>
<th>Description</th>

</thead>
</table>
| -047     | • Chapter 1: Updated Table 1-1, "CPUID Signature Values of DisplayFamily_DisplayModel." Updated Table 1-2, "Recent Instruction Set Extensions / Features Introduction in Intel® 64 and IA-32 Processors." Updated the CPUID instruction.  
  • Chapter 3: Notes added and naming updates as necessary.  
  • Removed the following chapters: Chapter 4, "Enqueue Stores and Process Address Space Identifiers (PASIDs)," Chapter 5, "Intel® TSX Suspend Load Address Tracking," Chapter 9, "User Interrupts," Chapter 11, "Error Codes for Processors Based on Sapphire Rapids Microarchitecture," and Chapter 12, "IPI Virtualization." This information can be found in the Intel 64 and IA-32 Architectures Software Developer's Manuals.  
  • Removed the following instructions: CLUI, ENQCMD, ENQCMDS, LDTILECFG, SENDUIPI, SstileCFG, STUI, TDPBF16PS, TDPBSSD/TDPBUSD/TDPBUSD/TDPBUUD, TESTUI, TILELOAD/TILELOADDT1, TILERELEASE, TILESTORED, TILEZERO, UIRET, XRESLDTTRK, and XSUSLDTTRK. These instructions can be found in the Intel 64 and IA-32 Architectures Software Developer's Manuals.  
  • Chapter 4: Updates to MSR name and description of bits.  
  • Chapter 6: Updates to information, including naming changes and typo corrections as necessary.  
  • Chapter 10: Update to the description of the Retire Latency field given in Section 10.3.1, "Timed Processor Event Based Sampling."  
  • Added Chapter 11, "Linear Address Space Separation (LASS)."  
  • Added Chapter 12, "Virtualization of the IA32_SPEC_CTRL MSR."  
  • Added Chapter 13, "Remote Atomic Operations in Intel Architecture." | December 2022 |
| -048     | • Chapter 1: Updated Table 1-2, "Recent Instruction Set Extensions / Features Introduction in Intel® 64 and IA-32 Processors." Updated the CPUID instruction.  
  • Chapter 3: Added the TCMIMFP16PS/TCMRLFP16PS instructions.  
  • Chapter 4: The majority of the chapter was updated to describe the UC-lock disable feature.  
  • Chapter 8: Significant updates throughout the chapter. Added new Section 8.3.2, "Counters Snapshotting," new Section 8.4, "LBR Enhancements," and new Section 8.5, "PerfMon MSRs Aliasing."  
  • Removal of chapters: Removed previous Chapter 4, "Non-Write-Back Lock Disable Architecture." Removed previous Chapter 5, "Bus Lock and VM Notify." Removed previous Chapter 8, "Asynchronous Enclave Exit Notify and the EDECSSA User Leaf Function." The information from these chapters can be found in the Intel 64 and IA-32 Architectures Software Developer’s Manuals. | March 2023 |
<table>
<thead>
<tr>
<th>Revision</th>

</thead>
</table>
| -049     | • Chapter 1: Updated Table 1-1, “Signature Values of DisplayFamily_DisplayModel.” Updated Table 1-2, “Recent Instruction Set Extensions / Features Introduction in Intel® 64 and IA-32 Processors.” Updated the CPUID instruction with bits enumerating new features. Updated the CPUID instruction to add the initial EAX value to each main CPUID leaf name in order to accommodate new bookmarks in the final PDF that will enable readers to jump to any main CPUID leaf of interest. Where there are multiple initial EAX values, those values have been tagged so they will show up underneath the main CPUID leaf name in the final PDF.  
• Chapter 2: Added the PBNDKB, updated PCONFIG, VPDPW[S,US,UU]D[,S], VSHA512MSG1, VSHA512MSG2, VSHA512RNDSD2, VSM3MSG1, VSM3MSG2, VSM3RNDSD2, VSM4KEY4, and VSM4RNDSD4 instructions.  
• Chapter 8: Added notes regarding the availability of the IA32_PERF_CAPABILITIES.PEBS_FMT of 6.  
• Removed previous Chapter 10, “Virtualization of the IA32_SPEC_CTRL MSR.” This information can be found in the Intel 64 and IA-32 Architectures Software Developer’s Manuals.  
• Added new Chapter 11, “Total Storage Encryption in Intel Architecture.”  
• Updated text changes and change bars from using the color green to use the color violet for better accessibility for all readers. | June 2023 |
8.1.1 CPUID Sub-Leafing ................................................................. 8-1
8.1.2 Reporting Per Logical Processor ........................................ 8-2
8.1.3 General-Purpose Counters Bitmap ...................................... 8-2
8.1.4 Fixed-Function Counters True-View Bitmap ......................... 8-2
8.1.5 Architectural Performance Monitoring Events Bitmap .......... 8-2
8.1.6 Non-Architectural Performance Capabilities .................... 8-2

1.1 ABOUT THIS DOCUMENT

This document describes the software programming interfaces of Intel® architecture instruction extensions and features which may be included in future Intel processor generations. Intel does not guarantee the availability of these interfaces and features in any future product.

The instruction set extensions cover a diverse range of application domains and programming usages. The 512-bit SIMD vector SIMD extensions, referred to as Intel® Advanced Vector Extensions 512 (Intel® AVX-512) instructions, deliver comprehensive set of functionality and higher performance than Intel® Advanced Vector Extensions (Intel® AVX) and Intel® Advanced Vector Extensions 2 (Intel® AVX2) instructions. Intel AVX, Intel AVX2 and many Intel AVX-512 instructions are covered in the Intel® 64 and IA-32 Architectures Software Developer’s Manual. The reader can refer to them for basic and more background information related to various features referenced in this document.

The base of the 512-bit SIMD instruction extensions are referred to as Intel AVX-512 Foundation instructions. They include extensions of the Intel AVX and Intel AVX2 family of SIMD instructions but are encoded using a new encoding scheme with support for 512-bit vector registers, up to 32 vector registers in 64-bit mode, and conditional processing using opmask registers.

Chapter 2 is an instruction set reference, providing details on new instructions.

Chapter 3 describes the Intel® Advanced Matrix Extensions (Intel® AMX).

Chapter 4 describes the UC-lock disable feature.

Chapter 5 describes Intel® Resource Director Technology feature updates.

Chapter 6 describes Linear Address Masking (LAM).

Chapter 7 describes updates to the code prefetch instructions available in future processors.

Chapter 8 describes the next generation Performance Monitoring Unit enhancements available in future processors.

Chapter 9 describes Linear Address Space Separation (LASS).

Chapter 10 describes Remote Atomic Operations (RAO) in Intel architecture.

Chapter 11 describes Total Storage Encryption (TSE) in Intel architecture.

1.2 DISPLAYFAMILY AND DISPLAYMODEL FOR FUTURE PROCESSORS

Table 1-1 lists the signature values of DisplayFamily and DisplayModel for future processor families discussed in this document.

1.4 DETECTION OF FUTURE INSTRUCTIONS AND FEATURES

Future instructions and features are enumerated by a CPUID feature flag; details can be found in Table 1-3.

1.5 CPUID INSTRUCTION
CPUID—CPU Identification

<table>
<thead>
<tr>
<th>Opcode</th>
<th>Instruction</th>
<th>64-Bit Mode</th>
<th>Compat/ Leg Mode</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>0F A2</td>
<td>CPUID</td>
<td>Valid</td>
<td>Valid</td>
<td>Returns processor identification and feature information to the EAX, EBX, ECX, and EDX registers, as determined by input entered in EAX (in some cases, ECX as well).</td>
</tr>
</tbody>
</table>

**Description**

The ID flag (bit 21) in the EFLAGS register indicates support for the CPUID instruction. If a software procedure can set and clear this flag, the processor executing the procedure supports the CPUID instruction. This instruction operates the same in non-64-bit modes and 64-bit mode.

CPUID returns processor identification and feature information in the EAX, EBX, ECX, and EDX registers. The instruction’s output is dependent on the contents of the EAX register upon execution (in some cases, ECX as well). For example, the following pseudocode loads EAX with 00H and causes CPUID to return a Maximum Return Value and the Vendor Identification String in the appropriate registers:

```
MOV EAX, 00H
CPUID
```

Table 1-3 shows information returned, depending on the initial value loaded into the EAX register.

Two types of information are returned: basic and extended function information. If a value is entered for CPUID.EAX is invalid for a particular processor, the data for the highest basic information leaf is returned. For example, using the Intel Core 2 Duo E6850 processor, the following is true:

```
CPUID.EAX = 05H (* Returns MONITOR/MWAIT leaf. *)
CPUID.EAX = 0AH (* Returns Architectural Performance Monitoring leaf. *)
CPUID.EAX = 0BH (* INVALID: Returns the same information as CPUID.EAX = 0AH. *)
CPUID.EAX = 1FH (* Returns V2 Extended Topology Enumeration leaf. *)
CPUID.EAX = 8000000BH (* Returns virtual/physical address size data. *)
CPUID.EAX = 8000000AH (* INVALID: Returns same information as CPUID.EAX = 0AH. *)
```

When CPUID returns the highest basic leaf information as a result of an invalid input EAX value, any dependence on input ECX value in the basic leaf is honored.

CPUID can be executed at any privilege level to serialize instruction execution. Serializing instruction execution guarantees that any modifications to flags, registers, and memory for previous instructions are completed before the next instruction is fetched and executed.

**See also:**

“Serializing Instructions” in Chapter 9, “Multiple-Processor Management,” in the Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A.

“Caching Translation Information” in Chapter 4, “Paging,” in the Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A.

</tbody>
</table>

1. On Intel 64 processors, CPUID clears the high 32 bits of the RAX/RBX/RCX/RDX registers in all modes.
2. CPUID leaf 1FH is a preferred superset to leaf 0BH. Intel recommends first checking for the existence of CPUID leaf 1FH before using leaf 0BH.

| 01H               | **NOTES:**  
|                   | * The nearest power-of-2 integer that is not smaller than EBX[23:16] is the maximum number of unique initial APIC IDs reserved for addressing different logical processors in a physical package.  
|                   | **The 8-bit initial APIC ID in EBX[31:24] is replaced by the 32-bit x2APIC ID, available in Leaf 0BH and Leaf 1FH.  
| EAX               | Version Information: Type, Family, Model, and Stepping ID (see Figure 1-1)  
| EBX               | Bits 7-0: Brand Index  
|                   | Bits 15-8: CLFLUSH line size (Value ∗ B = cache line size in bytes)  
|                   | Bits 23-16: Maximum number of addressable IDs for logical processors in this physical package*.  
|                   | Bits 31-24: Initial APIC ID**  
| ECX               | Feature Information (see Figure 1-2 and Table 1-5)  
| EDX               | Feature Information (see Figure 1-3 and Table 1-6)  

|02H| EAX | Cache and TLB Information (see Table 1-7) |
|EBX | Cache and TLB Information |
|ECX | Cache and TLB Information |
|EDX | Cache and TLB Information |

|03H| EAX | Reserved |
|EBX | Reserved |
|ECX | Bits 00-31 of 96 bit processor serial number. (Available in Pentium III processor only; otherwise, the value in this register is reserved.) |
|EDX | Bits 32-63 of 96 bit processor serial number. (Available in Pentium III processor only; otherwise, the value in this register is reserved.) |

**NOTES:**  
Processor serial number (PSN) is not supported in the Pentium 4 processor or later. On all models, use the PSN flag (returned using CPUID) to check for PSN support before accessing the feature.  
CPUID leaves > 3 < 80000000 are visible only when IA32_MISC_ENABLES.BOOT_NT4[bit 22] = 0 (default).  

**Deterministic Cache Parameters Leaf (Initial EAX Value = 04H)**

|04H| EAX | Bits 4-0: Cache Type Field  
|   |     | 0 = Null - No more caches  
|   |     | 1 = Data Cache  
|   |     | 2 = Instruction Cache  
|   |     | 3 = Unified Cache  
|   |     | 4-31 = Reserved  
|   | Bits 7-5: Cache Level (starts at 1)  
|   | Bits 8: Self Initializing cache level (does not need SW initialization)  
|   | Bits 9: Fully Associative cache  
|   | Bits 13-10: Reserved  
|   | Bits 25-14: Maximum number of addressable IDs for logical processors sharing this cache*, **  
|   | Bits 31-26: Maximum number of addressable IDs for processor cores in the physical package*; **; ***; ****  
| EBX | Bits 11-00: L = System Coherency Line Size*  
|     | Bits 21-12: P = Physical Line partitions*  
|     | Bits 31-22: W = Ways of associativity*

| EDX               | Bits 7-0: Bitmap of supported hardware feedback interface capabilities.  
|                   | 0 = when set to 1, indicates support for performance capability reporting.  
|                   | 1 = when set to 1, indicates support for energy efficiency capability reporting.  
|                   | 2-7 = Reserved  
| Bits 11-08: Enumerates the size of the hardware feedback interface structure in number of 4 KB pages; add one to the return value to get the result.  
| Bits 31-16: Index (starting at 0) of this logical processor's row in the hardware feedback interface structure. Note that on some parts the index may be same for multiple logical processors. On some parts the indices may not be contiguous, i.e., there may be unused rows in the hardware feedback interface structure.  
| **NOTE:** | Bits 0 and 1 will always be set together. |

**Structured Extended Feature Flags Enumeration Main Leaf (Initial EAX Value = 07H, ECX = 0)**

| EAX | NOTES:  
|-----|----------------------------------------|
| 07H | If ECX contains an invalid sub leaf index, EAX/EBX/ECX/EDX return 0. Sub-leaf index n is invalid if n exceeds the value that sub-leaf 0 returns in EAX.  
| EBX | Bits 31-00: Reports the maximum number sub-leaves that are supported in leaf 07H.  
|     | Bit 00: FSGSBASE. Supports RDFSBASE/RDGSBASE/WRFSGBASE/WRGSBASE if 1.  
|     | Bit 01: IA32_TSC_ADJUST MSR is supported if 1.  
|     | Bit 02: SGX  
|     | Bit 03: BMI1  
|     | Bit 04: HLE  
|     | Bit 05: AVX2: Supports Intel® Advanced Vector Extensions 2 (Intel® AVX2) if 1.  
|     | Bit 06: FDP_EXCPNT_ONLY. x87 FPU Data Pointer updated only on x87 exceptions if 1.  
|     | Bit 07: SMEP: Supports Supervisor Mode Execution Protection if 1.  
|     | Bit 08: BMI2  
|     | Bit 09: Supports Enhanced REP MOVSB/STOSB if 1.  
|     | Bit 10: INVPCID  
|     | Bit 11: RTM  
|     | Bit 13: Deprecates FPU CS and FPU DS values if 1.  
|     | Bit 14: Intel® Memory Protection Extensions  
|     | Bit 16: AVX512F  
|     | Bit 17: AVX512DQ

</thead>
</table>
| **ECX** | Bit 00: PREFETCHWT1 (Intel® Xeon Phi™ only.)  
Bit 01: AVX512_VBMI  
Bit 02: UMIP. Supports user-mode instruction prevention if 1.  
Bit 03: PKU. Supports protection keys for user-mode pages if 1.  
Bit 04: OSPKE. If 1, OS has set CR4.PKE to enable protection keys (and the RDPKRU/WRPKRU instructions).  
Bit 05: WAITPKG  
Bit 06: AVX512_VBMI2  
Bit 07: CET_SS. Supports CET shadow stack features if 1. Processors that set this bit define bits 1:0 of the IA32_U_CET and IA32_S_CET MSRs. Enumerates support for the following MSRs: IA32_INTERRUPT_SPP_TABLE_ADDR, IA32_PL3_SSP, IA32_PL2_SSP, IA32_PL1_SSP, and IA32_PL0_SSP.  
Bit 08: GFNI  
Bit 09: VAES  
Bit 10: VPCLMULQDQ  
Bit 11: AVX512_VNNI  
Bit 12: AVX512_BITALG  
Bit 13: TME_EN. If 1, the following MSRs are supported: IA32_TME_CAPABILITY, IA32_TME_ACTIVATE, IA32_TME_EXCLUDE_MASK, and IA32_TME_EXCLUDE_BASE.  
Bit 14: AVX512_VPOPCNTDQ  
Bit 15: Reserved  
Bit 16: IA57. Supports 57-bit linear addresses and five-level paging if 1.  
Bits 21-17: The value of MAWAU used by the BNDLDX and BNDSTX instructions in 64-bit mode.  
Bit 22: RDPID and IA32_TSC_AUX are available if 1.  
Bit 23: KL. Supports Key Locker if 1.  
Bit 24: BUS_LOCK_DETECT. If 1, indicates support for bus lock debug exceptions.  
Bit 25: CLDEMOTE. Supports cache line demote if 1.  
Bit 26: Reserved  
Bit 27: MOVDIRI. Supports MOVDIRI if 1.  
Bit 28: MOVDIR64B. Supports MOVDIR64B if 1.  
Bit 30: SGX_LC. Supports SGX Launch Configuration if 1.  
Bit 31: PKS. Supports protection keys for supervisor-mode pages if 1. |
| **EDX** | Bit 00: Reserved.  
Bit 01: SGX-KEYS. If 1, Attestation Services for Intel® SGX is supported.  
Bit 02: AVX512_4VNNIW (Intel® Xeon Phi™ only.)  
Bit 03: AVX512_4FMAPS (Intel® Xeon Phi™ only.)  
Bit 04: Fast Short REP MOV  
Bit 05: UINTR. If 1, the processor supports user interrupts.  
Bits 07-06: Reserved  
Bit 08: AVX512_VP2INTERSECT  
Bit 09: SRBDS_CTRL. If 1, enumerates support for the IA32_MCU_OPT_CTRL MSR and indicates that its bit 0 (RINGDS/MITG_DIS) is also supported.  
Bit 10: MD_CLEAR supported.  
Bit 11: RTM_ALWAYS_ABORT. If set, any execution of XBEGIN immediately aborts and transitions to the specified fallback address.  
Bit 12: Reserved  
Bit 13: If 1, RTM_FORCE_ABORT supported. Processors that set this bit support the TSX_FORCE_ABORT MSR. They allow software to set TSX_FORCE_ABORT[0] (RTM_FORCE_ABORT).  
Bit 14: SERIALIZE  
Bit 15: Hybrid. If 1, the processor is identified as a hybrid part. If CPUID.0.MAXLEAF ≥ 1AH and CPUID.1A.EAX ≠ 0, then the Native Model ID Enumeration Leaf 1AH exists.  
Bit 16: TSXLDTRK. If 1, the processor supports Intel TSX suspend/resume of load address tracking.  
Bit 17: Reserved |

### Extended Topology Enumeration Leaf (Initial EAX Value = 0BH)

<table>
<thead>
<tr>
<th>Hierarchy</th>
<th>Domain Type Identification Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Lowest</td>
<td>Logical Processor 1</td>
</tr>
<tr>
<td>Highest</td>
<td>Core 2</td>
</tr>
</tbody>
</table>

(No specification of enumeration values of 0 and 3-255 are reserved.)

**NOTES:**

CPUID leaf 1FH is a preferred superset to leaf 0BH. Intel recommends first checking for the existence of Leaf 1FH before using leaf 0BH.

The sub-leaves of CPUID leaf 0BH describe an ordered hierarchy of logical processors starting from the smallest-scoped domain of a Logical Processor (subleaf index 0) to the Core domain (subleaf index 1) to the largest-scoped domain (the last valid subleaf index) that is implicitly subordinate to the unenumerated highest-scoped domain of the processor package (socket).

The details of each valid domain is enumerated by a corresponding subleaf. Details for a domain include its type and how all instances of that domain determine the number of logical processors and x2APIC ID partitioning at the next higher-scoped domain. The ordering of domains within the hierarchy is fixed architecturally as shown below. For a given processor, not all domains may be relevant or enumerated; however, the logical processor and core domains are always enumerated.

For two valid sub-leaves N and N+1, sub-leaf N+1 represents the next immediate higher-scoped domain with respect to the domain of sub-leaf N for the given processor.

If subleaf index “N” returns an invalid domain type in ECX[15:08] (00H), then all sub-leaves with an index greater than “N” shall also return an invalid domain type. A sub-leaf returning an invalid domain always returns 0 in EAX and EBX.

Bits 04-00: The number of bits that the x2APIC ID must be shifted to the right to address instances of the next higher-scoped domain. When logical processor is not supported by the processor, the value of this field at the Logical Processor domain subleaf may be returned as either 0 (no allocated bits in the x2APIC ID) or 1 (one allocated bit in the x2APIC ID); software should plan accordingly. Bits 31-05: Reserved.

Bits 15-00: The number of logical processors across all instances of this domain within the next higher-scoped domain. (For example, in a processor socket/package comprising “M” dies of “N” cores each, where each core has “L” logical processors, the “die” domain subleaf value of this field would be M*N*L. This number reflects configuration as shipped by Intel. Note, software must not use this field to enumerate processor topology*.

Bits 31-16: Reserved.

Intel® Resource Director Technology (Intel® RDT) Allocation Enumeration Sub-leaf (Initial EAX Value = 10H, ECX = 0)

10H

NOTES:

Leaf 10H output depends on the initial value in ECX.

Sub-leaf index 0 reports valid resource identification (ResID) starting at bit position 1 of EBX.

EAX Reserved.

EBX Bit 00: Reserved.

Bit 01: Supports L3 Cache Allocation Technology if 1.

Bit 02: Supports L2 Cache Allocation Technology if 1.

Bit 03: Supports Memory Bandwidth Allocation if 1.

Bits 31-04: Reserved.

ECX Reserved.

EDX Reserved.

L3 Cache Allocation Technology Enumeration Sub-leaf (Initial EAX Value = 10H, ECX = ResID =1)

10H

NOTES:

Leaf 10H output depends on the initial value in ECX.

EAX Bits 04-00: Length of the capacity bit mask for the corresponding ResID using minus-one notation.

Bits 31-05: Reserved

EBX Bits 31-00: Bit-granular map of isolation/contention of allocation units.

ECX Bit 00: Reserved.

Bit 01: Updates of COS should be infrequent if 1.

Bit 02: Code and Data Prioritization Technology supported if 1.

Bit 03: Non-contiguous 1s value supported if 1.

Bits 31-04: Reserved.

EDX Bits 15-00: Highest COS number supported for this ResID.

Bits 31-16: Reserved.

</table>

<table>
<thead>
<tr>
<th>Type 0001b. This sub-leaf enumerates an EPC sections with EDX:ECX, EBX:EAX defined as follows.</th>
</tr>
</thead>
<tbody>
<tr>
<td>EAX[11:04]: Reserved (enumerate 0).</td>
</tr>
<tr>
<td>EAX[31:12]: Bits 31:12 of the physical address of the base of the EPC section.</td>
</tr>
<tr>
<td>EBX[19:00]: Bits 51:32 of the physical address of the base of the EPC section.</td>
</tr>
<tr>
<td>EBX[31:20]: Reserved.</td>
</tr>
</tbody>
</table>

ECX[03:00]: EPC section property encoding defined as follows:
- If EAX[3:0] 0000b, then all bits of the EDX:ECX pair are enumerated as 0.
- If EAX[3:0] 0001b, then this section has confidentiality and integrity protection.
- If EAX[3:0] 0010b, then this section has confidentiality protection only.
- All other encodings are reserved.

<table>
<thead>
<tr>
<th>ECX[11:04]: Reserved (enumerate 0).</th>
</tr>
</thead>
<tbody>
<tr>
<td>ECX[31:12]: Bits 31:12 of the size of the corresponding EPC section within the Processor Reserved Memory.</td>
</tr>
</tbody>
</table>

EDX[19:00]: Bits 51:32 of the size of the corresponding EPC section within the Processor Reserved Memory.

EDX[31:20]: Reserved.

### Intel® Processor Trace Enumeration Main Leaf (Initial EAX Value = 14H, ECX = 0)

<table>
<thead>
<tr>
<th>Initial EAX Value</th>
<th>Information Provided about the Processor</th>
</tr>
</thead>
<tbody>
<tr>
<td>14H</td>
<td>Leaf 14H main leaf (ECX = 0).</td>
</tr>
</tbody>
</table>

| EAX Bit 31-00: Reports the maximum sub-leaf supported in leaf 14H. |
### Table 1-3. Information Returned by CPUID Instruction (Continued)

<table>
<thead>
<tr>
<th>Initial EAX Value</th>
<th>Information Provided about the Processor</th>
</tr>
</thead>
</table>
| EBX               | Bit 00: If 1, indicates that IA32_RTIT_CTL.CR3Filter can be set to 1, and that IA32_RTIT_CR3_MATCH MSR can be accessed.  
Bits 01: If 1, indicates support of Configurable PSB and Cycle-Accurate Mode.  
Bits 02: If 1, indicates support of IP Filtering, TraceStop filtering, and preservation of Intel PT MSRs across warm reset.  
Bits 03: If 1, indicates support of MTC timing packet and suppression of COFI-based packets.  
Bit 04: If 1, indicates support of PTWRITE. Writes can set IA32_RTIT_CTL[12] (PTWEn) and IA32_RTIT_CTL[5] (FUPonPTW), and PTWRITE can generate packets.  
Bit 05: If 1, indicates support of Power Event Trace. Writes can set IA32_RTIT_CTL[4] (PwrEvtEn), enabling Power Event Trace packet generation.  
Bit 06: If 1, indicates support for PSB and PMI preservation. Writes can set IA32_RTIT_CTL[56] (InjectPsbPmiOnEnable), enabling the processor to set IA32_RTIT_STATUS[7] (PendTopaPMI) and/or IA32_RTIT_STATUS[6] (PendPSB) in order to preserve ToPA PMIs and/or PSBs otherwise lost due to Intel PT disable. Writes can also set PendToPAPMI and PendPSB.  
Bit 07: If 1, writes can set IA32_RTIT_CTL[31] (EventEn), enabling Event Trace packet generation.  
Bit 08: If 1, writes can set IA32_RTIT_CTL[55] (DisTNT), disabling TNT packet generation.  
Bits 31-09: Reserved. |
| ECX               | Bit 00: If 1, Tracing can be enabled with IA32_RTIT_CTL.ToPA = 1, hence utilizing the ToPA output scheme: IA32_RTIT_OUTPUT_BASE and IA32_RTIT_OUTPUT_MASK_PTRS MSRs can be accessed.  
Bit 01: If 1, ToPA tables can hold any number of output entries, up to the maximum allowed by the MaskOrTableOffset field of IA32_RTIT_OUTPUT_MASK_PTRS.  
Bits 02: If 1, indicates support of Single-Range Output scheme.  
Bits 03: If 1, indicates support of output to Trace Transport subsystem.  
Bit 30-04: Reserved.  
Bit 31: If 1, generated packets which contain IP payloads have LIP values, which include the CS base component. |
| EDX               | Bits 31-00: Reserved. |

### Intel Processor Trace Enumeration Sub-leaf (Initial EAX Value = 14H, ECX = 1)

| 14H EAX | Bits 02-00: Number of configurable Address Ranges for filtering.  
Bits 15-03: Reserved.  
Bit 31-16: Bitmap of supported MTC period encodings. |
|--------------------------|--------------------------|
| 14H EBX | Bits 15-00: Bitmap of supported Cycle Threshold value encodings.  
Bit 31-16: Bitmap of supported Configurable PSB frequency encodings. |
| 14H ECX | Bits 31-00: Reserved. |
| 14H EDX | Bits 31-00: Reserved. |

### Time Stamp Counter and Core Crystal Clock Information Leaf (Initial EAX Value = 15H)

**NOTES:**  
If EBX[31:0] is 0, the TSC and “core crystal clock” ratio is not enumerated.  
EBX[31:0]/EAX[31:0] indicates the ratio of the TSC frequency and the core crystal clock frequency.  
If ECX is 0, the core crystal clock frequency is not enumerated.  
“TSC frequency” = “core crystal clock frequency” * EBX/EAX.  
The core crystal clock may differ from the reference clock, bus clock, or core clock frequencies.  

<table>
<thead>
<tr>
<th>15H EAX</th>
<th>Bits 31-00: An unsigned integer which is the denominator of the TSC/“core crystal clock” ratio.</th>
</tr>
</thead>
<tbody>
<tr>
<td>15H EBX</td>
<td>Bits 31-00: An unsigned integer which is the numerator of the TSC/“core crystal clock” ratio.</td>
</tr>
<tr>
<td>15H ECX</td>
<td>Bits 31-00: An unsigned integer which is the nominal frequency of the core crystal clock in Hz.</td>
</tr>
<tr>
<td>15H EDX</td>
<td>Bits 31-00: Reserved = 0.</td>
</tr>
</tbody>
</table>

<td>Bits 15-00: Maximum Frequency (in MHz). Bits 31-16: Reserved = 0</td>
</tr>
<tr>
<td>ECX</td>
<td>Bits 15-00: Bus (Reference) Frequency (in MHz). Bits 31-16: Reserved = 0</td>
</tr>
<tr>
<td>EDX</td>
<td>Reserved</td>
</tr>
</tbody>
</table>

**NOTES:**
* Data is returned from this interface in accordance with the processor’s specification and does not reflect actual values. Suitable use of this data includes the display of processor information in like manner to the processor brand string and for determining the appropriate range to use when displaying processor information e.g. frequency history graphs. The returned information should not be used for any other purpose as the returned information does not accurately correlate to information / counters returned by other processor interfaces.

While a processor may support the Processor Frequency Information leaf, fields that return a value of zero are not supported.

| **System-On-Chip Vendor Attribute Enumeration Main Leaf (Initial EAX Value = 17H, ECX = 0)** |
| 17H | **NOTES:** |
| EAX | Leaf 17H main leaf (ECX = 0). Leaf 17H output depends on the initial value in ECX. Leaf 17H sub-leaves 1 through 3 reports SOC Vendor Brand String. Leaf 17H is valid if MaxSOCID_Index >= 3. Leaf 17H sub-leaves 4 and above are reserved. |
| EBX | Bits 15-00: SOC Vendor ID. Bit 16: IsVendorScheme. If 1, the SOC Vendor ID field is assigned via an industry standard enumeration scheme. Otherwise, the SOC Vendor ID field is assigned by Intel. Bits 31-17: Reserved = 0. |
| ECX | Bits 31-00: Project ID. A unique number an SOC vendor assigns to its SOC projects. |
| EDX | Bits 31-00: Stepping ID. A unique number within an SOC project that an SOC vendor assigns. |

| **System-On-Chip Vendor Attribute Enumeration Sub-leaf (Initial EAX Value = 17H, ECX > MaxSOCID_Index)** |
| 17H | **NOTES:** |
| EAX | Bit 31-00: SOC Vendor Brand String. UTF-8 encoded string. |
| EBX | Bit 31-00: SOC Vendor Brand String. UTF-8 encoded string. |
| ECX | Bit 31-00: SOC Vendor Brand String. UTF-8 encoded string. |
| EDX | Bit 31-00: SOC Vendor Brand String. UTF-8 encoded string. |

**NOTES:**
- Leaf 17H output depends on the initial value in ECX.
- SOC Vendor Brand String is a UTF-8 encoded string padded with trailing bytes of 00H.
- The complete SOC Vendor Brand String is constructed by concatenating in ascending order of EAX:EBX:ECX:EDX and from the sub-leaf 1 fragment towards sub-leaf 3.

| **System-On-Chip Vendor Attribute Enumeration Sub-leaves (Initial EAX Value = 17H, ECX > MaxSOCID_Index)** |
| 17H | **NOTES:** |
| EAX | Leaf 17H output depends on the initial value in ECX. |

Deterministic Address Translation Parameters Main Leaf (Initial EAX Value = 18H, ECX = 0)

**NOTES:**
- Each sub-leaf enumerates a different address translations structure.
- If ECX contains an invalid sub-leaf index, EAX/EBX/ECX/EDX return 0. Sub-leaf index n is invalid if n exceeds the value that sub-leaf 0 returns in EAX. A sub-leaf index is also invalid if EDX[4:0] returns 0. Valid sub-leaves do not need to be contiguous or in any particular order. A valid sub-leaf may be in a higher input ECX value than an invalid sub-leaf or than a valid sub-leaf of a higher or lower-level structure.
- * Some unified TLBs will allow a single TLB entry to satisfy data read/write and instruction fetches. Others will require separate entries (e.g., one loaded on data read/write and another loaded on an instruction fetch). See the Intel® 64 and IA-32 Architectures Optimization Reference Manual for details of a particular product.
- ** Add one to the return value to get the result.

### Deterministic Address Translation Parameters Sub-leaf (Initial EAX Value = 18H, ECX ≥ 1)

**NOTES:**
- If ECX contains an invalid sub-leaf index, EAX/EBX/ECX/EDX return 0. Sub-leaf index n is invalid if n exceeds the value that sub-leaf 0 returns in EAX. A sub-leaf index is also invalid if EDX[4:0] returns 0. Valid sub-leaves do not need to be contiguous or in any particular order. A valid sub-leaf may be in a higher input ECX value than an invalid sub-leaf or than a valid sub-leaf of a higher or lower-level structure.
- Some unified TLBs will allow a single TLB entry to satisfy data read/write and instruction fetches. Others will require separate entries (e.g., one loaded on data read/write and another loaded on an instruction fetch). See the Intel® 64 and IA-32 Architectures Optimization Reference Manual for details of a particular product.
- **Add one to the return value to get the result.

V2 Extended Topology Enumeration Leaf (Initial EAX Value = 1FH)

**NOTES:**

CPUID leaf 1FH is a preferred superset to leaf 0BH. Intel recommends using leaf 1FH when available rather than leaf 0BH and ensuring that any leaf 0BH algorithms are updated to support leaf 1FH.

The sub-leaves of CPUID leaf 1FH describe an ordered hierarchy of logical processors starting from the smallest-scoped domain of a Logical Processor (sub-leaf index 0) to the Core domain (sub-leaf index 1) to the largest-scoped domain (the last valid sub-leaf index) that is implicitly subordinate to the unenumerated highest-scoped domain of the processor package (socket).

The details of each valid domain is enumerated by a corresponding sub-leaf. Details for a domain include its type and how all instances of that domain determine the number of logical processors and x2 APIC ID partitioning at the next higher-scoped domain. The ordering of domains within the hierarchy is fixed architecturally as shown below. For a given processor, not all domains may be relevant or enumerated; however, the logical processor and core domains are always enumerated. As an example, a processor may report an ordered hierarchy consisting only of “Logical Processor,” “Core,” and “Die.”

For two valid sub-leaves N and N+1, sub-leaf N+1 represents the next immediate higher-scoped domain with respect to the domain of sub-leaf N for the given processor.

If sub-leaf index “N” returns an invalid domain type in ECX[15:08] (00H), then all sub-leaves with an index greater than “N” shall also return an invalid domain type. A sub-leaf returning an invalid domain always returns 0 in EAX and EBX.

<table>
<thead>
<tr>
<th>EAX</th>
<th>Bits 04-00: The number of bits that the x2APIC ID must be shifted to the right to address instances of the next higher-scoped domain. When logical processor is not supported by the processor, the value of this field at the Logical Processor domain sub-leaf may be returned as either 0 (no allocated bits in the x2APIC ID) or 1 (one allocated bit in the x2APIC ID); software should plan accordingly. Bits 31-05: Reserved.</th>
</tr>
</thead>
<tbody>
<tr>
<td>EBX</td>
<td>Bits 15-00: The number of logical processors across all instances of this domain within the next higher-scoped domain relative to this current logical processor. (For example, in a processor socket/package symmetric topology comprising “M” dies of “N” cores each, where each core has “L” logical processors, the “die” domain sub-leaf value of this field would be M<em>N</em>L. In an asymmetric topology this would be the summation of the value across the lower domain level instances to create each upper domain level instance.) This number reflects configuration as shipped by Intel. Note, software must not use this field to enumerate processor topology*. Bits 31-16: Reserved.</td>
</tr>
<tr>
<td>Initial EAX Value</td>
<td>Information Provided about the Processor</td>
</tr>
<tr>
<td>-------------------</td>
<td>----------------------------------------</td>
</tr>
<tr>
<td>ECX</td>
<td>Bits 07-00: The input ECX sub-leaf index. Bits 15-08: Domain Type. This field provides an identification value which indicates the domain as shown below. Although domains are ordered, as also shown below, their assigned identification values are not and software should not depend on it. (For example, if a new domain between core and module is specified, it will have an identification value higher than 5.)</td>
</tr>
</tbody>

(Note that enumeration values of 0 and 7-255 are reserved.)

| EDX       | Bits 31-00: x2APIC ID of the current logical processor. It is always valid and does not vary with the sub-leaf index in ECX. |

**NOTES:**

* Software must not use the value of EBX[15:0] to enumerate processor topology of the system. The value is only intended for display and diagnostic purposes. The actual number of logical processors available to BIOS/OS/Applications may be different from the value of EBX[15:0], depending on software and platform hardware configurations.

**NOTES:**
* If CPUID.80000008H:EAX[7:0] is supported, the maximum physical address number supported should come from this field.

INPUT EAX = 0H: Returns CPUID’s Highest Value for Basic Processor Information and the Vendor Identification String

When CPUID executes with EAX set to 0H, the processor returns the highest value the CPUID recognizes for returning basic processor information. The value is returned in the EAX register and is processor specific.

A vendor identification string is also returned in EBX, EDX, and ECX. For Intel processors, the string is "GenuineIntel" and is expressed:

   EBX := 756e6547h (* "Genu", with G in the low 4 bits of BL *)
   EDX := 49656e69h (* "intel", with i in the low 4 bits of DL *)
   ECX := 6c65746eh (* "ntel", with n in the low 4 bits of CL *)

INPUT EAX = 80000000H: Returns CPUID’s Highest Value for Extended Processor Information

When CPUID executes with EAX set to 0H, the processor returns the highest value the processor recognizes for returning extended processor information. The value is returned in the EAX register and is processor specific.
IA32_BIOS_SIGN_ID Returns Microcode Update Signature

For processors that support the microcode update facility, the IA32_BIOS_SIGN_ID MSR is loaded with the update signature whenever CPUID executes. The signature is returned in the upper DWORD. For details, see Chapter 11 in the Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A.

INPUT EAX = 01H: Returns Model, Family, Stepping Information

When CPUID executes with EAX set to 01H, version information is returned in EAX (see Figure 1-1). For example: model, family, and processor type for the Intel Xeon processor 5100 series is as follows:

- Model — 1111B
- Family — 0101B
- Processor Type — 00B

See Table 1-4 for available processor type values. Stepping IDs are provided as needed.

![Figure 1-1. Version Information Returned by CPUID in EAX](image)

<tr>
<td>Intel reserved</td>
<td>11B</td>
</tr>
</tbody>
</table>

NOTE

The Extended Family ID needs to be examined only when the Family ID is 0FH. Integrate the fields into a display using the following rule:

IF Family_ID ≠ 0FH
    THEN Displayed_Family = Family_ID;
    ELSE Displayed_Family = Extended_Family_ID + Family_ID;
FI;
The Extended Model ID needs to be examined only when the Family ID is 06H or 0FH. Integrate the field into a display using the following rule:

IF (Family_ID = 06H or Family_ID = 0FH)
THEN Displayed_Model = (Extended_Model_ID << 4) + Model_ID;
ELSE Displayed_Model = Model_ID;
FI;

INPUT EAX = 01H: Returns Additional Information in EBX

When CPUID executes with EAX set to 01H, additional information is returned to the EBX register:

• Brand index (low byte of EBX) — this number provides an entry into a brand string table that contains brand strings for IA-32 processors. More information about this field is provided later in this section.
• CLFLUSH instruction cache line size (second byte of EBX) — this number indicates the size of the cache line flushed with CLFLUSH instruction in 8-byte increments. This field was introduced in the Pentium 4 processor.
• Local APIC ID (high byte of EBX) — this number is the 8-bit ID that is assigned to the local APIC on the processor during power up. This field was introduced in the Pentium 4 processor.

INPUT EAX = 01H: Returns Feature Information in ECX and EDX

When CPUID executes with EAX set to 01H, feature information is returned in ECX and EDX.

• Figure 1-2 and Table 1-5 show encodings for ECX.
• Figure 1-3 and Table 1-6 show encodings for EDX.

For all feature flags, a 1 indicates that the feature is supported. Use Intel to properly interpret feature flags.

NOTE
Software must confirm that a processor feature is present using feature flags returned by CPUID prior to using the feature. Software should not depend on future offerings retaining all features.

</table>
### FUTURE INTEL® ARCHITECTURE INSTRUCTION EXTENSIONS AND FEATURES

**6 PAE**

Physical Address Extension. Physical addresses greater than 32 bits are supported: extended page table entry formats, an extra level in the page translation tables is defined, 2-MByte pages are supported instead of 4 MByte pages if PAE bit is 1. The actual number of address bits beyond 32 is not defined, and is implementation specific.

**7 MCE**

Machine Check Exception. Exception 18 is defined for Machine Checks, including CR4.MCE for controlling the feature. This feature does not define the model-specific implementations of machine-check error logging, reporting, and processor shutdowns. Machine Check exception handlers may have to depend on processor version to do model specific processing of the exception, or test for the presence of the Machine Check feature.

**8 CX8**

CMPXCHG8B Instruction. The compare-and-exchange 8 bytes (64 bits) instruction is supported (implicitly locked and atomic).

**9 APIC**

APIC On-Chip. The processor contains an Advanced Programmable Interrupt Controller (APIC), responding to memory mapped commands in the physical address range FFFE0000H to FFFE0FFFH (by default - some processors permit the APIC to be relocated).

**10 Reserved**

Reserved

**11 SEP**

SYSENTER and SYSEXIT Instructions. The SYSENTER and SYSEXIT and associated MSRs are supported.

**12 MTRR**

Memory Type Range Registers. MTRRs are supported. The MTRRcap MSR contains feature bits that describe what memory types are supported, how many variable MTRRs are supported, and whether fixed MTRRs are supported.

**13 PGE**

Page Global Bit. The global bit is supported in paging-structure entries that map a page, indicating TLB entries that are common to different processes and need not be flushed. The CR4.PGE bit controls this feature.

**14 MCA**

Machine Check Architecture. The Machine Check Architecture, which provides a compatible mechanism for error reporting in P6 family, Pentium 4, Intel Xeon processors, and future processors, is supported. The MCG_CAP MSR contains feature bits describing how many banks of error reporting MSRs are supported.

**15 CMOV**

Conditional Move Instructions. The conditional move instruction CMOV is supported. In addition, if x87 FPU is present as indicated by the CPUID.FPU feature bit, then the FCOMI and FCMOV instructions are supported.

**16 PAT**

Page Attribute Table. Page Attribute Table is supported. This feature augments the Memory Type Range Registers (MTRRs), allowing an operating system to specify attributes of memory accessed through a linear address on a 4KB granularity.

**17 PSE-36**

36-Bit Page Size Extension. 4-MByte pages addressing physical memory beyond 4 GBytes are supported with 32-bit paging. This feature indicates that upper bits of the physical address of a 4-MByte page are encoded in bits 20:13 of the page-directory entry. Such physical addresses are limited by MAXPHYADDR and may be up to 40 bits in size.

**18 PSN**

Processor Serial Number. The processor supports the 96-bit processor identification number feature and the feature is enabled.

**19 CLFSH**

CLFLUSH Instruction. CLFLUSH Instruction is supported.

**20 Reserved**

Reserved

**21 DS**

Debug Store. The processor supports the ability to write debug information into a memory resident buffer. This feature is used by the branch trace store (BTS) and precise event-based sampling (PEBS) facilities (see Chapter 24, “Introduction to Virtual-Machine Extensions,” in the Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3C).

**22 ACPI**

Thermal Monitor and Software Controlled Clock Facilities. The processor implements internal MSRs that allow processor temperature to be monitored and processor performance to be modulated in predefined duty cycles under software control.

**23 MMX**

Intel MMX Technology. The processor supports the Intel MMX technology.

**24 FXSR**

FXSAVE and FXRSTOR Instructions. The FXSAVE and FXRSTOR instructions are supported for fast save and restore of the floating-point context. Presence of this bit also indicates that CR4.OSFXSR is available for an operating system to indicate that it supports the FXSAVE and FXRSTOR instructions.

</tr>
</tbody>
</table>
When CPUID executes with EAX set to 02H, the processor returns information about the processor's internal caches and TLBs in the EAX, EBX, ECX, and EDX registers.

The encoding is as follows:

- The least-significant byte in register EAX (register AL) indicates the number of times the CPUID instruction must be executed with an input value of 02H to get a complete description of the processor's caches and TLBs. The first member of the family of Pentium 4 processors will return a 01H.
- The most significant bit (bit 31) of each register indicates whether the register contains valid information (set to 0) or is reserved (set to 1).
- If a register contains valid information, the information is contained in 1 byte descriptors. Table 1-7 shows the encoding of these descriptors. Note that the order of descriptors in the EAX, EBX, ECX, and EDX registers is not defined; that is, specific bytes are not designated to contain descriptors for specific cache or TLB types. The descriptors may appear in any order.

</table>
Example 1-1. Example of Cache and TLB Interpretation

The first member of the family of Pentium 4 processors returns the following information about caches and TLBs when the CPUID executes with an input value of 2:

\[
\begin{align*}
EAX & = 66\ 5B\ 50\ 01H \\
EBX & = 0H \\
ECX & = 0H \\
EDX & = 00\ 7A\ 70\ 00H \\
\end{align*}
\]

Which means:

- The least-significant byte (byte 0) of register EAX is set to 01H. This indicates that CPUID needs to be executed once with an input value of 2 to retrieve complete information about caches and TLBs.
- The most-significant bit of all four registers (EAX, EBX, ECX, and EDX) is set to 0, indicating that each register contains valid 1-byte descriptors.
- Bytes 1, 2, and 3 of register EAX indicate that the processor has:
  - 50H - a 64-entry instruction TLB, for mapping 4-KByte and 2-MByte or 4-MByte pages.
  - 5BH - a 64-entry data TLB, for mapping 4-KByte and 4-MByte pages.
  - 66H - an 8-KByte 1st level data cache, 4-way set associative, with a 64-Byte cache line size.
- The descriptors in registers EBX and ECX are valid, but contain NULL descriptors.
- Bytes 0, 1, 2, and 3 of register EDX indicate that the processor has:
  - 00H - NULL descriptor.
  - 70H - Trace cache: 12 K-μop, 8-way set associative.
  - 7AH - a 256-KByte 2nd level cache, 8-way set associative, with a sectored, 64-byte cache line size.
  - 00H - NULL descriptor.

INPUT EAX = 04H: Returns Deterministic Cache Parameters for Each Level

When CPUID executes with EAX set to 04H and ECX contains an index value, the processor returns encoded data that describe a set of deterministic cache parameters (for the cache level associated with the input in ECX). Valid index values start from 0.

Software can enumerate the deterministic cache parameters for each level of the cache hierarchy starting with an index value of 0, until the parameters report the value associated with the cache type field is 0. The architecturally defined fields reported by deterministic cache parameters are documented in Table 1-3.
The CPUID leaf 4 also reports data that can be used to derive the topology of processor cores in a physical package. This information is constant for all valid index values. Software can query the raw data reported by executing CPUID with EAX=04H and ECX=0H and use it as part of the topology enumeration algorithm described in Chapter 9, “Multiple-Processor Management,” in the Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A.

**INPUT EAX = 05H: Returns MONITOR and MWAIT Features**

When CPUID executes with EAX set to 05H, the processor returns information about features available to MONITOR/MWAIT instructions. The MONITOR instruction is used for address-range monitoring in conjunction with MWAIT instruction. The MWAIT instruction optionally provides additional extensions for advanced power management. See Table 1-3.

**INPUT EAX = 06H: Returns Thermal and Power Management Features**

When CPUID executes with EAX set to 06H, the processor returns information about thermal and power management features. See Table 1-3.

**INPUT EAX = 07H: Returns Structured Extended Feature Enumeration Information**

When CPUID executes with EAX set to 07H and ECX = 0H, the processor returns information about the maximum number of sub-leaves that contain extended feature flags. See Table 1-3.

When CPUID executes with EAX set to 07H and ECX = n (n ≥ 1 and less than the number of non-zero bits in CPUID.(EAX=07H, ECX= 0H).EAX), the processor returns information about extended feature flags. See Table 1-3. In sub-leaf 0, only EAX has the number of sub-leaves. In sub-leaf 0, EBX, ECX & EDX all contain extended feature flags.

**INPUT EAX = 09H: Returns Direct Cache Access Information**

When CPUID executes with EAX set to 09H, the processor returns information about Direct Cache Access capabilities. See Table 1-3.

**INPUT EAX = 0AH: Returns Architectural Performance Monitoring Features**

When CPUID executes with EAX set to 0AH, the processor returns information about support for architectural performance monitoring capabilities. Architectural performance monitoring is supported if the version ID (see Table 1-3) is greater than Pn 0. See Table 1-3.

For each version of architectural performance monitoring capability, software must enumerate this leaf to discover the programming facilities and the architectural performance events available in the processor. The details are described in Chapter 18, “Debug, Branch Profile, TSC, and Intel® Resource Director Technology (Intel® RDT) Features,” in the Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A.

**INPUT EAX = 0BH: Returns Extended Topology Information**

CPUID leaf 1FH is a preferred superset to leaf 0BH. Intel recommends first checking for the existence of Leaf 1FH before using leaf 0BH.

When CPUID executes with EAX set to 0BH, the processor returns information about extended topology enumeration data. Software must detect the presence of CPUID leaf 0BH by verifying (a) the highest leaf index supported by CPUID is >= 0BH, and (b) CPUID.0BH:EBX[15:0] reports a non-zero value. See Table 1-3.

**INPUT EAX = 0DH: Returns Processor Extended States Enumeration Information**

When CPUID executes with EAX set to 0DH and ECX = 0H, the processor returns information about the bit-vector representation of all processor state extensions that are supported in the processor and storage size requirements of the XSAVE/XRSTOR area. See Table 1-3.

When CPUID executes with EAX set to 0DH and ECX = n (n > 1, and is a valid sub-leaf index), the processor returns information about the size and offset of each processor extended state save area within the XSAVE/XRSTOR area.
See Table 1-3. Software can use the forward-extendable technique depicted below to query the valid sub-leaves and obtain size and offset information for each processor extended state save area:

For i = 2 to 62 // sub-leaf 1 is reserved
  IF (CPUID.(EAX=0DH, ECX=0):VECTOR[i] = 1) // VECTOR is the 64-bit value of EDX:EAX
    Execute CPUID.(EAX=0DH, ECX = i) to examine size and offset for sub-leaf i;
  FI;

INPUT EAX = 0FH: Returns Intel Resource Director Technology (Intel RDT) Monitoring Enumeration Information

When CPUID executes with EAX set to 0FH and ECX = 0, the processor returns information about the bit-vector representation of QoS monitoring resource types that are supported in the processor and maximum range of RMID values the processor can use to monitor any supported resource types. Each bit, starting from bit 1, corresponds to a specific resource type if the bit is set. The bit position corresponds to the sub-leaf index (or ResID) that software must use to query QoS monitoring capability available for that type. See Table 1-3.

When CPUID executes with EAX set to 0FH and ECX = n (n >= 1, and is a valid ResID), the processor returns information software can use to program IA32_PQR_ASSOC, IA32_QM_EVTSEL MSRs before reading QoS data from the IA32_QM_CTR MSR.

INPUT EAX = 10H: Returns Intel Resource Director Technology (Intel RDT) Allocation Enumeration Information

When CPUID executes with EAX set to 10H and ECX = 0, the processor returns information about the bit-vector representation of QoS Enforcement resource types that are supported in the processor. Each bit, starting from bit 1, corresponds to a specific resource type if the bit is set. The bit position corresponds to the sub-leaf index (or ResID) that software must use to query QoS enforcement capability available for that type. See Table 1-3.

When CPUID executes with EAX set to 10H and ECX = n (n >= 1, and is a valid ResID), the processor returns information about available classes of service and range of QoS mask MSRs that software can use to configure each class of services using capability bit masks in the QoS Mask registers, IA32_resourceType_Mask_n.

INPUT EAX = 12H: Returns Intel SGX Enumeration Information

When CPUID executes with EAX set to 12H and ECX = 0H, the processor returns information about Intel SGX capabilities. See Table 1-3.

When CPUID executes with EAX set to 12H and ECX = 1H, the processor returns information about Intel SGX attributes. See Table 1-3.

When CPUID executes with EAX set to 12H and ECX = n (n > 1), the processor returns information about Intel SGX Enclave Page Cache. See Table 1-3.

INPUT EAX = 14H: Returns Intel Processor Trace Enumeration Information

When CPUID executes with EAX set to 14H and ECX = 0H, the processor returns information about Intel Processor Trace extensions. See Table 1-3.

When CPUID executes with EAX set to 14H and ECX = n (n > 0 and less than the number of non-zero bits in CPUID.(EAX=14H, ECX= 0H).EAX), the processor returns information about packet generation in Intel Processor Trace. See Table 1-3.

INPUT EAX = 15H: Returns Time Stamp Counter and Nominal Core Crystal Clock Information

When CPUID executes with EAX set to 15H and ECX = 0H, the processor returns information about Time Stamp Counter and Core Crystal Clock. See Table 1-3.

INPUT EAX = 16H: Returns Processor Frequency Information

When CPUID executes with EAX set to 16H, the processor returns information about Processor Frequency Information. See Table 1-3.
FUTURE INTEL® ARCHITECTURE INSTRUCTION EXTENSIONS AND FEATURES

**INPUT EAX = 17H: Returns System-On-Chip Information**
When CPUID executes with EAX set to 17H, the processor returns information about the System-On-Chip Vendor Attribute Enumeration. See Table 1-3.

**INPUT EAX = 18H: Returns Deterministic Address Translation Parameters Information**
When CPUID executes with EAX set to 18H, the processor returns information about the Deterministic Address Translation Parameters. See Table 1-3.

**INPUT EAX = 19H: Returns Key Locker Information**
When CPUID executes with EAX set to 19H, the processor returns information about Key Locker. See Table 1-3.

**INPUT EAX = 1AH: Returns Hybrid Information**
When CPUID executes with EAX set to 1AH, the processor returns information about hybrid capabilities. See Table 1-3.

**INPUT EAX = 1BH: Returns PCONFIG Information**
When CPUID executes with EAX set to 1BH, the processor returns information about PCONFIG capabilities. See Table 1-3.

**INPUT EAX = 1CH: Returns Last Branch Record Information**
When CPUID executes with EAX set to 1CH, the processor returns information about LBRs (the architectural feature). See Table 1-3.

**INPUT EAX = 1DH: Returns Tile Information**
When CPUID executes with EAX set to 1DH and ECX = 0H, the processor returns information about tile architecture. See Table 1-3.
When CPUID executes with EAX set to 1DH and ECX = 1H, the processor returns information about tile palette 1. See Table 1-3.

**INPUT EAX = 1EH: Returns TMUL Information**
When CPUID executes with EAX set to 1EH and ECX = 0H, the processor returns information about TMUL capabilities. See Table 1-3.

**INPUT EAX = 1FH: Returns V2 Extended Topology Information**
When CPUID executes with EAX set to 1FH, the processor returns information about extended topology enumeration data. Software must detect the presence of CPUID leaf 1FH by verifying (a) the highest leaf index supported by CPUID is >= 1FH, and (b) CPUID.1FH:EBX[15:0] reports a non-zero value. See Table 1-3.

**INPUT EAX = 20H: Returns Processor History Reset Information**
When CPUID executes with EAX set to 20H, the processor returns information about processor history reset. See Table 1-3.

**INPUT EAX = 23H: Returns Architectural Performance Monitoring Extended Information**
When CPUID executes with EAX set to 23H, the processor returns architectural performance monitoring extended information. See Table 1-3.
METHODS FOR RETURNING BRANDING INFORMATION

Use the following techniques to access branding information:

1. Processor brand string method; this method also returns the processor’s maximum operating frequency
2. Processor brand index; this method uses a software supplied brand string table.

These two methods are discussed in the following sections. For methods that are available in early processors, see Section: “Identification of Earlier IA-32 Processors” in Chapter 20 of the Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 1.

The Processor Brand String Method

Figure 1-4 describes the algorithm used for detection of the brand string. Processor brand identification software should execute this algorithm on all Intel 64 and IA-32 processors.

This method (introduced with Pentium 4 processors) returns an ASCII brand identification string and the maximum operating frequency of the processor to the EAX, EBX, ECX, and EDX registers.

How Brand Strings Work

To use the brand string method, execute CPUID with EAX input of 8000002H through 80000004H. For each input value, CPUID returns 16 ASCII characters using EAX, EBX, ECX, and EDX. The returned string will be NULL-terminated.

Table 1-8 shows the brand string that is returned by the first processor in the Pentium 4 processor family.

Extracting the Maximum Processor Frequency from Brand Strings

Figure 1-5 provides an algorithm which software can use to extract the maximum processor operating frequency from the processor brand string.
NOTE
When a frequency is given in a brand string, it is the maximum qualified frequency of the processor, not the frequency at which the processor is currently running.

The Processor Brand Index Method
The brand index method (introduced with Pentium® III Xeon® processors) provides an entry point into a brand identification table that is maintained in memory by system software and is accessible from system- and user-level code. In this table, each brand index is associated with an ASCII brand identification string that identifies the official Intel family and model number of a processor.

When CPUID executes with EAX set to 01H, the processor returns a brand index to the low byte in EBX. Software can then use this index to locate the brand identification string for the processor in the brand identification table. The first entry (brand index 0) in this table is reserved, allowing for backward compatibility with processors that do not support the brand identification feature. Starting with processor signature family ID = 0FH, model = 03H, brand index method is no longer supported. Use brand string method instead.

Table 1-9 shows brand indices that have identification strings associated with them.

**Flags Affected**

None.

**Exceptions (All Operating Modes)**

#UD If the LOCK prefix is used.

In earlier IA-32 processors that do not support the CPUID instruction, execution of the instruction results in an invalid opcode (#UD) exception being generated.§
1.6 COMPRESSED DISPLACEMENT (DISP8*N) SUPPORT IN EVEX

For memory addressing using disp8 form, EVEX-encoded instructions always use a compressed displacement scheme by multiplying disp8 in conjunction with a scaling factor N that is determined based on the vector length, the value of EVEX.b bit (embedded broadcast) and the input element size of the instruction. In general, the factor N corresponds to the number of bytes characterizing the internal memory operation of the input operand (e.g., 64 when accessing a full 512-bit memory vector). The scale factor N is listed in Table 1-10 and Table 1-11 below, where EVEX encoded instructions are classified using the tupletype attribute. The scale factor N of each tupletype is listed based on the vector length (VL) and other factors affecting it.

Table 1-10 covers EVEX-encoded instructions which has a load semantic in conjunction with additional computational or data element movement operation, operating either on the full vector or half vector (due to conversion of numerical precision from a wider format to narrower format). EVEX.b is supported for such instructions for data element sizes which are either dword or qword.

EVEX-encoded instruction that are pure load/store, and “Load+op” instruction semantic that operate on data element size less then dword do not support broadcasting using EVEX.b. These are listed in Table 1-11. Table 1-11 also includes many broadcast instructions which perform broadcast using a subset of data elements without using EVEX.b. These instructions and a few data element size conversion instruction are covered in Table 1-11. Instruction classified in Table 1-11 do not use EVEX.b and EVEX.b must be 0, otherwise #UD will occur.

The tupletype will be referenced in the instruction operand encoding table in the reference page of each instruction, providing the cross reference for the scaling factor N to encoding memory addressing operand.

Note that the disp8*N rules still apply when using 16b addressing.

1.7 BFLOAT16 FLOATING-POINT FORMAT

Intel® Deep Learning Boost (Intel® DL Boost) uses bfloat16 format (BF16). Figure 1-6 illustrates BF16 versus FP16 and FP32.

BF16 has several advantages over FP16:

- It can be seen as a short version of FP32, skipping the least significant 16 bits of mantissa.
- There is no need to support denormals; FP32, and therefore also BF16, offer more than enough range for deep learning training tasks.
- FP32 accumulation after the multiply is essential to achieve sufficient numerical behavior on an application level.
- Hardware exception handling is not needed as this is a performance optimization; industry is designing algorithms around checking inf/NaN.
Instructions described in this document follow the general documentation convention established in the Intel® 64 and IA-32 Architectures Software Developer’s Manual Volume 2A. Additionally, some instructions use notation conventions as described below.

In the instruction encoding, the MODRM byte is represented several ways depending on the role it plays. The MODRM byte has 3 fields: 2-bit MODRM.MOD field, a 3-bit MODRM.REG field and a 3-bit MODRM.RM field. When all bits of the MODRM byte have fixed values for an instruction, the 2-hex nibble value of that byte is presented after the opcode in the encoding boxes on the instruction description pages. When only some fields of the MODRM byte must contain fixed values, those values are specified as follows:

- If only the MODRM.MOD must be 0b11, and MODRM.REG and MODRM.RM fields are unrestricted, this is denoted as 11:rrr:bbb. The rrr correspond to the 3-bits of the MODRM.REG field and the bbb correspond to the 3-bits of the MODRM.RM field.
- If the MODRM.MOD field is constrained to be a value other than 0b11, i.e., it must be one of 0b00, 0b01, or 0b10, then we use the notation !(11).
- If for example only the MODRM.REG field had a specific required value, e.g., 0b101, that would be denoted as mm:101:bbb.

**NOTE**
Historically the Intel® 64 and IA-32 Architectures Software Developer’s Manual only specified the MODRM.REG field restrictions with the notation /0 ... /7 and did not specify restrictions on the MODRM.MOD and MODRM.RM fields in the encoding boxes.

<tbody>
<tr>
<td>A</td>
<td>ModRM:r/m (r, w)</td>
<td>ModRM:reg (r)</td>
<td>N/A</td>
<td>N/A</td>
</tr>
</tbody>
</table>

**Description**

This instruction atomically adds the destination operand (first operand) and the source operand (second operand), and then stores the result in the destination operand.

The destination operand is a memory location and the source operand is a register. In 64-bit mode, the instruction’s default operation size is 32 bits. Using a REX prefix in the form of REX.R permits access to additional registers (R8-R15). Using a REX prefix in the form of REX.W promotes operation to 64 bits. The destination operand must be naturally aligned with respect to the data size, at a 4-byte boundary, or an 8-byte boundary if used with a REX.W prefix in 64-bit mode.

This instruction requires that the destination operand has a write-back (WB) memory type and it is implemented using the weakly-ordered memory consistency model of write combining (WC) memory type. Before the operation, the cache line is written-back (if modified) and invalidated from the processor cache. When the operation completes, the processor may optimize the cacheability of the destination address by writing the result only to specific levels of the cache hierarchy. Because this instruction uses a weakly-ordered memory consistency model, a fencing operation implemented with LFENCE, SFENCE, or MFENCE instruction should be used in conjunction with AADD if a stronger ordering is required. However, note that AADD is not ordered with respect to a younger LFENCE, as this instruction is not loading data from memory into the processor.

Any attempt to execute the AADD instruction inside an Intel TSX transaction will result in a transaction abort.

**Operation**

AADD dest, src

dest := dest + src;

**Flags Affected**

None.

**Protected Mode Exceptions**

- **#GP(0)**: For an illegal memory operand effective address in the CS, DS, ES, FS or GS segments.
  - If the memory address is not naturally aligned to the operand size.
  - If the memory address memory type is not write-back (WB).
- **#SS(0)**: For an illegal address in the SS segment.
- **#PF(fault-code)**: If a page fault occurs.
- **#UD**: If the LOCK prefix is used.
  - If CPUID.(EAX=07H, ECX=01H):EAX.RAO-INT[bit 3] = 0.
Real-Address Mode Exceptions

#GP  If any part of the operand lies outside the effective address space from 0 to FFFFH.
     If the memory address is not naturally aligned to the operand size.
     If the memory address memory type is not write-back (WB).
#SS  For an illegal address in the SS segment.
#UD  If the LOCK prefix is used.
     If CPUID.(EAX=07H, ECX=01H):EAX.RAO-INT[bit 3] = 0.

<td>ModRM:reg (r)</td>
<td>N/A</td>
<td>N/A</td>
</tr>
</tbody>
</table>

Description

This instruction atomically performs a bitwise AND operation of the destination operand (first operand) and the source operand (second operand), and then stores the result in the destination operand.

The destination operand is a memory location and the source operand is a register. In 64-bit mode, the instruction’s default operation size is 32 bits. Using a REX prefix in the form of REX.R permits access to additional registers (R8-R15). Using a REX prefix in the form of REX.W promotes operation to 64 bits. The destination operand must be naturally aligned with respect to the data size, at a 4-byte boundary, or an 8-byte boundary if used with a REX.W prefix in 64-bit mode.

This instruction requires that the destination operand has a write-back (WB) memory type and it is implemented using the weakly-ordered memory consistency model of write combining (WC) memory type. Before the operation, the cache line is written-back (if modified) and invalidated from the processor cache. When the operation completes, the processor may optimize the cacheability of the destination address by writing the result only to specific levels of the cache hierarchy. Because this instructions uses a weakly-ordered memory consistency model, a fencing operation implemented with LFENCE, SFENCE, or MFENCE instruction should be used in conjunction with AAND if a stronger ordering is required. However, note that AAND is not ordered with respect to a younger LFENCE, as this instruction is not loading data from memory into the processor.

Any attempt to execute the AAND instruction inside an Intel TSX transaction will result in a transaction abort.

Operation

AAND dest, src

dest := dest AND src;

Flags Affected

None.

Protected Mode Exceptions

#GP(0) For an illegal memory operand effective address in the CS, DS, ES, FS or GS segments.
If the memory address is not naturally aligned to the operand size.

<td>A</td>
<td>ModRM:r/m (r, w)</td>
<td>ModRM:reg (r)</td>
<td>N/A</td>
<td>N/A</td>
</tr>
</tbody>
</table>

**Description**

This instruction atomically performs a bitwise OR operation of the destination operand (first operand) and the source operand (second operand), and then stores the result in the destination operand.

The destination operand is a memory location and the source operand is a register. In 64-bit mode, the instruction's default operation size is 32 bits. Using a REX prefix in the form of REX.R permits access to additional registers (R8-R15). Using a REX prefix in the form of REX.W promotes operation to 64 bits. The destination operand must be naturally aligned with respect to the data size, at a 4-byte boundary, or an 8-byte boundary if used with a REX.W prefix in 64-bit mode.

This instruction requires that the destination operand has a write-back (WB) memory type and it is implemented using the weakly-ordered memory consistency model of write combining (WC) memory type. Before the operation, the cache line is written-back (if modified) and invalidated from the processor cache. When the operation completes, the processor may optimize the cacheability of the destination address by writing the result only to specific levels of the cache hierarchy. Because this instructions uses a weakly-ordered memory consistency model, a fencing operation implemented with LFENCE, SFENCE, or MFENCE instruction should be used in conjunction with AOR if a stronger ordering is required. However, note that AOR is not ordered with respect to a younger LFENCE, as this instruction is not loading data from memory into the processor.

Any attempt to execute the AOR instruction inside an Intel TSX transaction will result in a transaction abort.

**Operation**

AOR dest, src

dest := dest OR src;

**Flags Affected**

None.

<td>ModRM:r/m (r, w)</td>
<td>ModRM:reg (r)</td>
<td>N/A</td>
<td>N/A</td>
</tr>
</tbody>
</table>

Description

This instruction atomically performs a bitwise XOR operation of the destination operand (first operand) and the source operand (second operand), and then stores the result in the destination operand.

The destination operand is a memory location and the source operand is a register. In 64-bit mode, the instruction’s default operation size is 32 bits. Using a REX prefix in the form of REX.R permits access to additional registers (R8-R15). Using a REX prefix in the form of REX.W promotes operation to 64 bits. The destination operand must be naturally aligned with respect to the data size, at a 4-byte boundary, or an 8-byte boundary if used with a REX.W prefix in 64-bit mode.

This instruction requires that the destination operand has a write-back (WB) memory type and it is implemented using the weakly-ordered memory consistency model of write combining (WC) memory type. Before the operation, the cache line is written-back (if modified) and invalidated from the processor cache. When the operation completes, the processor may optimize the cacheability of the destination address by writing the result only to specific levels of the cache hierarchy. Because this instruction uses a weakly-ordered memory consistency model, a fencing operation implemented with LFENCE, SFENCE, or MFENCE instruction should be used in conjunction with AXOR if a stronger ordering is required. However, note that AXOR is not ordered with respect to a younger LFENCE, as this instruction is not loading data from memory into the processor.

Any attempt to execute the AXOR instruction inside an Intel TSX transaction will result in a transaction abort.

Operation

AXOR dest, src

dest := dest XOR src;

Flags Affected

None.

Protected Mode Exceptions

#GP(0) For an illegal memory operand effective address in the CS, DS, ES, FS or GS segments.
   If the memory address is not naturally aligned to the operand size.
   If the memory address memory type is not write-back (WB).

#SS(0) For an illegal address in the SS segment.

#PF(fault-code) If a page fault occurs.

#UD If the LOCK prefix is used.
   If CPUID.(EAX=07H, ECX=01H):EAX.RAO-INT[bit 3] = 0.
Real-Address Mode Exceptions
#GP If any part of the operand lies outside the effective address space from 0 to FFFFH.
If the memory address is not naturally aligned to the operand size.
If the memory address memory type is not write-back (WB).
#SS For an illegal address in the SS segment.
#UD If the LOCK prefix is used.
If CPUID.(EAX=07H, ECX=01H):EAX.RAO-INT[bit 3] = 0.

Virtual-8086 Mode Exceptions
Same exceptions as in protected mode.

Compatibility Mode Exceptions
Same exceptions as in protected mode.

64-Bit Mode Exceptions
#GP(0) If the memory address is in a non-canonical form.
If the memory address is not naturally aligned to the operand size.
If the memory address memory type is not write-back (WB).
#SS(0) If a memory address referencing the SS segment is in a non-canonical form.
#PF(fault-code) If a page fault occurs.
#UD If the LOCK prefix is used.
If CPUID.(EAX=07H, ECX=01H):EAX.RAO-INT[bit 3] = 0.

</tbody>
</table>
This instruction compares the value from memory with the value of the second operand. If the specified condition is met, then the processor will add the third operand to the memory operand and write it into memory, else the memory is unchanged by this instruction.

This instruction must have MODRM.MOD equal to 0, 1, or 2. The value 3 for MODRM.MOD is reserved and will cause an invalid opcode exception (#UD).

The second operand is always updated with the original value of the memory operand. The EFLAGS conditions are updated from the results of the comparison. The instruction uses an implicit lock. This instruction does not permit the use of an explicit lock prefix.

**Operation**

\[
\text{CMPCCXADD srcdest1, srcdest2, src3} \\
\text{tmp1 := load lock srcdest1} \\
\text{tmp2 := tmp1 + src3} \\
\text{EFLAGS.CS,OF,SF,ZF,AF,PF := CMP tmp1, srcdest2} \\
\text{IF <condition>:} \\
\quad \text{srcdest1 := store unlock tmp2} \\
\text{ELSE} \\
\quad \text{srcdest1 := store unlock tmp1} \\
\text{srcdest2 := tmp1}
\]

**Flags Affected**
The EFLAGS conditions are updated from the results of the comparison.
SIMD Floating-Point Exceptions

None.

#### Description

The PBNDKB instruction allows software to bind information to a platform by encrypting it with a platform-specific wrapping key. The encrypted data may later be used by the PCONFIG instruction to configure the total storage encryption (TSE) engine.\(^1\)

The instruction can be executed only in 64-bit mode. The registers RBX and RCX provide input information to the instruction. Executions of PBNDKB may fail for platform-specific reasons. An execution reports failure by setting the ZF flag and loading EAX with a non-zero failure reason; a successful execution clears ZF and EAX.

The instruction operates on 256-byte data structures called **bind structures**. It reads a bind structure at the linear address in RBX and writes a modified bind structure to the linear address in RCX. The addresses in RBX and RCX must be different from each other and must be 256-byte aligned.

The instruction encrypts a portion of the input bind structure and generates a MAC of parts of that structure. The encrypted data and MAC are written out as part of the output bind structure.

The format of a bind structure is given in Table 2-1.

A description of each of the fields in a bind structure is provided below:

- **MAC**: A MAC produced by PBNDKB of parts of its input bind structure. This field in the input bind structure is not used.
- **IV**: PBNDKB randomly generates a 96-bit initialization vector and uses it as input to an authenticated encryption function. The generated IV is written to the output bind structure. If there is insufficient entropy for the random-number generator, PBNDKB will fail and report the failure by loading EAX with value 1 (ENTROPY_ERROR). This field in the input bind structure is not used.
- **BTENCDATA**: In the input bind structure, the field contains the data to be encrypted. The data consist of two 256-bit keys, a data key and a tweak key. If the value of the KEY_GENERATION_CTRL field of the BTDATA (see below) is 1, PBNDKB randomizes the values of these keys before encrypting them. (If there is insufficient entropy for the random-number generator, PBNDKB will fail and report the failure by loading EAX with value 1 (ENTROPY_ERROR).) PBNDKB writes the encrypted data to this field in the output bind structure.

---

1. For details on Total Storage Encryption (TSE), see Chapter 11 of this document.
• **BTDATA:** This field contains additional control and data that are not encrypted. It has the following format:
  
  — **USER_SUPP_CHALLENGE** (bytes 31:0): PBNDKB uses this value in the input bind structure to determine the wrapping key (see below). It writes zero to this field in the output bind structure.
  
  — **KEY_GENERATION_CTRL** (byte 32): PBNDKB uses this value in the input bind structure to determine whether to randomize the keys being encrypted. The value must be 0 or 1 (otherwise, a #GP occurs).
  
  — The remaining 95 bytes are reserved and must be zero.

PBNDKB determines a 256-bit **wrapping key** by computing an HMAC based on SHA-256 using 256-bit platform-specific key and the USER_SUPP_CHALLENGE in the BTDATA field in the input bind structure.

PBNDKB then uses the wrapping key and an AES GCM authenticated encryption function to encrypt BTENCDATA and produce a MAC. The encryption function uses the following inputs:

• The 64-byte BTENCDATA to be encrypted (which may have been randomized; see above).
• The 256-bit wrapping key.
• The 96-bit IV randomly generated by PBNDKB.
• 176 bytes of additional authenticated data that are the concatenation of 8 bytes of zeroes, the IV, 28 bytes of zeroes, and the BTDATA in the input bind structure.
• The length of the additional authenticated data (176).

The encryption function produces a structure with 64 bytes of encrypted data and a 16-byte MAC. PBNDKB saves these values to the corresponding fields in its output bind structure. Other fields are copied from the input bind structure or written as zero, except the IV (which receives the randomly generated value) and the USER_SUPP_CHALLENGE in the BTDATA, which is written as zero.

**Operation**

Protected Mode Exceptions
#UD PBNDKB is not supported in protected mode.

Real-Address Mode Exceptions
#UD PBNDKB is not supported in real-address mode.
Virtual-8086 Mode Exceptions

#UD PBNDKB is not supported in virtual-8086 mode.

Compatibility Mode Exceptions

Same exceptions as in protected mode.

64-Bit Mode Exceptions

#GP(0) If the values of RBX and RCX are not both canonical.
If RBX or RCX is not 256B aligned.
If RBX = RCX.
If any of the reserved bytes in the input bind structure are set (including bytes in BTDATA).
If the value of the key-generation control in the BTDATA field of the input bind structure is not 0 or 1.

#PF(fault-code) If a page fault occurs in accessing memory operands.

#UD If any of the LOCK/REP/Operand Size/VEX prefixes are used.
If the current privilege level is not 0.
If CPUID.(EAX=07H, ECX=01H):EBX.TSE[bit 1] = 0.

**Description**

The PCONFIG instruction allows software to configure certain platform features. It supports these features with multiple leaf functions, selecting a leaf function using the value in EAX.

Depending on the leaf function, the registers RBX, RCX, and RDX may be used to provide input information or for the instruction to report output information. Addresses and operands are 32 bits outside 64-bit mode and are 64 bits in 64-bit mode. The value of CS:D does not affect operand size or address size.

Executions of PCONFIG may fail for platform-specific reasons. An execution reports failure by setting the ZF flag and loading EAX with a non-zero failure reason; a successful execution clears ZF and EAX.

Each PCONFIG leaf function applies to a specific hardware block called a PCONFIG target. The leaf function is supported only if the processor supports that target. Each target is associated with a numerical target identifier, and CPUID leaf 1BH (PCONFIG information) enumerates the identifiers of the supported targets. An attempt to execute an undefined leaf function, or a leaf function that applies to an unsupported target identifier, results in a general-protection exception (#GP).

**Leaf Function MKTME_KEY_PROGRAM**

PCONFIG leaf function 0 (selected by loading EAX with value 0) is used for key programming for total memory encryption-multi-key (TME-MK). This leaf function is called MKTME_KEY_PROGRAM and it pertains to the TME-MK target, which has target identifier 1. The leaf function uses the EBX (or RBX) register for additional input information.

Software uses this leaf function to manage the encryption key associated with a particular key identifier (KeyID).

The leaf function uses a data structure called the TME-MK key programming structure (MKTME_KEY_PROGRAM_STRUCT). Software provides the address of the structure (as an offset in the DS segment) in EBX (or RBX). The format of the structure is given in Table 2-2.

1. Further details on TME-MK can be found here: [https://software.intel.com/sites/default/files/managed/a5/16/Multi-Key-Total-Memory-Encryption-Spec.pdf](https://software.intel.com/sites/default/files/managed/a5/16/Multi-Key-Total-Memory-Encryption-Spec.pdf)
A description of each of the fields in MKTME_KEY_PROGRAM_STRUCT is provided below:

- **KEYID**: The key identifier (KeyID) being programmed to the MKTME engine. The leaf function causes a general-protection exception (#GP) if the KeyID is zero. KeyID zero always uses the current behavior configured for TME (total memory encryption), either to encrypt with platform TME key or to bypass TME encryption. The leaf function also causes a #GP if the KeyID exceeds the maximum enumerated in IA32_TME_CAPACITY.MK_TME_MAX_KEYS[bits 50:36] or configured by the setting of IA32_TME_ACTIVATE.MK_TME_KEYID_BITS[bits 35:32].

- **KEYID_CTRL**: The KEYID_CTRL field comprises two sub-fields used by software to control the encryption performed for the selected KeyID:
  
  - Key-programming command (COMMAND; bits 7:0). This 8-bit field should contain one of the following values:
    
    - **KEYID_SET_KEY_DIRECT** (value 0). With this command, software programs directly the encryption key to be used for the selected KeyID.
    
    - **KEYID_SET_KEY_RANDOM** (value 1). With this command, software has the CPU generate and assign an encryption key to be used for the selected KeyID using a hardware random-number generator.
      
      If this command is used and there is insufficient entropy for the random-number generator, the leaf function will fail and report the failure by loading EAX with value 2 (ENTROPY_ERROR).
      
      Because the keys programmed by this leaf function are discarded on reset and software cannot read the programmed keys, the keys programmed with this command are ephemeral.
    
    - **KEYID_CLEAR_KEY** (value 2). With this command, software indicates that the selected KeyID should use the current behavior configured for TME (see above).
    
    - **KEYID_NO_ENCRYPT** (value 3). With this command, software indicates that no encryption should be used for the selected KeyID.

  If any other value is used, the leaf function causes a #GP.

  - Encryption algorithm (ENC_ALG, bits 23:8). Bits 63:48 of the IA32_TME_ACTIVATE MSR (MSR index 982H) indicate which encryption algorithms are supported by the platform. The 16-bit ENC_ALG field should specify one of the algorithms indicated in IA32_TME_ACTIVATE. The leaf function causes a #GP if ENC_ALG does not set exactly one bit or if it sets a bit whose corresponding bit is not set in IA32_TME_ACTIVATE[63:48].

- **KEY_FIELD_1**: Use of this field depends upon selected key-programming command:
  
  - If the direct key-programming command is used (KEYID_SET_KEY_DIRECT), this field carries the software-supplied data key to be used for the KeyID.
  
  - If the random key-programming command is used (KEYID_SET_KEY_RANDOM), this field carries the software-supplied entropy to be mixed in the CPU generated random data key.
  
  - This field is ignored when one of the other key-programming commands is used.

  It is software’s responsibility to ensure that the key supplied for the direct key-programming option or the entropy supplied for the random key-programming option does not result in weak keys. There are no explicit checks in the instruction to detect or prevent weak keys.

- **KEY_FIELD_2**: Use of this field depends upon selected key-programming command:
  
  - If the direct key-programming command is used (KEYID_SET_KEY_DIRECT), this field carries the software-supplied tweak key to be used for the KeyID.
  
  - If the random key-programming command is used (KEYID_SET_KEY_RANDOM), this field carries the software-supplied entropy to be mixed in the CPU generated random tweak key.
  
  - This field is ignored when one of the other key-programming commands is used.

  It is software’s responsibility to ensure that the key supplied for the direct key-programming option or the entropy supplied for the random key-programming option does not result in weak keys. There are no explicit checks in the instruction to detect or prevent weak keys.

All KeyIDs default to TME behavior (encrypt with TME key or bypass encryption) on activation of TME-MK. Software can at any point decide to change the key for a KeyID using this leaf function. Changing the key for a KeyID does
not change the state of the TLB caches or memory pipeline. Software is responsible for taking appropriate actions to ensure correct behavior.

The key table used by TME-MK is shared by all logical processors in a platform. For this reason, execution of this leaf function must gain exclusive access to the key table before updating it. The leaf function does this by acquiring a lock (implemented in the platform) and retaining that lock until the execution completes. An execution of the leaf function may fail to acquire the lock if it is already in use. In this situation, the leaf function will load EAX with failure reason 5 (DEVICE_BUSY). When this happens, the key table is not updated, and software should retry execution of PCONFIG.

**Leaf Function TSE_KEY_PROGRAM**

PCONFIG leaf function 1 (selected by loading EAX with value 1) is used for direct key programming for total storage encryption (TSE). This leaf function is called TSE_KEY_PROGRAM and it pertains to the TSE target, which has target identifier 2. The leaf function can be used only in 64-bit mode. It uses the RBX register for additional input information.

Software uses this leaf function to manage the encryption key associated with a particular key identifier (KeyID). The leaf function uses a data structure called the TSE key programming structure (TSE_KEY_PROGRAM_STRUCT). Software provides the linear address of the structure in RBX. The format of the structure is given in Table 2-3.

A description of each of the fields in MKTME_KEY_PROGRAM_STRUCT is provided below:

- **KEYID**: The key identifier (KeyID) being programmed to the TSE engine. The leaf function causes a general-protection exception (#GP) if the KeyID exceeds the maximum enumerated in the TSE_MAX_KEYS field (bits 50:36) of the IA32_TSE_CAPABILITY MSR (MSR index 9F1H).

- **KEYID_CTRL**: The KEYID_CTRL field comprises two sub-fields used by software to control the encryption performed for the selected KeyID:
  - Key-programming command (COMMAND; bits 7:0). This 8-bit field should contain one of the following values:
    - TSE_SET_KEY_DIRECT (value 0). With this command, software programs directly the encryption key to be used for the selected KeyID.
    - TSE_NO_ENCRYPT (value 1). With this command, software indicates that no encryption should be used for the selected KeyID.
  
  If any other value is used, the leaf function causes a #GP.

  - Encryption algorithm (ENC_ALG, bits 23:8). IA32_TSE_CAPABILITY[15:0] indicates which encryption algorithms are supported by the platform. The 16-bit ENC_ALG field should specify one of the algorithms indicated in IA32_TSE_CAPABILITY. The leaf function causes a #GP if ENC_ALG does not set exactly one bit or if it sets a bit whose corresponding bit is not set in IA32_TSE_CAPABILITY.

- **KEY_FIELD_1**: If the direct key-programming command is used (TSE_SET_KEY_DIRECT), this field carries the software supplied data key to be used for the KeyID. Otherwise, the field is ignored.
KEY_FIELD_2: If the direct key-programming command is used (TSE_SET_KEY_DIRECT), this field carries the software supplied tweak key to be used for the KeyID. Otherwise, the field is ignored.

The TSE key table is shared by all logical processors in a platform. For this reason, execution of this leaf function must gain exclusive access to the key table before updating it. The leaf function does this by acquiring a lock (implemented in the platform) and retaining that lock until the execution completes. An execution of the leaf function may fail to acquire the lock if it is already in use. In this situation, the leaf function will load EAX with failure reason 5 (DEVICE_BUSY). When this happens, the key table is not updated, and software should retry execution of PCONFIG.

Leaf Function TSE_KEY_PROGRAM_WRAPPED

PCONFIG leaf function 2 (selected by loading EAX with value 2) is used for wrapped key programming for total storage encryption (TSE). This leaf function is called TSE_KEY_PROGRAM_WRAPPED and it pertains to the TSE target, which has target identifier 2. The leaf function can be used only in 64-bit mode. It uses the RBX and RCX registers for additional input information.

Software uses this leaf function to manage the encryption key associated with a particular key identifier (KeyID). The leaf function uses control input provided in RBX. The format of that input is given in Table 2-4.

<table>
<thead>
<tr>
<th>Field</th>
<th>Bit Positions</th>
<th>Comments</th>

<td>63:40</td>
<td>Not used.</td>
</tr>
</tbody>
</table>

A description of each of the fields in the control input is provided below:

- **KEYID**: The key identifier (KeyID) being programmed to the TSE engine. The leaf function causes a general-protection exception (#GP) if the KeyID exceeds the maximum enumerated in the TSE_MAX_KEYs field (bits 50:36) of the IA32_TSE_CAPABILITY MSR (MSR index 9F1H).

- **ENC_ALG**: The encryption algorithm selected for the KeyID. IA32_TSE_CAPABILITY[15:0] indicates which encryption algorithms are supported by the platform. The 16-bit ENC_ALG field should specify one of the algorithms indicated in IA32_TSE_CAPABILITY. The leaf function causes a #GP if ENC_ALG does not set exactly one bit or if it sets a bit whose corresponding bit is not set in IA32_TSE_CAPABILITY.

The leaf function also uses a 256-byte data structure called the **bind structure**. This structure should be the output of the PBNDKB instruction, subsequently modified by software (see below). Software provides the linear address of the structure in RCX. The format of the structure is given in Table 2-5.

<table>
<thead>
<tr>

</tr>
<tr>
<td>BTDATA</td>
<td>128</td>
<td>128</td>
<td>Additional control and data (not encrypted)</td>
</tr>
</tbody>
</table>

A description of each of the fields in TSE_BIND_STRUCT is provided below:

- **MAC**: A MAC produced by PBNDKB of its input bind structure. The PCONFIG leaf function will recompute the MAC and confirm that it matches this value.
- **IV**: The initialization vector that PBNDKB used for encryption. The PCONFIG leaf function will use this in its decryption of encrypted data and computation of the MAC.
- **BTENCDATA**: Data which had been encrypted by PBNDKB, containing the data and tweak keys to be used by TSE.
- **BTDATA**: Data that was input to PBNDKB that was output without encryption. It has the following format:
  - **USER_SUPP_CHALLENGE** (bytes 31:0): PBNDKB uses a value provided by software in its input bind structure but writes zero to this field in the output bind structure to be used by PCONFIG. Software should configure this field with the proper value before executing this PCONFIG leaf function.
  - **KEY_GENERATION_CTRL** (byte 32): PBNDKB uses this value to determine whether to generate random keys. The PCONFIG leaf function does not use this field.
  - The remaining 95 bytes are reserved and must be zero.

The leaf function determines a 256-bit **wrapping key** by computing an HMAC based on SHA-256 using 256-bit platform-specific key and the USER_SUPP_CHALLENGE in the BTDATA field of the TSE_BIND_STRUCT.

Using the wrapping key, the leaf function uses an AES GCM authenticated decryption function to decrypt BTENCDATA and compute a MAC. The decryption function uses the following inputs:
- The 64-byte BTENCDATA from TSE_BIND_STRUCT to be decrypted.
- The 256-bit wrapping key.
- The 96-bit IV from TSE_BIND_STRUCT.
- Additional authenticated data that is the concatenation of bytes 63:16 and bytes 255:128 of the TSE_BIND_STRUCT. These 176 bytes will comprise 8 bytes of zeroes, the 12-byte IV, 28 bytes of zeroes, and 128 bytes of BTDATA of which the upper 95 bytes are zero.
- The length of the additional authenticated data (176).

The decryption function produces a structure with a 64 bytes of decrypted data and a 16-byte MAC. The decrypted data comprises a 256-bit data key and a 256-bit tweak key.

If the MAC produced by the decryption function differs from that provided in the TSE_BIND_STRUCT, the leaf function will load EAX with failure reason 7 (UNWRAP_FAILURE). Otherwise, the leaf function will attempt to program the TSE key table for the selected KeyID with the keys contained in the decrypted data.

The TSE key table is shared by all logical processors in a platform. For this reason, execution of this leaf function must gain exclusive access to the key table before updating it. The leaf function does this by acquiring a lock (implemented in the platform) and retaining that lock until the execution completes. An execution of the leaf function may fail to acquire the lock if it is already in use. In this situation, the leaf function will load EAX with failure reason 5 (DEVICE_BUSY). When this happens, the key table is not updated, and software should retry execution of PCONFIG.

</thead>
<tbody>
<tr>
<td>ZO</td>
<td>N/A</td>
<td>N/A</td>
<td>N/A</td>
<td>N/A</td>
</tr>
</tbody>
</table>

Description

This instruction reads a software-provided list of up to 64 MSRs and stores their values in memory.

RDMSRLIST takes three implied input operands:

- **RSI**: Linear address of a table of MSR addresses (8 bytes per address).
- **RDI**: Linear address of a table into which MSR data is stored (8 bytes per MSR).
- **RCX**: 64-bit bitmask of valid bits for the MSRs. Bit 0 is the valid bit for entry 0 in each table, etc.

For each RCX bit \([n]\) from 0 to 63, if RCX\([n]\) is 1, RDMSRLIST will read the MSR specified at entry \([n]\) in the RSI table and write it out to memory at the entry \([n]\) in the RDI table. This implies a maximum of 64 MSRs that can be processed by this instruction. The processor will clear RCX\([n]\) after it finishes handling that MSR. Similar to repeated string operations, RDMSRLIST supports partial completion for interrupts, exceptions, and traps. In these situations, the RIP register saved will point to the RDMSRLIST instruction while the RCX register will have cleared bits corresponding to all completed iterations.

This instruction must be executed at privilege level 0; otherwise, a general protection exception \#GP(0) is generated. This instruction performs MSR specific checks and respects the VMX MSR VM-execution controls in the same manner as RDMSR.

Although RDMSRLIST accesses the entries in the two tables in order, the actual reads of the MSRs may be performed out of order: for table entries \(m < n\), the processor may read the MSR for entry \(n\) before reading the MSR for entry \(m\). (This may be true also for a sequence of executions of RDMSR.) Ordering is guaranteed if the address of the IA32_BARRIER MSR (2FH) appears in the table of MSR addresses. Specifically, if IA32_BARRIER appears at entry \(m\), then the MSR read for any entry \(n\) with \(n > m\) will not occur until (1) all instructions prior to RDMSRLIST have completed locally; and (2) MSRs have been read for all table entries before entry \(m\).

The processor is allowed to (but not required to) “load ahead” in the list. Examples:

- Use old memory type or TLB translation for loads/stores to list memory despite an MSR written by a previous iteration changing MTRR or invalidating TLBs.
- Cause a page fault or EPT violation for a memory access to an entry > “n” in MSR address or data tables, despite the processor only having read or written “n” MSRs.\(^1\)

Virtualization Behavior—VM Exit Causes

Like RDMSR, the RDMSRLIST instruction executed in VMX non-root operation causes a VM exit if any of the following are true:

- The “use MSR bitmaps” VM-execution control is 0.
- The value of MSR address is not in the ranges 00000000H–00001FFFH and C0000000H–C0001FFFH.
- The value of MSR address is in the range 00000000H–00001FFFH and bit \(n\) in read bitmap for low MSRs is 1, where \(n\) is the value of the MSR address.

---

1. For example, the processor may take a page fault due to a linear address for the 10th entry in the MSR address table despite only having completed the MSR writes up to entry 5.
The value of ECX is in the range C0000000H–C0001FFFH and bit n in read bitmap for high MSRs is 1, where n is the value of the MSR address & 00001FFFH.

A VM exit for the above reasons for the RDMSRLIST instruction will specify exit reason 78 (decimal). The exit qualification is set to the MSR address causing the VM exit if “use MSR bitmaps” VM-execution control is 1. If “use MSR bitmaps” VM-execution control is 0, then the VM-exit qualification will be 0.

If software wants to emulate a single iteration of RDMSRLIST after a VM exit, it can use the exit qualification to identify the MSR. Such software will need to write to the table of data. It can calculate the guest-linear address of the table entry to write by using the values of RDI (the guest-linear address of the table) and RCX (the lowest bit set in RCX identifies the specific table entry.

Virtualization Behavior—Changed Behavior in Non-Root Operation

The previous section identifies when executions of the RDMSRLIST instruction cause VM exits. Under the following situations, a #UD will occur instead of a VM exit or a fault due to CPL 0:

• The “Enable MSRLIST Instructions” VM-execution control is 0.
• The “Activate tertiary controls” VM-execution control is 0.

If that does not occur and there is no fault due to CPL > 0 nor a VM exit, the instruction’s behavior may be modified for certain values of MSR address in the same manner as RDMSR for a read of the same MSR.

Operation

```c
WHILE (RCX != 0) {
    MSR_index = TZCNT(RCX)
    MSR_address = mem[RSI + (MSR_index * 8)]
    VM exit if specified by VM-execution controls (for specified MSR_address)
    #GP(0) if MSR_address[61:32] !=0
    #GP(0) if MSR_address is not accessible for RDMSR
    mem[RDI + (MSR_index * 8)] = RDMSR (MSR_address)
    Clear RCX [MSR_index]
    Take any pending interrupts/traps
}
```

Flags Affected

None.

Protected Mode Exceptions

#UD The RDMSRLIST instruction is not recognized in protected mode.

Real-Address Mode Exceptions

#UD The RDMSRLIST instruction is not recognized in real-address mode.

Virtual-8086 Mode Exceptions

#UD The RDMSRLIST instruction is not recognized in virtual-8086 mode.

Compatibility Mode Exceptions

#UD The RDMSRLIST instruction is not recognized in compatibility mode.
64-Bit Mode Exceptions

#GP(0) If the current privilege level is not 0.
     If RSI [2:0] ≠ 0 OR RDI [2:0] ≠ 0.
     If an execution of RDMSR from a specified MSR would generate a general protection exception #GP(0).

#UD If the LOCK prefix is used.
     If not in 64-bit mode.
     If CPUID.(EAX=07H, ECX=01H):EAX.MSRLIST[bit 27] = 0.

**Description**

This instruction loads packed FP32 elements from a SIMD register or memory, converts the elements to BF16, and writes the result to the destination SIMD register.

The upper bits of the destination register beyond the down-converted BF16 elements are zeroed.

This instruction uses "Round to nearest (even)" rounding mode. Output denormals are always flushed to zero and input denormals are always treated as zero. MXCSR is not consulted nor updated.

**Operation**

```plaintext
define convert_fp32_to_bfloat16(x):
    IF x is zero or denormal:
        dest[15] := x[31] // sign preserving zero (denormal go to zero)
        dest[14:0] := 0
    ELSE IF x is infinity:
        dest[15:0] := x[31:16]
    ELSE IF x is nan:
        dest[15:0] := x[31:16] // truncate and set msb of the mantisa force qnan
        dest[6] := 1
    ELSE // normal number
        lsb := x[16]
        rounding_bias := 0x00007FFF + lsb
        temp[31:0] := x[31:0] + rounding_bias // integer add
        dest[15:0] := temp[31:16]
    return dest
```

Description

Multiplies the individual bytes of the first source operand by the corresponding bytes of the second source operand, producing intermediate word results. The word results are then summed and accumulated in the destination dword element size operand.

For unsigned saturation, when an individual result value is beyond the range of an unsigned doubleword (that is, greater than FFFF_FFFFH), the saturated unsigned doubleword integer value of FFFF_FFFFH is stored in the doubleword destination.

For signed saturation, when an individual result is beyond the range of a signed doubleword integer (that is, greater than 7FFF_FFFFH or less than 8000_0000H), the saturated value of 7FFF_FFFFH or 8000_0000H, respectively, is written to the destination operand.

### Description

The VSHA512MSG1 instruction is one of the two SHA512 message scheduling instructions. The instruction performs an intermediate calculation for the next four SHA512 message qwords.

### Operation

Define `ROR64(qword, n):
```
count := n % 64
dest := (qword >> count) | (qword << (64-count))
return dest
```

Define `SHR64(qword, n):
```
return qword >> n
```

Define `s0(qword):
```
return ROR64(qword,1) ^ ROR64(qword, 8) ^ SHR64(qword, 7)
```

### VSHA512MSG1 SRCDEST, SRC1

Define `W[4] := SRC1.qword[0]`

Define `W[0] := SRCDEST.qword[0]`

Define `SRCDEST.qword[0] := W[0] + s0(W[1])`

### Flags Affected

None.

### SIMD Floating-Point Exceptions

Description

The VSM3RNDS2 instruction performs two rounds of SM3 operation using initial SM3 state (C, D, G, H) from the first operand, an initial SM3 states (A, B, E, F) from the second operand and a pre-computed words from the third operand. The first operand with initial SM3 state of (C, D, G, H) assumes input of non-rotated left variables from previous state. The updated SM3 state (A, B, E, F) is written to the first operand.

The imm8 should contain the even round number for the first of the two rounds computed by this instruction. The computation masks the imm8 value by AND’ing it with 0x3E so that only even round numbers from 0 through 62 are used for this operation.

Operation

**Description**

The VSM4KEY4 instruction performs four rounds of SM4 key expansion. The instruction operates on independent 128-bit lanes.

Additional details can be found at: [https://tools.ietf.org/html/draft-ribose-cfrg-sm4-10](https://tools.ietf.org/html/draft-ribose-cfrg-sm4-10).

Both SM4 instructions use a common sbox table:

```plaintext
BYTE sbox[256] = {
0xD6, 0x90, 0xE9, 0xFE, 0xCC, 0xE1, 0x3D, 0xB7, 0x16, 0xB6, 0x14, 0xC2, 0x28, 0xFB, 0x2C, 0x05, 0x2B, 0x67, 0x9A, 0xE9, 0x76, 0x2A, 0xB7, 0x04, 0xC3, 0xAA, 0x44, 0x13, 0x26, 0x49, 0x86, 0x60, 0x99, 0x9C, 0x42, 0x50, 0xF4, 0x91, 0xEF, 0x98, 0x76, 0x23, 0x54, 0x0B, 0x43, 0x86, 0x95, 0x80, 0xDF, 0x94, 0x8F, 0x3F, 0xA6, 0x47, 0x07, 0xA7, 0x6F, 0xF3, 0x73, 0x17, 0x8A, 0x83, 0x59, 0x3C, 0x19, 0x66, 0xB5, 0x4F, 0xA8, 0x68, 0x6B, 0x81, 0xB2, 0x71, 0x64, 0xDA, 0x8B, 0x8F, 0xE8, 0x0F, 0x4B, 0x70, 0x56, 0x9D, 0x35, 0x1E, 0x24, 0x0E, 0x5E, 0x63, 0x58, 0xD1, 0xA2, 0x25, 0x22, 0x7C, 0x3B, 0x01, 0x21, 0x78, 0x87, 0xD4, 0x00, 0x46, 0x57, 0x9F, 0xD3, 0x27, 0x52, 0x4C, 0x36, 0x02, 0xE7, 0xA0, 0xC4, 0xCB, 0x9E, 0xEA, 0xBF, 0x8A, 0xD2, 0x40, 0xC7, 0x3B, 0xB5, 0xA3, 0xF7, 0xF2, 0xCE, 0xF9, 0x61, 0x15, 0xA1, 0xE0, 0xAE, 0x5D, 0xA4, 0x9B, 0x34, 0x1A, 0x55, 0xAD, 0x93, 0x32, 0x30, 0xF5, 0x8C, 0xB1, 0xE3, 0x10, 0xD6, 0xE2, 0x82, 0x66, 0xCA, 0x60, 0xC0, 0x29, 0x23, 0xAB, 0xD0, 0x53, 0x4E, 0x6F, 0xD5, 0xDB, 0x37, 0x45, 0xDE, 0xFD, 0x0F, 0x03, 0xFF, 0x6A, 0x72, 0x6D, 0x6C, 0x5B, 0x51, 0x8D, 0x1B, 0x8F, 0x92, 0xBD, 0x0D, 0x8C, 0x7F, 0x11, 0xD9, 0x5C, 0x41, 0x1F, 0x10, 0x5A, 0x08, 0x0A, 0xC1, 0x31, 0x88, 0xA5, 0xCD, 0xB7, 0xBD, 0x2D, 0x74, 0xD0, 0x12, 0xBB, 0xE5, 0x84, 0x8B, 0x99, 0x69, 0x97, 0x4A, 0x0C, 0x96, 0x77, 0x7C, 0x65, 0xB9, 0xF1, 0x09, 0xC5, 0x6E, 0xCB, 0x84, 0x18, 0xF0, 0x7D, 0xEC, 0x3A, 0xDC, 0x4D, 0x20, 0x79, 0xEE, 0x5F, 0x3E, 0xD7, 0xCB, 0x39, 0x4F

Description

This instruction writes a software provided list of up to 64 MSRs with values loaded from memory.

WRMSRLIST takes three implied input operands:

- **RSI**: Linear address of a table of MSR addresses (8 bytes per address).
- **RDI**: Linear address of a table from which MSR data is loaded (8 bytes per MSR).
- **RCX**: 64-bit bitmask of valid bits for the MSRs. Bit 0 is the valid bit for entry 0 in each table, etc.

For each RCX bit \([n]\) from 0 to 63, if \(\text{RCX}[n]\) is 1, WRMSRLIST will write the MSR specified at entry \([n]\) in the RSI table with the value read from memory at the entry \([n]\) in the RDI table.

This implies a maximum of 64 MSRs that can be processed by this instruction. The processor will clear RCX\([n]\) after it finishes handling that MSR. Similar to repeated string operations, WRMSRLIST supports partial completion for interrupts, exceptions, and traps. In these situations, the RIP register saved will point to the MSRLIST instruction while the RCX register will have cleared bits corresponding to all completed iterations.

This instruction must be executed at privilege level 0; otherwise, a general protection exception \#GP(0) is generated. This instruction performs MSR specific checks and respects the VMX MSR VM-execution controls in the same manner as WRMSR.

Like WRMSRNS (and unlike WRMSR), WRMSRLIST is not defined as a serializing instruction (see “Serializing Instructions” in Chapter 9 of the Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A). This means that software should not rely on WRMSRLIST to drain all buffered writes to memory before the next instruction is fetched and executed. For implementation reasons, some processors may serialize when writing certain MSRs, even though that is not guaranteed.

Like WRMSR and WRMSRNS, WRMSRLIST will ensure that all operations before the WRMSRLIST do not use the new MSR value and that all operations after the WRMSRLIST do use the new value. An exception to this rule is certain store-related performance monitor events that only count when those stores are drained to memory. Since WRMSRLIST is not a serializing instruction, if software is using WRMSRLIST to change the controls for such performance monitor events, then stores before the WRMSRLIST may be counted with new MSR values written by WRMSRLIST. Software can insert the SERIALIZE instruction before the WRMSRLIST if so desired.

Those MSRs that cause a TLB invalidation when they are written via WRMSR (e.g., MTRRs) will also cause the same TLB invalidation when written by WRMSRLIST.

In places where WRMSR is being used as a proxy for a serializing instruction, a different serializing instruction can be used (e.g., SERIALIZE).

WRMSRLIST writes MSRs in order, which means the processor will ensure that an MSR in iteration "n" will be written only after previous iterations ("n-1"). If the older MSR writes had a side effect that affects the behavior of the next MSR, the processor will ensure that side effect is honored.

The processor is allowed to (but not required) "load ahead" in the list. Examples:

- Use old memory type or TLB translation for loads from list memory despite an MSR written by a previous iteration changing MTRR or invalidating TLBs.
- Cause a page fault or EPT violation for a memory access to an entry \(> "n"\) in MSR address or data tables, despite the processor only having read or written \("n"\) MSRs.\(^1\)
**Virtualization Behavior—VM Exit Causes**

Like WRMSR, the WRMSRLIST instruction executed in VMX non-root operation causes a VM exit if any of the following are true:

- The "use MSR bitmaps" VM-execution control is 0.
- The value of MSR address is not in the ranges 00000000H–00001FFFH and C0000000H–C0001FFFH.
- The value of MSR address is in the range 00000000H–00001FFFH and bit n in read bitmap for low MSRs is 1, where n is the value of the MSR address.
- The value of ECX is in the range C0000000H–C0001FFFH and bit n in read bitmap for high MSRs is 1, where n is the value of the MSR address & 00001FFFH.

A VM exit for the above reasons for the WRMSRLIST instruction will specify exit reason 79 (decimal). The exit qualification is set to the MSR address causing the VM exit if "use MSR bitmaps" VM-execution control is 1. If "use MSR bitmaps" VM-execution control is 0, then the VM-exit qualification will be 0.

If software wants to emulate a single iteration of WRMSRLIST after a VM exit, it can use the exit qualification to identify the MSR. Such software will need to read from the table of data. It can calculate the guest-linear address of the table entry to read by using the values of RDI (the guest-linear address of the table) and RCX (the lowest bit set in RCX identifies the specific table entry).

**Virtualization Behavior—Changed Behavior in Non-Root Operation**

The previous section identifies when executions of the WRMSRLIST instruction cause VM exits. Under the following situations, a #UD will occur instead of a VM exit or a fault due to CPL 0:

- The "Enable MSRLIST Instructions" VM-execution control is 0.
- The "Activate tertiary controls" VM-execution control is 0.

If that does not occur and there is no fault due to CPL > 0 nor a VM exit, the instruction’s behavior may be modified for certain values of MSR address in the same manner as WRMSR for a read of the same MSR.

**Operation**

```c
WHILE (RCX != 0) {
    MSR_index = TZCNT(RCX)
    MSR_address = mem[RSI + (MSR_index * 8)]
    MSR_data = mem[RDI + (MSR_index * 8)]
    VM exit if specified by VM-execution controls (for specified MSR_address)
    #GP(0) if MSR_address[61:32] != 0
    #GP(0) if MSR_address is not accessible for WRMSR
    #GP(0) if MSR_data has reserved bits set for MSR
    #GP(0) for any other MSR_address specific checks
    WRMSRNS (MSR_address) = MSR_data
    Clear RCX [MSR_index]
    Take any pending interrupts/traps
}
```

**Flags Affected**

None.

---

1. For example, the processor may take a page fault due to a linear address for the 10th entry in the MSR address table despite only having completed the MSR writes up to entry 5.
Protected Mode Exceptions
#UD The WRMSRLIST instruction is not recognized in protected mode.

Real-Address Mode Exceptions
#UD The WRMSRLIST instruction is not recognized in real-address mode.

Virtual-8086 Mode Exceptions
#UD The WRMSRLIST instruction is not recognized in virtual-8086 mode.

Compatibility Mode Exceptions
#UD The WRMSRLIST instruction is not recognized in compatibility mode.

64-Bit Mode Exceptions
#GP(0) If the current privilege level is not 0.
If RSI [2:0] ≠ 0 OR RDI [2:0] ≠ 0.
If an execution of WRMSR to a specified MSR with a specified value would generate a general-protection exception (#GP(0)).

#UD If the LOCK prefix is used.
If not in 64-bit mode.
If CPUID.(EAX=07H, ECX=01H):EAX.MSRLIST[bit 27] = 0.

### Description

WRMSRNS is an instruction that behaves exactly like WRMSR, with the only difference being that it is not a serializing instruction by default.

Writes the contents of registers EDX:EAX into the 64-bit model specific register (MSR) specified in the ECX register. The contents of the EDX register are copied to the high-order 32 bits of the selected MSR and the contents of the EAX register are copied to the low-order 32 bits of the MSR. The high-order 32 bits of RAX, RCX, and RDX are ignored.

This instruction must be executed at privilege level 0 or in real-address mode; otherwise, a general protection exception #GP(0) is generated.

Unlike WRMSR, WRMSRNS is not defined as a serializing instruction (see “Serializing Instructions” in Chapter 9 of the Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A). This means that software should not rely on it to drain all buffered writes to memory before the next instruction is fetched and executed. For implementation reasons, some processors may serialize when writing certain MSRs, even though that is not guaranteed.

Like WRMSR, WRMSRNS will ensure that all operations before it do not use the new MSR value and that all operations after the WRMSRNS do use the new value. An exception to this rule is certain store related performance monitor events that only count when those stores are drained to memory. Since WRMSRNS is not a serializing instruction, if software is using WRMSRNS to change the controls for such performance monitor events, then stores before the WRMSRNS may be counted with new MSR values written by WRMSRNS. Software can insert the SERIALIZE instruction before the WRMSRNS if so desired.

Those MSRs that cause a TLB invalidation when they are written via WRMSR (e.g., MTRRs) will also cause the same TLB invalidation when written by WRMSRNS. In order to improve performance, software may replace WRMSR with WRMSRNS. In places where WRMSR is being used as a proxy for a serializing instruction, a different serializing instruction can be used (e.g., SERIALIZE).

### Operation

MSR[ECX] := EDX:EAX;

### Flags Affected

None.
3.1 INTRODUCTION

Intel® Advanced Matrix Extensions (Intel® AMX) is a new 64-bit programming paradigm consisting of two components: a set of 2-dimensional registers (tiles) representing sub-arrays from a larger 2-dimensional memory image, and an accelerator able to operate on tiles, the first implementation is called TMUL (tile matrix multiply unit).

An Intel AMX implementation enumerates to the programmer how the tiles can be programmed by providing a palette of options. Two palettes are supported; palette 0 represents the initialized state, and palette 1 consists of 8 KB of storage spread across 8 tile registers named TMM0..TMM7. Each tile has a maximum size of 16 rows x 64 bytes, (1 KB), however the programmer can configure each tile to smaller dimensions appropriate to their algorithm. The tile dimensions supplied by the programmer (rows and bytes_per_row, i.e., colsb) are metadata that drives the execution of tile and accelerator instructions. In this way, a single instruction can launch autonomous multi-cycle execution in the tile and accelerator hardware. The palette value (palette_id) and metadata are held internally in a tile related control register (TILECFG). The TILECFG contents will be commensurate with that reported in the palette_table (see “CPUID—CPU Identification” in Chapter 1 for a description of the available parameters).

Intel AMX is an extensible architecture. New accelerators can be added, or the TMUL accelerator may be enhanced to provide higher performance. In these cases, the state (TILEDATA) provided by tiles may need to be made larger, either in one of the metadata dimensions (more rows or colsb) and/or by supporting more tile registers (names). The extensibility is carried out by adding new palette entries describing the additional state. Since execution is driven through metadata, an existing Intel AMX binary could take advantage of larger storage sizes and higher performance TMUL units by selecting the most powerful palette indicated by CPUID and adjusting loop and pointer updates accordingly.

Figure 3-1 shows a conceptual diagram of the Intel AMX architecture. An Intel architecture host drives the algorithm, the memory blocking, loop indices and pointer arithmetic. Tile loads and stores and accelerator commands are sent to multi-cycle execution units. Status, if required, is reported back. Intel AMX instructions are synchronous in the Intel architecture instruction stream and the memory loaded and stored by the tile instructions is coherent with respect to the host’s memory accesses. There are no restrictions on interleaving of Intel architecture and Intel AMX code or restrictions on the resources the host can use in parallel with Intel AMX (e.g., Intel AVX-512). There is also no architectural requirement on the Intel architecture compute capability of the Intel architecture host other than it supports 64-bit mode.

The following Intel® AMX instructions have moved to the Intel® 64 and IA-32 Architectures Software Developer’s Manual: LDTILECFG, STTILECFG, TDPBF16PS, TDPBSSD/TDPBSUD/TDPBUSD/TDPBUSD, TILELOAD/TILELOADDT1, TILERELEASE, TILESTORED, and TILEZERO.

The Intel Advanced Matrix Extensions introductory material and helper functions will be maintained here, as well as in the Intel® 64 and IA-32 Architectures Software Developer’s Manual, for the reader’s convenience. For information on Intel AMX and the XSAVE feature set, and recommendations for system software, see the latest version of the Intel® 64 and IA-32 Architectures Software Developer’s Manual.
Intel AMX instructions use new registers and inherit basic behavior from Intel architecture in the same manner that Intel SSE and Intel AVX did. Tile instructions include loads and stores using the traditional Intel architecture register set as pointers. The TMUL instruction set (defined to be CPUID bits AMX-BF16 and AMX-INT8) only supports reg-reg operations.

TILECFG is programmed using the LDTILECFG instruction. The selected palette defines the available storage and general configuration while the rest of the memory data specifies the number of rows and column bytes for each tile. Consistency checks are performed to ensure the TILECFG matches the restrictions of the palette. A General Protection fault (#GP) is reported if the LDTILECFG fails consistency checks. A successful load of TILECFG with a palette_id other than 0 is represented in this document with TILES_CONFIGURED = 1. When the TILECFG is initialized (palette_id = 0), it is represented in the document as TILES_CONFIGURED = 0. Nearly all Intel AMX instructions will generate a #UD exception if TILES_CONFIGURED is not equal to 1; the exceptions are those that do TILECFG maintenance: LDTILECFG, STTILECFG and TILERELEASE.

If a tile is configured to contain M rows by N column bytes, LDTILECFG will ensure that the metadata values are appropriate to the palette (e.g., that $M \leq 16$ and $N \leq 64$ for palette 1). The four $M$ and $N$ values can all be different as long as they adhere to the restrictions of the palette. Further dynamic checks are done in the tile and the TMUL instruction set to deal with cases where a legally configured tile may be inappropriate for the instruction operation. Tile registers can be set to ‘invalid’ by configuring the rows and colsb to ‘0’.

Tile loads and stores are strided accesses from the application memory to packed rows of data. Algorithms are expressed assuming row major data layout. Column major users should translate the terms according to their orientation.

TILELOAD* and TILESTORE* instructions are restartable and can handle (up to) 2*rows page faults per instruction. Restartability is provided by a start row parameter in the TILECFG register.

The TMUL unit is conceptually a grid of fused multiply-add units able to read and write tiles. The dimensions of the TMUL unit (tmul_maxk and tmul_maxn) are enumerated similar to the maximum dimensions of the tiles (see “CPUID—CPU Identification” in Chapter 1 for details).

The matrix multiplications in the TMUL instruction set compute $C[M][N] += A[M][K] \times B[K][N]$. The $M$, $N$, and $K$ values will cause the TMUL instruction set to generate a #UD exception if the dimensions do not match for matrix multiply or do not match the palette.

In Figure 3-2, the number of rows in tile B matches the $K$ dimension in the matrix multiplication pseudocode. $K$ dimensions smaller than that enumerated in the TMUL grid are also possible and any additional computation the TMUL unit can support will not affect the result.
The number of elements specified by colsb of the B matrix is also less than or equal to tmul_maxn. Any remaining values beyond that specified by the metadata will be set to zero.

The XSAVE feature sets supports context management of the new state defined for Intel AMX. This support is described in Section 3.2.

### 3.1.1 Tile Architecture Details

The supported parameters for the tile architecture are reported via CPUID; this includes information about how the number of tile registers (max_names) can be configured (the palette). Configuring the tile architecture is intended to be done once when entering a region of tile code using the LDTILECFG instruction specifying the selected palette and describing in detail the configuration for each tile. Incorrect assignments will result in a General Protection fault (#GP). Successful LDTILECFG initializes ( zeroes) TILEDATA.

Exiting a tile region is done with the TILERELEASE instruction. It takes no parameters and invalidates all tiles (indicating that the data no longer needs any saving or restoring). Essentially, it is an optimization of LDTILECFG with an implicit palette of 0.

For applications that execute consecutive Intel AMX regions with differing configurations, TILERELEASE is not required between them since the second LDTILECFG will clear all the data while loading the new configuration. There is no instruction set support for automatic nesting of tile regions, though with sufficient effort software can accomplish this by saving and restoring TILEDATA and TILECFG either through the XSAVE architecture or the Intel AMX instructions.

The tile architecture boots in its INIT state, with TILECFG and TILEDATA set to zero. A successfully executing LDTILECFG instruction to a non-zero palette sets the TILES_CONFIGURED=1, indicating the TILECFG is not in the INIT state. The TILERELEASE instruction sets TILES_CONFIGURED = 0 and initializes ( zeroes) TILEDATA.

---

**Figure 3-2. The TMUL Unit**

```c
for m < M: // time steps
  for k < K: // grid height
    for n < N: // SIMD dimension
      C[m][n] += VNNI_MUL(A[m][k], B[k][n])
```
To facilitate handling of tile configuration data, there is a STTILECFG instruction. If the tile configuration is in the INIT state (TILES_CONFIGURED == 0), then STTILECFG will write 64 bytes of zeros. Otherwise STTILECFG will store the TILECFG to memory in the format used by LDTILECFG.

3.1.2 TMUL Architecture Details

The supported parameters for the TMUL architecture are reported via CPUID; see “CPUID—CPU Identification” in Chapter 1, page 1-24, for details. These parameters include a maximum height (tmul_maxk) and a maximum SIMD dimension (tmul_maxn). The metadata that accompanies the srcdest, src1 and src2 tiles to the TMUL unit will be dynamically checked to see that they match the TMUL unit support for the data type and match the requirements of a meaningful matrix multiplication.

Figure 3-3 shows an example of the inner loop of an algorithm of using the TMUL architecture to compute a matrix multiplication. In this example, we use two result tiles, tmm0 and tmm1, from matrix C to accumulate the intermediate results. One tile from the A matrix (tmm2) is re-used twice as we multiply it by two tiles from the B matrix. The algorithm then advances pointers to load a new A tile and two new B tiles from the directions indicated by the arrows. An outer loop, not shown, adjusts the pointers for the C tiles.

```
LDTILECFG [rax]
// assume some outer loops driving the cache tiling (not shown)
{
   TILELOADD tmm0, [rsi+rdi]  // srcdst, RSI points to C, RDI is strided value
   TILELOADD tmm1, [rsi+rdi+N] // second tile of C, unrolling in SIMD dimension N
   MOV r14, 0
   LOOP:
      TILELOADD tmm2, [r8+r9]   // src2 is strided load of A, reused for 2 TMUL instr.
      TILELOADD tmm3, [r10+r11] // src1 is strided load of B
      TDPBUSD tmm0, tmm2, tmm3  // update left tile of C
      TILELOADD tmm3, [r10+r11+N] // src1 loaded with B from next rightmost tile
      TDPBUSD tmm1, tmm2, tmm3  // update right tile of C
      ADD r8, K                  // update pointers by constants known outside of loop
      ADD r10, K*r11
      ADD r14, K
      CMP r14, LIMIT
      JNE LOOP
   TILESTORED [rsi+rdi], tmm0 // update the C matrix in memory
   TILESTORED [rsi+rdi+M], tmm1
} // end of outer loop
TILERELEASE        // return tiles to INIT state
```

Figure 3-3. Matrix Multiply C+= A*B
3.1.3 Handling of Tile Row and Column Limits

Intel AMX operations will zero any rows and any columns beyond the dimensions specified by TILECFG. Tile operations will zero the data beyond the configured number of column bytes as each row is written. For example, with 64-byte rows and a tile configured with 10 rows and 48 columns, an operation writing dword elements would write each of the first 10 rows with 48 bytes of output/result data and zero the remaining 16 bytes in each row. Tile operations also fully zero any rows after the first 10 configured rows. When using a 1 KByte tile with 64-byte rows, there would be 16 rows, so in this example, the last 6 rows would also be zeroed.

Intel AMX instructions will always obey the metadata on reads and the zeroing rules on writes, and so a subsequent XSAVE would see zeros in the appropriate locations. Tiles that are not written by Intel AMX instructions between XRSTOR and XSAVE will write back with the same image they were loaded with regardless of the value of TILECFG.

3.1.4 Exceptions and Interrupts

Tile instructions are restartable so that operations that access strided memory can restart after page faults. To support restarting instructions after these events, the instructions store information in the TILECFG.start_row register. TILECFG.start_row indicates the row that should be used for restart; i.e., it indicates next row after the rows that have already been successfully loaded (on a TILELOAD) or written to memory (on a TILESTORE) and prevents repeating work that was successfully done.

The TMUL instruction set is not sensitive to the TILECFG.start_row value; this is due to there not being TMUL instructions with memory operands or any restartable faults.

3.2 OPERAND RESTRICTIONS

Floating-point exceptions, denormal handling, and floating-point rounding: some of the Intel AMX instructions operate on floating-point values. These instructions all function as if floating-point exceptions are masked, and use the round-to-nearest-even (RNE) rounding mode. They also do not set any of the floating-point exception flags in MXCSR. Table 3-1 describes the treatment of denormal inputs and outputs for Intel AMX operations.

<table>
<thead>
<tr>
<th>Data Type</th>

<td>Treated as zero</td>
<td>N/A</td>
</tr>
</tbody>
</table>

3.3 IMPLEMENTATION PARAMETERS

The parameters are reported via CPUID leaf 1DH. Index 0 reports all zeros for all fields.

```plaintext
define palette_table[id]:
    uint16_t total_tile_bytes
    uint16_t bytes_per_tile
    uint16_t bytes_per_row
    uint16_t max_names
    uint16_t max_rows
```
The tile parameters are set by LDTILECFG or XRSTOR* of TILECFG:

```plaintext
define tile[tid]:
    byte rows
    word colsb // bytes_per_row
    bool valid
```

### 3.4 HELPER FUNCTIONS

The helper functions used in Intel AMX instructions are defined below.

```plaintext
define write_row_and_zero(treg, r, data, nbytes):
    for j in 0 ... nbytes-1:
        treg.row[r].byte[j] := data.byte[j]

    // zero the rest of the row
    for j in nbytes ... palette_table[tilecfg.palette_id].bytes_per_row-1:
        treg.row[r].byte[j] := 0
```

```plaintext
define zero_upper_rows(treg, r):
    for i in r ... palette_table[tilecfg.palette_id].max_rows-1:
        for j in 0 ... palette_table[tilecfg.palette_id].bytes_per_row-1:
            treg.row[i].byte[j] := 0
```

```plaintext
define zero_tilecfg_start():
    tilecfg.start_row := 0
```

```plaintext
define zero_all_tile_data():
    if XCR0[TILEDATA]:
        b := CPUID(0xD,TILEDATA).EAX // size of feature
        for j in 0 ... b:
            TILEDATA.byte[j] := 0
```
3.5 NOTATION

Instructions described in this chapter follow the general documentation convention established in Intel® 64 and IA-32 Architectures Software Developer’s Manual Volume 2A. Additionally, Intel® Advanced Matrix Extensions use notation conventions as described below.

In the instruction encoding boxes, sibmem is used to denote an encoding where a MODRM byte and SIB byte are used to indicate a memory operation where the base and displacement are used to point to memory, and the index register (if present) is used to denote a stride between memory rows. The index register is scaled by the sib.scale field as usual. The base register is added to the displacement, if present.

In the instruction encoding, the MODRM byte is represented several ways depending on the role it plays. The MODRM byte has 3 fields: 2-bit MODRM.MOD field, a 3-bit MODRM.REG field and a 3-bit MODRM.RM field. When all bits of the MODRM byte have fixed values for an instruction, the 2-hex nibble value of that byte is presented after the opcode in the encoding boxes on the instruction description pages. When only some fields of the MODRM byte must contain fixed values, those values are specified as follows:

- If only the MODRM.MOD must be 0b11, and MODRM.REG and MODRM.RM fields are unrestricted, this is denoted as 11:rrr:bbb. The rrr correspond to the 3-bits of the MODRM.REG field and the bbb correspond to the 3-bits of the MODRM.RM field.
- If the MODRM.MOD field is constrained to be a value other than 0b11, i.e., it must be one of 0b00, 0b01, or 0b10, then we use the notation !(11).
- If the MODRM.REG field had a specific required value, e.g., 0b101, that would be denoted as mm:101:bbb.

NOTE

Historically the Intel® 64 and IA-32 Architectures Software Developer’s Manual only specified the MODRM.REG field restrictions with the notation /0 ... /7 and did not specify restrictions on the MODRM.MOD and MODRM.RM fields in the encoding boxes.

3.6 EXCEPTION CLASSES

Alignment exceptions: The Intel AMX instructions that access memory will never generate #AC exceptions.

### Description

These instructions perform matrix multiplication of two tiles containing complex elements and accumulate the results into a packed single precision tile. Each dword element in input tiles tmm2 and tmm3 is interpreted as a complex number with FP16 real part and FP16 imaginary part.

TCMMRLFP16PS calculates the real part of the result. For each possible combination of (row of tmm2, column of tmm3), the instruction performs a set of multiplication and accumulations on all corresponding complex numbers (one from tmm2 and one from tmm3). The real part of the tmm2 element is multiplied with the real part of the corresponding tmm3 element, and the negated imaginary part of the tmm2 element is multiplied with the imaginary part of the corresponding tmm3 elements. The two accumulated results are added, and then accumulated into the corresponding row and column of tmm1.

TCMMIMFP16PS calculates the imaginary part of the result. For each possible combination of (row of tmm2, column of tmm3), the instruction performs a set of multiplication and accumulations on all corresponding complex numbers (one from tmm2 and one from tmm3). The imaginary part of the tmm2 element is multiplied with the real part of the corresponding tmm3 element, and the real part of the tmm2 element is multiplied with the imaginary part of the corresponding tmm3 elements. The two accumulated results are added, and then accumulated into the corresponding row and column of tmm1.

"Round to nearest even" rounding mode is used when doing each accumulation of the FMA. Output denormals are always flushed to zero but FP16 input denormals are not treated as zero.

MXCSR is not consulted nor updated.

Any attempt to execute these instructions inside an Intel TSX transaction will result in a transaction abort.

### Operation

**TCMMIMFP16PS tsrdest, tsr1, tsr2**

// C = m x n (tsrdest), A = m x k (tsr1), B = k x n (tsr2)

# src1 and src2 elements are pairs of fp16

```plaintext
elements_src1 := tsr1.colsb / 4
elements_dest := tsrdest.colsb / 4
elements_temp := tsrdest.colsb / 2 // Count is in fp16 prior to horizontal
```

for m in 0 ... tsrdest.rows-1:
    temp[0 ... elements_temp-1] := 0
    for k in 0 ... elements_src1-1:
        for n in 0 ... elements_dest-1:
\[ s1e = \text{cvt\_fp16\_to\_fp32}(\text{tsrc1.row}[m].fp16[2\times k+0]) \quad \text{// real} \\
\]
\[ s2e = \text{cvt\_fp16\_to\_fp32}(\text{tsrc2.row}[k].fp16[2\times n+0]) \quad \text{// real} \\
\]
\[ s1o = \text{cvt\_fp16\_to\_fp32}(\text{tsrc1.row}[m].fp16[2\times k+1]) \quad \text{// imaginary} \\
\]
\[ s2o = \text{cvt\_fp16\_to\_fp32}(\text{tsrc2.row}[k].fp16[2\times n+1]) \quad \text{// imaginary} \\
\]

// FP32 FMA with DAZ=FTZ=1, RNE rounding.  
// MXCSR is neither consulted nor updated.

Description

This instruction performs a set of SIMD dot-products of two FP16 elements and accumulates the results into a packed single precision tile. Each dword element in input tiles tmm2 and tmm3 is interpreted as a FP16 pair. For each possible combination of (row of tmm2, column of tmm3), the instruction performs a set of SIMD dot-products on all corresponding FP16 pairs (one pair from tmm2 and one pair from tmm3), adds the results of those dot-products, and then accumulates the result into the corresponding row and column of tmm1.

"Round to nearest even" rounding mode is used when doing each accumulation of the Fused Multiply-Add (FMA). Output FP32 denormals are always flushed to zero. Input FP16 denormals are always handled and not treated as zero.

MXCSR is not consulted nor updated.

Any attempt to execute the TDPFP16PS instruction inside an Intel TSX transaction will result in a transaction abort.

Operation

TDPFP16PS tsrcdest, tsrc1, tsrc2

// C = m x n (tsrcdest), A = m x k (tsrc1), B = k x n (tsrc2)

# src1 and src2 elements are pairs of fp16
elements_src1 := tsrc1.colsb / 4
elements_src2 := tsrc2.colsb / 4
elements_dest := tsrcdest.colsb / 4
elements_temp := tsrcdest.colsb / 2 // Count is in fp16 prior to horizontal

for m in 0 ... tsrcdest.rows-1:
    temp[0 ... elements_temp-1] := 0
for k in 0 ... elements_src1-1:
    for n in 0 ... elements_dest-1:
        // For this operation:
        // Handle FP16 denominators. Not forcing input FP16 denorms to 0.
        // FP32 FMA with DAZ=FTZ=1, RNE rounding.
        // MXCSR is neither consulted nor updated.
        // No exceptions raised or denoted.

        temp1.fp32[2*n+0] += cvt_fp16_to_fp32(tsrc1.row[m].fp16[2*k+0] * cvt_fp16_to_fp32(tsrc2.row[k].fp16[2*n+0])

for n in 0 ... elements_dest-1:
    // DAZ=FTZ=1, RNE rounding.
    // MXCSR is neither consulted nor updated.
// No exceptions raised or denoted.

srcdest.row[m].fp32[n] := srcdest.row[m].fp32[n] + tmpf32

write_row_and_zero(tsrcdest, m, tmp, tsrcdest.colsb)

zero_upper_rows(tsrcdest, tsrcdest.rows)

zero_tileconfig_start()

Flags Affected

None.

Exceptions

AMX-E4; see Section 3.6, “Exception Classes” for details.
4.1 FEATURES TO DISABLE BUS LOCKS

Processors will assert a **bus lock** for a locked access in either of the following situations: (1) the access is to multiple cache lines (a **split lock**); or (2) the access with a memory type other than WB (a **UC lock**). Because bus locks may adversely affect performance in certain situations, processors may support two features that system software can use to disable bus locking. These are called **split-lock disable** and **UC-lock disable**.

A processor enumerates support for split-lock disable by setting bit 5 of the IA32_CORE_CAPABILITIES MSR (MSR index CFH). If this bit is read as 1, software can enable split-lock disable by setting bit 29 of the MSR_MEMORY_CTRL MSR (MSR index 33H). When this bit is set, a locked access to multiple cache lines causes an alignment-check exception (#AC) with a zero error code. The locked access does not occur.

While MSR_MEMORY_CTRL is not an architectural MSR, the behavior split-lock disable is consistent across processor models that enumerate support for it in the IA32_CORE_CAPABILITIES MSR.

Support for UC-lock disable is detailed in Section 4.2.

4.2 UC-LOCK DISABLE

A processor enumerates support for UC-lock disable either by setting IA32_CORE_CAPABILITIES[4] or by enumerating CPUID.(EAX=07H, ECX=2):EDX[bit 6] as 1. The latter form of enumeration (CPUID) is used beginning with processors based on Sierra Forest microarchitecture or Grand Ridge microarchitecture; earlier processors may use the former form (IA32_CORE_CAPABILITIES).

**NOTE**

If a processor enumerates support for UC-lock disable (in either way), software can enable UC-lock disable by setting MSR_MEMORY_CTRL[28]. When this bit is set, a locked access using a memory type other than WB causes a fault. The locked access does not occur. The specific fault that occurs depends on how UC-lock disable is enumerated:

- If IA32_CORE_CAPABILITIES[4] is read as 1, the UC lock results in a general-protection exception (#GP) with a zero error code.
- If CPUID.(EAX=07H, ECX=2):EDX[bit 6] is enumerated as 1, the UC lock results in an #AC with an error code with value 4.

---

1. The term “UC lock” is used because the most common situation regards accesses to UC memory. Despite the name, locked accesses to WC, WP, and WT memory also cause bus locks.
2. Other alignment-check exceptions occur only if CR0.AM = 1, EFLAGS.AC = 1, and CPL = 3. The alignment-check exceptions resulting from split-lock disable may occur even if CR0.AM = 0, EFLAGS.AC = 0, or CPL < 3.

Intel® Resource Director Technology (Intel® RDT) provides a number of monitoring and control capabilities for shared resources in multiprocessor systems. This chapter covers updates to the feature that will be available in future Intel processors, starting with brief descriptions followed by technical details.

5.1 INTEL® RDT FEATURE CHANGES

5.1.1 Intel® RDT on the 3rd generation Intel® Xeon® Scalable Processor Family

The 3rd generation Intel® Xeon® Scalable Processor Family based on Ice Lake Server microarchitecture adds the following Intel RDT enhancements:

- 32-bit MBM counters (vs. 24-bit in prior generations), and new CPUID enumeration capabilities for counter width.
- Second generation Memory Bandwidth Allocation (MBA): Introduces an advanced hardware feedback controller that operates at microsecond timescales, and software-selectable min/max throttling value resolution capabilities. Baseline descriptions of the MBA “throttling values” applied to the threads running on a core are described in the Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3B. Second generation MBA capabilities also add a work-conserving feature in which applications that frequently access the L3 cache may be throttled by a lesser amount until they exceed the user-specified memory bandwidth usage threshold, enhancing system throughput and efficiency, in addition to adding more precise calibration and controls. Certain BIOS implementations may further aid flexibility by providing selectable calibration profiles for various usages.
- 15 MBA / L3 CAT CLOS: Improved feature consistency and interface flexibility. The previous generation of processors supported 16 L3 CAT Class of Service tags (CLOS), but only 8 MBA CLOS. The changes in enumerated CLOS counts per-feature are enumerated in the processor as before, via CPUID.

5.1.2 Intel® RDT on Intel Atom® Processors, Including the P5000 Series

Intel Atom® processors, such as the P5000 series, based on Tremont microarchitecture add the following Intel RDT enhancements:

- L2 CAT/CDP: L2 CAT/CDP and L3 CAT/CDP may be enabled simultaneously on supported processors. As these are existing features defined in the Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3B, no new software enabling should be required.
- Supported processors match the capabilities of the 3rd generation Intel Xeon Scalable Processor Family based on Ice Lake Server microarchitecture, including traditional Intel RDT uncore features: L3 CAT/CDP, CMT, MBM, and second-generation MBA. As these features are architectural, no new software enabling is required. Related enhancements in Intel Xeon processors also carry forward to supported Intel Atom processors, with consistent software enabling. These features include 32-bit MBM counters, second generation MBA, and 15 MBA/L3 CAT CLOS.

5.1.3 Intel® RDT in Future Processors Based on Sapphire Rapids Server Microarchitecture

Processors based on Sapphire Rapids Server microarchitecture add the following Intel RDT enhancements:

- STLB QoS: Capability to manage the second-level translation lookaside buffer structure within the core (STLB) in a manner quite similar to CAT (CLOS-based, with capacity masks). This may enable software that is sensitive to TLB performance to achieve better determinism. This is a model-specific feature due to the microarchitectural nature of the STLB structure. The code regions of interest should be manually accessed.
5.1.4 Intel® RDT in Processors Based on Emerald Rapids Server Microarchitecture

Processors based on Emerald Rapids Server microarchitecture add the following Intel RDT enhancements:
- L2 CAT and CDP: Includes control over the L2 cache and the ability to partition the L2 cache into separate code and data virtual caches. No new software enabling is required; this is the same architectural feature described in the Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3B.

5.1.5 Future Intel® RDT

Future processors add the following Intel RDT enhancements:
- Third generation Memory Bandwidth Allocation (MBA): New per-logical-processor capability for bandwidth control (rather than the more coarse-grained core-level throttling value resolution in prior generations). This capability enables more precise bandwidth shaping and noisy neighbor control. Some portions of the control infrastructure now operate at core frequencies for controls that are responsive at the nanosecond level.

5.2 ENUMERABLE MEMORY BANDWIDTH MONITORING COUNTER WIDTH

Memory Bandwidth Monitoring (MBM) is an Intel RDT feature that tracks total and local bandwidth generated that misses the L3 cache.

The original Memory Bandwidth Monitoring (MBM) architectural definition defines counters of up to 62 bits in the IA32_QM_CTR MSR, and the first-generation MBM implementation provided 24-bit counters. Software is required to poll at $\geq 1$Hz to ensure that data is retrieved before a counter rollover occurs more than once. This $\geq 1$Hz sampling ensures that under worst-case conditions rollover between samples occurs at most once, but under typical conditions rollover often requires multiple seconds to occur.

As bandwidths scale, extensions to more elegantly handle high-bandwidth future systems are desirable. One of these extensions, detailed in this section, includes an enumerable MBM counter width. The 3rd generation Intel Xeon Scalable Processor Family, and corresponding Intel Atom processors, utilize this definition to implement 32-bit MBM counters, and future growth should be anticipated.

5.2.1 Memory Bandwidth Monitoring (MBM) Enabling

Memory Bandwidth Monitoring, like other Intel RDT features, uses CPUID for enumeration, and MSRs for assigning RMIDs and retrieving counter data. For CPUID enumeration details, see the Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 2A. For additional MBM details, see Chapter 18 in the Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3B.

5.2.2 Augmented MBM Enumeration and MSR Interfaces for Extensible Counter Width

A field is added to CPUID to enumerate the MBM counter width in platforms that support the extensible MBM counter width feature.

Before this point, CPUID.0F.[ECX=1]:EAX was reserved. This CPUID output register (EAX) is redefined to provide two new fields:
- Encode counter width as offset from 24b in bits[7:0].
- Enumeration of the presence of an overflow bit in the IA32_QM_CTR MSR via EAX bit[8].

See “CPUID—CPU Identification” in Chapter 1 for details.

In EAX bits 7:0, the counter width is encoded as an offset from 24b. A value of zero in this field means 24-bit counters are supported. A value of 8 indicates that 32-bit counters are supported, as in the 3rd generation Intel Xeon Scalable Processor Family.

With the addition of this enumerable counter width, the requirement that software poll at $\geq 1$Hz is removed. Software may poll at a varying rate with reduced risk of rollover, and under typical conditions rollover is likely to require hundreds of seconds (though this value is not explicitly specified and may vary and decrease in future processor
generations as memory bandwidths increase). If software seeks to ensure that rollover does not occur more than once between samples, then sampling at $\geq 1$Hz while consuming the enumerated counter widths' worth of data will provide this guarantee, for a specific platform and counter width, under all conditions.

Software that uses the MBM event retrieval MSR interface should be updated to comprehend this new format, which enables up to 62-bit MBM counters to be provided by future platforms. Higher-level software that consumes the resulting bandwidth values is not expected to be affected.

An overflow bit is defined in the IA32_QM_CTR MSR, bit 61, if CPUID.0F.[ECX=1]:EAX[bit 8] is set. This rollover bit will be set on overflow of the MBM counters and reset upon read. Current processors do not support this capability.

5.3 SECOND GENERATION MEMORY BANDWIDTH ALLOCATION

The second generation of Memory Bandwidth Allocation (MBA) is implemented in the 3rd generation Intel Xeon Scalable Processor Family, and related Intel Atom processors such as the P5000 Series. This enhanced MBA capability provides improved efficiency and accuracy in throttling, along with providing increased system throughput. Rather than a strict bandwidth control mechanism, a dynamic hardware controller is implemented, which can react to changing bandwidth conditions at the microsecond level.

Before using the second generation MBA feature, the MBA hardware controller requires a BIOS-assisted calibration process that may include inputs such as the number of memory channels populated and other system parameters; this is a change from the first generation of MBA. Intel BIOS reference code includes a default configuration that is recommended for general usage, and BIOS profiles may be created with alternate tuning values to optimize for certain usages (such as stricter throttling).

Second generation MBA moves from static throttling at the core/uncore interface, to a more dynamic control method based on a hardware controller that tracks actual DRAM bandwidth. This allows software that uses primarily the L3 cache to observe increased throughput for a given throttling level, or fine-grained throughput benefits for software that exhibits L3-bound phases. Due to the closer consideration of memory bandwidth loading, this enhancement may lead to an increase in system efficiency when using second generation MBA relative to prior implementations of the feature. Backward compatibility of the software interfaces is preserved, and second generation MBA changes manifest as enhancements atop the MBA feature baseline.

As with the prior generation feature, second generation MBA uses CPUID for enumeration, and throttling is performed using a mapping created from software thread-to-CLOS (in the IA32_PQR_ASSOC MSR), which is then mapped per-CLOS to delay values via the IA32_L2_QoS_Ext_BW_Thrtl_n MSRs. A privileged operating system or virtual machine manager software may specify a per-CLOS delay value, 0-90% bandwidth throttling for instance, though the max and granularity values are platform dependent and enumerated in CPUID.

5.3.1 Second Generation MBA Advantages

Additional features added over first generation MBA are described below.

1. Previously, only the maximum delay value across two CLOS on a physical core could be selected in MBA. Second generation MBA allows a minimum delay value to be selected instead, which may enhance usage with Intel® Hyper-Threading Technology.

2. Only a single preprogrammed calibration table was possible in first generation MBA, meaning different memory configurations had the potential for different linearity and percent delay value error values depending on the configuration. This is addressed by the BIOS support in the second generation of MBA, and certain BIOS implementations may program a different calibration table per memory configuration, for instance.

3. The second generation MBA controller provides the ability to more closely monitor the memory bandwidth loading and deliver more optimal results.

4. The new MBA hardware controller reduces the need for a fine-grained software controller to manage application phases for optimal efficiency. Note that a software controller may still be valuable to translate MBA throttling values to bandwidths in GB/s or application Service Level Objectives (SLOs), such as performance targets.
The second generation MBA implementation is shown in Figure 5-1. The feature now operates through the use of an advanced new hardware controller and feedback mechanism, which allows automated hardware monitoring and control around the user-provided delay value set point. This set point and associated throttling value infrastructure remains unchanged from prior generation MBA, preserving software compatibility.

MBA enhancements, in addition to the new hardware controller, include:

   - MBA 1.0 implementation statically picks the max MBA Throttling Level (MBAThrotLvl) across the threads running on a core (by calculating value = max(MBAThrotLvl(CLOS[thread0]), MBAThrotLvl(CLOS[thread1]))).
   - Software may have the option to pick either maximum or minimum delay to be resolved and applied across the threads; maximum value remains the default.

2. Increasing CLOSIDs from 8 to 15.
   - Previous generations of microarchitecture provided 8 CLOS tags for MBA.
   - The 3rd generation Intel Xeon Scalable Processor Family and related Intel Atom processors, such as the P5000 Series, increase this value to 15 (also consistent with L3 CAT).

5.3.2 Second Generation MBA Software-Visible Changes

A new model-specific MSR is introduced with second generation MBA to allow software to select from the maximum (default) or minimum of resolved throttling values (see formula above). This capability is controlled via a bit in the new MBA_CFG MSR, shown in Table 5-1.
Note that bit[0] for min/max configuration is supported in second generation MBA, but is removed in third generation MBA when the controller logic becomes capable of managing throttling values on a per-logical-processor basis. The transient nature of this enhancement is why the min/max control remains model-specific.

To enumerate and manage support for the model-specific min/max feature, software may use processor family/model/stepping to match supported products, then CPUID to later detect enhanced third generation MBA support.

### 5.4 THIRD GENERATION MEMORY BANDWIDTH ALLOCATION

The third generation MBA feature on future processors based on Granite Rapids microarchitecture further enhances the feature with per-logical-processor control and a further improved controller design. Total memory bandwidth (all LLC miss traffic) is now managed by MBA 3.0.

This implementation follows the past MBA precedent of delivering significant enhancements without a major software overhaul, and while preserving backward compatibility.

#### 5.4.1 Third Generation MBA Hardware Changes

The third generation of MBA builds upon the hardware controller introduced in the previous generation, which enabled significant system-level benefits, by providing the capability to independently throttle logical processors, rather than more coarse-grained per-core throttling in prior generations. Throttling values are no longer selected as the “min” or “max” of the two throttling values for the threads running on the core; instead throttling values are independently and directly applied to each logical processor.

While this enhancement means that more direct throttling of threads is possible, future usage guidance may be necessary to help explain the effects of Intel® Hyper-Threading Technology contention vs. cache and memory contention, and how these effects may be understood by software.

#### 5.4.2 Third Generation MBA Software-Visible Changes

In order to allow software to change its tuning behavior and detect that per-logical-processor throttling is supported on a particular product generation, a new CPUID bit is added to the MBA CPUID leaf to indicate support. See “CPUID—CPU Identification” in Chapter 1 for details.

Despite another significant improvement of the hardware controller infrastructure architecture and improved capabilities, controller responsiveness, new internal microarchitecture, and transient-arresting capabilities, no new software interface changes are required to make use of the third generation of MBA relative to prior generations. Software previously using the second generation MBA min/max selection capability should discontinue use of the MBA_CFG MSR. MBA 3.0 is the default mode of operation on the future Granite Rapids Server microarchitecture.

### 5.5 FUTURE MBA ENHANCEMENTS

Further model-specific enhancements to MBA may be introduced on the Granite Rapids Server microarchitecture to support specific usages; contact your Intel representative for details.
This chapter describes a new feature called **linear-address masking (LAM)**. LAM modifies the checking that is applied to 64-bit linear addresses, allowing software to use of the untranslated address bits for metadata.

In 64-bit mode, linear address have 64 bits and are translated either with 4-level paging, which translates the low 48 bits of each linear address, or with 5-level paging, which translates 57 bits. The upper linear-address bits are reserved through the concept of **canonicality**. A linear address is 48-bit canonical if bits 63:47 of the address are identical; it is 57-bit canonical if bits 63:56 are identical. (Clearly, any linear address that is 48-bit canonical is also 57-bit canonical.) When 4-level paging is active, the processor requires all linear addresses used to access memory to be 48-bit canonical; similarly, 5-level paging ensures that all linear addresses are 57-bit canonical.

Software usages that associate metadata with a pointer might benefit from being able to place metadata in the upper (untranslated) bits of the pointer itself. However, the canonicality enforcement mentioned earlier implies that software would have to mask the metadata bits in a pointer (making it canonical) before using it as a linear address to access memory. LAM allows software to use pointers with metadata without having to mask the metadata bits. With LAM enabled, the processor masks the metadata bits in a pointer before using it as a linear address to access memory.

LAM is supported only in 64-bit mode and applies only addresses used for data accesses. LAM does not apply to addresses used for instruction fetches or to those being loaded into the RIP register (e.g., as targets of jump and call instructions).

### 6.1 ENUMERATION, ENABLING, AND CONFIGURATION

LAM support by the processor is enumerated by the CPUID feature flag CPUID.(EAX=07H, ECX=01H):EAX.LAM[bit 26]. Enabling and configuration of LAM is controlled by the following new bits in control registers: CR3[62] (LAM_U48), CR3[61] (LAM_U57), and CR4[28] (LAM_SUP). The use of these control bit is explained below.

LAM supports configurations that differ regarding which pointer bits are masked and can be used for metadata. With **LAM48**, pointer bits in positions 62:48 are masked (resulting in a **LAM width** of 15); with **LAM57**, pointer bits in positions 62:57 are masked (a LAM width of 6). The LAM width may be configured differently for user and supervisor pointers. LAM identifies pointer as a user pointer if bit 63 of the pointer is 0 and as a supervisor pointer if bit 63 of the pointer is 1.

CR3.LAM_U48 and CR3.LAM_U57 enable and configure LAM for user pointers:

- If CR3.LAM_U48 = CR3.LAM_U57 = 0, LAM is not enabled for user pointers.
- If CR3.LAM_U48 = 1 and CR3.LAM_U57 = 0, LAM48 is enabled for user pointers (a LAM width of 15).
- If CR3.LAM_U57 = 1, LAM57 applies to user pointers (a LAM width of 6; CR3.LAM_U48 is ignored).

CR4.LAM_SUP enables and configures LAM for supervisor pointers:

- If CR3.LAM_SUP = 0, LAM is not enabled for supervisor pointers.
- If CR3.LAM_SUP = 1, LAM is enabled for supervisor pointers with a width determined by the paging mode:
  - If 4-level paging is enabled, LAM48 is enabled for supervisor pointers (a LAM width of 15).
  - If 5-level paging is enabled, LAM57 is enabled for supervisor pointers (a LAM width of 6).

Note that the LAM identification of a pointer as user or supervisor is based solely on the value of pointer bit 63 and does not, for the purposes of LAM, depend on the CPL.

### 6.2 TREATMENT OF DATA ACCESSES WITH LAM ACTIVE FOR USER POINTERS

Recall that, without LAM, canonicality checks are defined so that 4-level paging requires bits 63:47 of each pointer to be identical, while 5-level paging requires bits 63:56 to be identical. LAM allows some of these bits to be used as metadata by modifying canonicality checking.
When LAM48 is enabled for user pointers (see Section 6.1), the processor allows bits 62:48 of a user pointer to be used as metadata. Regardless of the paging mode, the processor performs a modified canonicality check that enforces that bit 47 of the pointer matches bit 63. As illustrated in Figure 6-1, bits 62:48 are not checked and are thus available for software metadata. After this modified canonicality check is performed, bits 62:48 are masked by sign-extending the value of bit 47 (0), and the resulting (48-bit canonical) address is then passed on for translation by paging.

(Note also that, without LAM, canonicality checking with 5-level paging does not apply to bit 47 of a user pointer; when LAM48 is enabled for user pointers, bit 47 of a user pointer must be 0. Note also that linear-address bits 56:47 are translated by 5-level paging. When LAM48 is enabled for user pointers, these bits are always 0 in any linear address derived from a user pointer: bits 56:48 of the pointer contained metadata, while bit 47 is required to be 0.)

When LAM57 is enabled for user pointers, the processor allows bits 62:57 of a user pointer to be used as metadata. With 5-level paging, the processor performs a modified canonicality check that enforces only that bit 56 of the pointer matches bit 63. As illustrated in Figure 6-2, bits 62:57 are not checked and are thus available for software metadata. After this modified canonicality check is performed, bits 62:57 are masked by sign-extending the value of bit 56 (0), and the resulting (57-bit canonical) address is then passed on for translation by 5-level paging.

When LAM57 is enabled for user pointers with 4-level paging, the processor performs a modified canonicality check that enforces only that bits 56:47 of a user pointer match bit 63. As illustrated in Figure 6-3, bits 62:57 are not checked and are thus available for software metadata. After this modified canonicality check is performed, bits 62:57 are masked by sign-extending the value of bit 56 (0), and the resulting (48-bit canonical) address is then passed on for translation by 4-level paging.
6.3 TREATMENT OF DATA ACCESSES WITH LAM ACTIVE FOR SUPERVISOR POINTERS

As with user pointers (Section 6.2), LAM can be configured to modify canonicality checking to allow use of metadata in supervisor pointers. For supervisor pointers, the number of metadata bits (the LAM width) available depends on the paging mode active: with 5-level paging, enabling LAM for supervisor pointers results in LAM57; with 4-level paging, it results in LAM48 (see Section 6.1).

When LAM57 is enabled for supervisor pointers (5-level paging), the processor performs a modified canonicality check that enforces only that bit 56 of a supervisor pointer matches bit 63. As illustrated in Figure 6-4, bits 62:57 are not checked and are thus available for software metadata. After this modified canonicality check is performed, bits 62:57 are masked by sign-extending the value of bit 56 (1), and the resulting (57-bit canonical) address is then passed on for translation by 5-level paging.

When LAM48 is enabled for supervisor pointers (4-level paging), the processor performs a modified canonicality check that enforces only that bit 47 of a supervisor pointer matches bit 63. As illustrated in Figure 6-5, bits 62:48 are not checked and are thus available for software metadata. After this modified canonicality check is performed, bits 62:48 are masked by sign-extending the value of bit 47 (1), and the resulting (48-bit canonical) address is then passed on for translation by 4-level paging.
LINEAR ADDRESS MASKING (LAM)

6.4 CANONICALITY CHECKING FOR DATA ADDRESSES WRITTEN TO CONTROL Registers AND MSRS

Processors that support LAM continue to require the addresses written to control registers or MSRs be 57-bit canonical if the processor supports 5-level paging or 48-bit canonical if it supports only 4-level paging; LAM masking is not performed on these writes. Similarly, LAM masking does not apply to loads of the SSP register. When the contents of such registers are used as pointers to access memory, the processor performs canonicality checking and masking based on paging mode and LAM mode configuration active at the time of access.

6.5 PAGING INTERACTIONS

As explained in Section 6.2 and Section 6.3, LAM masks certain bits in a pointer by sign-extension, resulting in a linear address to be translated by paging.

In most cases, the address bits in the masked positions are not used by address translation. However, if 5-level paging is active and LAM48 is enabled for user pointers, bit 47 of a user pointer must be zero and is extended over bits 62:48 to form a linear address — even though bits 56:48 are used by 5-level paging. This implies that, when LAM48 is enabled for user pointers, bits 56:47 are 0 in any linear address translated for a user pointer.

Page faults report the faulting linear address in CR2. Because LAM masking (by sign-extension) applies before paging, the faulting linear address recorded in CR2 does not contain the masked metadata.

The INVLPG instruction is used to invalidate any translation lookaside buffer (TLB) entries for a memory address specified with the source operand. LAM does not apply to the specified memory address. Thus, in 64-bit mode, if the memory address specified is in non-canonical form then the INVLPG is the same as a NOP.

The INVPCID instruction invalidates mappings in the TLB and paging structure caches based on the processor context identifier (PCID). The INVPCID descriptor provides the memory address to invalidate when the descriptor is of type 0 (individual-address invalidation). LAM does not apply to the specified memory address, and in 64-bit mode if this memory address is in non-canonical form then the processor generates a #GP(0) exception.

6.6 VMX INTERACTIONS

6.6.1 Guest Linear Address

Certain VM exits save in a VMCS field the guest linear address pertaining to the VM exit. Because such a linear address results from masking the original pointer, the processor does not report the masked metadata in the VMCS. The guest linear address saved is always the result of the sign-extension described in Section 6.2 and Section 6.3.
6.6.2 VM-Entry Checking of Values of CR3 and CR4

VM entry checks the values of the CR3 and CR4 fields in the guest-area and host-state area of the VMCS. In particular, the bits in these fields that correspond to bits reserved in the corresponding register are checked and must be 0.

On processors that enumerate support for LAM (Section 6.1), VM entry allows bits 62:61 to be set in either CR3 field and allows bit 28 to be set in either CR4 field.

6.6.3 CR3-Target Values

If the “CR3-load exiting” VM-execution control is 1, execution of MOV to CR3 in VMX non-root operation causes a VM exit unless the value of the instruction’s source operand is equal to one of the CR3-target values specified in the VMCS.

Processor support for LAM does not change this behavior. The comparison of the instruction source operand to each of the CR3-target values considers all 64 bits, including the two new bits that determine LAM enabling for user pointers (see Section 6.1).

6.6.4 Hypervisor-Managed Linear Address Translation (HLAT)

Hypervisor-managed linear-address translation (HLAT) is enabled when the “enable HLAT” tertiary processor-based VM-execution control is 1.

When HLAT is enabled for a guest, the processor translates a linear address using HLAT paging structures (instead of guest paging structures) if the address matches the Protected Linear Range (PLR). When LAM is active, it is the linear address (derived from a pointer by masking) that is checked for a PLR match.

The hierarchy of HLAT paging structures is located using a guest-physical address in the VMCS (instead of the guest-physical address in CR3). Nevertheless, LAM enabling and configuration for user pointers is based on the value of CR3[62:61] (see Section 6.1) even when the guest-physical address in CR3 is not used for translating the linear addresses derived from user pointers.

6.7 DEBUG AND TRACING INTERACTIONS

6.7.1 Debug Registers

Debug registers DR0-DR3 can be programmed with linear addresses that are matched against memory accesses for data breakpoints or instruction breakpoints. When LAM is active, it is the linear address (derived from a pointer by masking) that is checked for matching the contents of the debug registers.

6.7.2 Intel® Processor Trace

Intel Processor Trace supports a CR3-filtering mechanism by which generation of packets containing architectural states can be enabled or disabled based on the value of CR3 matching the contents of the IA32_RTIT_CR3_MATCH MSR. On processors that support LAM, bits 62:61 of the CR3 (see Section 6.1) must also match bits 62:61 of this MSR to enable tracing.

6.8 INTEL® SGX INTERACTIONS

Memory operands of ENCLS, ENCLU, and ENCLV that are data pointers follow the LAM architecture and mask suitably. Code pointers continue to not mask metadata bits. ECREATE does not mask BASEADDR specified in SECS, and the unmasked BASEADDR must be canonical.

Two new SECS attribute bits are defined for LAM support in enclave mode:

**LINEAR ADDRESS MASKING (LAM)**

- **ATTRIBUTES.LAM_U48** (bit 9) - Activate LAM for user data pointers and use of bits 62:48 as masked metadata in enclave mode. This bit can be set if CPUID.(EAX=12H, ECX=01H):EAX[9] is 1.
- **ATTRIBUTES.LAM_U57** (bit 8) - Activate LAM for user data pointers and use of bits 62:57 as masked metadata in enclave mode. This bit can be set if CPUID.(EAX=12H, ECX=01H):EAX[8] is 1.

ECREATE causes #GP(0) if ATTRIBUTE.LAM_U48 bit is 1 and CPUID.(EAX=12H, ECX=01H):EAX[9] is 0, or if ATTRIBUTE.LAM_U57 bit is 1 and CPUID.(EAX=12H, ECX=01H):EAX[8] is 0.

During enclave execution, accesses using linear addresses are treated as if CR3.LAM_U48 = SECS.ATTRIBUTES.LAM_U48, CR3.LAM_U57 = SECS.ATTRIBUTES.LAM_U57, and CR3.LAM_SUP = 0. The actual value of CR3 is not changed. This implies that, during enclave execution, if SECS.ATTRIBUTES.LAM_U57 = 1, LAM57 is enabled for user pointers during enclave execution and, if SECS.ATTRIBUTES.LAM_U57 = 0 and SECS.ATTRIBUTES.LAM_U48 = 1, then LAM48 is enabled for user pointers. If SECS.ATTRIBUTES.LAM_U57 = SECS.ATTRIBUTES.LAM_U48 = 0, LAM is not enabled for user pointers.

When in enclave mode, supervisor data pointers are not subject to any masking.

The following ENCLU leaf functions check for linear addresses to be within the ELRANGE. When LAM is active, this check is performed on the linear addresses that result from masking metadata bits in user pointers used by the leaf functions.
- **EACCEPT**
- **EACCEPTCOPY**
- **EGETKEY**
- **EMODPE**
- **EREPORT**

The following linear address fields in the Intel SGX data structures hold linear addresses that are either loaded into the EPCM or are written out from the EPCM and do not contain any metadata.
- **SECS.BASEADDR**
- **PAGEINFO.LINADDR**

### 6.9 SYSTEM MANAGEMENT MODE (SMM) INTERACTIONS

On processors that enumerate support for LAM (Section 6.1), RSM allows restoring CR3 with a value that sets either or both bit 62 and bit 61 and restoring a value of CR4 with a value that sets bit 28.
All changes to existing operation are highlighted in violet.

**Description**

Fetches the line of data or code (instructions’ bytes) from memory that contains the byte specified with the source operand to a location in the cache hierarchy specified by a locality hint:

- **T0** (temporal data)—prefetch data into all levels of the cache hierarchy.
- **T1** (temporal data with respect to first level cache misses)—prefetch data into level 2 cache and higher.
- **T2** (temporal data with respect to second level cache misses)—prefetch data into level 3 cache and higher, or an implementation-specific choice.
- **NTA** (non-temporal data with respect to all cache levels)—prefetch data into non-temporal cache structure and into a location close to the processor, minimizing cache pollution.
- **IT0** (temporal code)—prefetch code into all levels of the cache hierarchy.
- **IT1** (temporal code with respect to first level cache misses)—prefetch code into all but the first-level of the cache hierarchy.

The source operand is a byte memory location. (The locality hints are encoded into the machine level instruction using bits 3 through 5 of the ModR/M byte.) Some locality hints may prefetch only for RIP-relative memory addresses; see additional details below. The address to prefetch is NextRIP + 32-bit displacement, where NextRIP is the first byte of the instruction that follows the prefetch instruction itself.

If the line selected is already present in the cache hierarchy at a level closer to the processor, no data movement occurs. Prefetches from uncacheable or WC memory are ignored.
The PREFETCHh instruction is merely a hint and does not affect program behavior. If executed, this instruction moves data closer to the processor in anticipation of future use.

The implementation of prefetch locality hints is implementation-dependent, and can be overloaded or ignored by a processor implementation. The amount of data or code lines prefetched is also processor implementation-dependent. It will, however, be a minimum of 32 bytes. Additional details of the implementation-dependent locality hints are described in Section 7.4 of Intel® 64 and IA-32 Architectures Optimization Reference Manual.

It should be noted that processors are free to speculatively fetch and cache data from system memory regions that are assigned a memory-type that permits speculative reads (that is, the WB, WC, and WT memory types). A PREFETCHh instruction is considered a hint to this speculative behavior. Because this speculative fetching can occur at any time and is not tied to instruction execution, a PREFETCHh instruction is not ordered with respect to the fence instructions (MFENCE, SFENCE, and LFENCE) or locked memory references. A PREFETCHh instruction is also unordered with respect to CLFLUSH and CLFLUSHOPT instructions, other PREFETCHh instructions, or any other general instruction. It is ordered with respect to serializing instructions such as CPUID, WRMSR, OUT, and MOV CR. PREFETCHITO/1 apply when in 64-bit mode with RIP-relative addressing; they stay NOPs otherwise. For optimal performance, the addresses used with these instructions should be the starting byte of a real instruction. PREFETCHITO/1 instructions are enumerated by CPUID.(EAX=07H, ECX=01H).EDX.PREFETCHI[bit 14].The encodings stay NOPs in processors that do not enumerate these instructions.

### Operation

FETCH (m8);

### Intel C/C++ Compiler Intrinsic Equivalent

```c
void _mm PREFETCH (char *p, int i)
```

The argument "*p" gives the address of the byte (and corresponding cache line) to be prefetched. The value "i" gives a constant (_MM_HINT_T0, _MM_HINT_T1, _MM_HINT_T2, or _MM_HINT_NTA, _MM_HINT_IT0, _MM_HINT_IT1) that specifies the type of prefetch operation to be performed.

### Numeric Exceptions

None.

### Exceptions (All Operating Modes)

#UD If the LOCK prefix is used.
The next generation Performance Monitoring Unit (PMU) offers additional enhancements beyond what is available in both the 12th generation Intel® Core™ processor based on Alder Lake performance hybrid architecture and the 13th generation Intel® Core™ processor:

- Timed PEBS
- New True-View Enumeration Architecture
  - General-Purpose Counters
  - Fixed-Function Counters
  - Architectural Performance Monitoring Events
    - Topdown Microarchitecture Analysis (TMA) Level 1 Architectural Performance Monitoring Events
  - Non-Architectural Capabilities
  - Counters Snapshotting and PEBS Format 6

### 8.1 NEW ENUMERATION ARCHITECTURE

A new Architectural Performance Monitoring Extended (ArchPerfmonExt) Leaf 23H is added to the CPUID instruction for enhanced enumeration of PMU architectural features; see Chapter 1, "Architectural Performance Monitoring Extended Main Leaf (Initial EAX Value = 23H, ECX = 0)" on page 26 for details. Additionally, the IA32_PERF_CAPABILITIES MSR enhances enumeration for PMU non-architectural features.

**NOTE**

CPUID leaf 0AH continues to report useful attributes, such as architectural performance monitoring version ID and counter width (# bits).

CPUID leaf 23H enhances previous enumeration of PMU capabilities:

- Employs CPUID sub-leafing to accommodate future PMU extensions.
- Exposes true-view resources per logical processor.
- Introduces a bitmap (true-view) enumeration of general-purpose counters availability.
- A bitmap (true-view) enumeration of fixed-function counters availability.
- A bitmap (true-view) enumeration of architectural performance monitoring events.

Processors that support this enhancement set CPUID.(EAX=07H, ECX=01H):EAX.ArchPerfmonExt[bit 8]. Additionally, the IA32_PERF_CAPABILITIES MSR enhances enumeration for PMU non-architectural features (see Section 8.1.6).

#### 8.1.1 CPUID Sub-Leafing

CPUID leaf 23H contains additional architectural PMU capabilities. This leaf supports sub-leafing, providing each distinct PMU feature with an individual sub-leaf for enumerating its details.

The availability of sub-leaves is enumerated via CPUID.(EAX=23H, ECX=0H):EAX. For each bit $n$ set in this field, sub-leaf $n$ under CPUID leaf 23H is supported.

1. The next generation PMU incorporates PEBS_FMT=5h as described in Section 20.6.2.4.2 of the Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3B.
8.1.2 Reporting Per Logical Processor

CPUID leaf 23H provides a true-view of per logical processor PMU capabilities. This leaf reports the actual support of the individual logical processor that the CPUID instruction was executed on; this applies to all sub-leaves.

Software must not make assumptions that CPUID leaf 23H would report any value the same on another logical processor. It is required to read CPUID leaf 23H on every logical processor and program that logical processor only according to the values returned by the CPUID leaf 23H directly executed upon it. It is a requirement of software to compare and determine common features between logical processors if required by iterating over each logical processor’s CPUID leaf 23H.

Conversely, CPUID leaf 0AH provides a maximum common set of capabilities across logical processors when a feature is not supported by all logical processors.

NOTE
Locating a PMU feature under CPUID leaf 023H alerts software that the features may not be supported uniformly across all logical processors.

8.1.3 General-Purpose Counters Bitmap

CPUID.(EAX=23H, ECX=01H):EAX reports a bitmap for available general-purpose counters. (CPUID leaf 0AH reports only the total number of common programmable counters).

This capability enables a virtual-machine monitor to reserve lower-index counters for its own use, while exposing higher-index counters to guest software. This is especially important should the general-purpose counters not be fully homogeneous.

Software should utilize the new bitmap reporting, including for detecting the number of available general-purpose counters. To facilitate this transition, the number of general-purpose counters in CPUID leaf 0AH will not go beyond eight, even if the processor has support for more than eight general-purpose counters.

Note that programmable counters that are exclusively enumerated in CPUID.(EAX=23H, ECX=01H):EAX may not support the legacy MSR address range; see Section 8.5, “PerfMon MSRs Aliasing,” for details.

8.1.4 Fixed-Function Counters True-View Bitmap

CPUID.(EAX=23H, ECX=01H):EBX reports a bitmap for available fixed-function counters. (CPUID leaf 0AH reports the common number of contiguous fixed-function counters in addition to a common bitmap of fixed-function counters availability.)

This capability enables privileged software to expose per logical processor enumeration of fixed-function counters. This is especially important should the fixed-function counters not be available on all logical processors.

Note that programmable counters that are exclusively enumerated in CPUID.(EAX=23H, ECX=01H):EAX may not support the legacy MSR address range; see Section 8.5, “PerfMon MSRs Aliasing,” for details.

8.1.5 Architectural Performance Monitoring Events Bitmap

CPUID.(EAX=23H, ECX=03H):EAX provides a true-view of per logical processor available architectural performance monitoring events. For each bit \( n \) set in this field, the processor supports Architectural Performance Monitoring Event of index \( n \) (positive polarity).

Conversely, CPUID leaf 0AH provides a maximum common set of architectural performance monitoring events supported by all logical processors, where if bit \( n \) is set, it denotes the processor does not necessarily support Architectural Performance Monitoring Event of index \( n \) on all logical processors (negative polarity).

8.1.6 Non-Architectural Performance Capabilities

The IA32_PERF_CAPABILITIES MSR provides enumeration of non-architectural PMU features. With next generation PMU, the documentation is updated with a per-field attribute to indicate whether the reporting is common or true-
view. That is, some IA32_PERF_CAPABILITIES fields report the actual support of the individual logical processor the RDMSR instruction was executed on. The IA32_PERF_CAPABILITIES fields are shown in Table 8-1.

8.2.1  **Topdown Microarchitecture Analysis Level 1**

8.2.1.1  **Topdown Backend Bound – Event Select A4H, Umask 02H**
This event counts a subset of the Topdown Slots event that was not consumed by the back-end pipeline due to lack of back-end resources, as a result of memory subsystem delays, execution unit limitations, or other conditions.

The count may be distributed among unhalted logical processors that share the same physical core, in processors that support Intel® Hyper-Threading Technology.

Software can use this event as the numerator for the Backend Bound metric (or top-level category) of the Topdown Microarchitecture Analysis method.

8.2.1.2  **Topdown Bad Speculation – Event Select 73H, Umask 00H**
This event counts a subset of the Topdown Slots event that was wasted due to incorrect speculation as a result of incorrect control-flow or data speculation. Common examples include branch mispredictions and memory ordering clears.

The count may be distributed among impacted logical processors that share the same physical core, for some processors that support Intel Hyper-Threading Technology.

Software can use this event as the numerator for the Bad Speculation metric (or top-level category) of the Topdown Microarchitecture Analysis method.

8.2.1.3  **Topdown Frontend Bound – Event Select 9CH, Umask 01H**
This event counts a subset of the Topdown Slots event that had no operation delivered to the back-end pipeline due to instruction fetch limitations when the back-end could have accepted more operations. Common examples include instruction cache misses and x86 instruction decode limitations.

The count may be distributed among unhalted logical processors that share the same physical core, in processors that support Intel Hyper-Threading Technology.

Software can use this event as the numerator for the Frontend Bound metric (or top-level category) of the Topdown Microarchitecture Analysis method.

8.2.1.4  **Topdown Retiring – Event Select C2H, Umask 02H**
This event counts a subset of the Topdown Slots event that is utilized by operations that eventually get retired (committed) by the processor pipeline. Usually, this event positively correlates with higher performance as measured by the instructions-per-cycle metric.

Software can use this event as the numerator for the Retiring metric (or top-level category) of the Topdown Microarchitecture Analysis method.

8.3  **PROCESSOR EVENT BASED SAMPLING (PEBS) ENHANCEMENTS**

8.3.1  **Timed Processor Event Based Sampling**
Timed Processor Event Based Sampling (Timed PEBS) enables recording of time in every PEBS record. It extends all PEBS records with timing information in a new "Retire Latency" field that is placed in the Basic Info group of the PEBS record as shown in Table 8-3.
The Retire Latency field reports the number of Unhalted Core Cycles between the retirement of the current instruction (as indicated by the Instruction Pointer field of the PEBS record) and the retirement of the prior instruction. All ones are reported when the number exceeds 16 bits.

Processors that support this enhancement set a new bit: IA32_PERF_CAPABILITIES.PEBS_TIMING_INFO[bit 17].

NOTE
Timed PEBS is not supported when PEBS is programmed on fixed-function counter 0. The Retire Latency field of such record is undefined.

8.3.2 Counters Snapshotting
Counters Snapshotting extends Adaptive PEBS with the PEBS Counters and Metrics group. This extension enables software to capture programmable counters, fixed-function counters, and performance metrics in the PEBS record. This section assumes that the reader is familiar with Adaptive PEBS, which is documented in Section 20.9, “PEBS Facility,” in the Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3B.

8.3.2.1 Updated PEBS_DATA_CFG MSR
Bits in MSR_PEBS_DATA_CFG can be set to include data field blocks/groups into adaptive records. Specifically:
- The Basic Info group is always included in the record.
- The number of LBR entries included in the record is configurable.
- Which counters are included in the Counters group is configurable.

8.3.2.2 Counters and Metrics Group

To capture the counters group, either the COUNTERS bit or the METRICS bit must be enabled in MSR_PEBS_DATA_CFG. The group allows recording of the IA32_PMCx MSRs, IA32_FIXED_CTRx MSRs, and the Performance Metrics.

The counters group first captures a 128-bit header with the bit vector of the counters that are captured later. The format of the counters header and the payload is shown in Table 8-5.

The group is available starting with IA32_PERF_CAPABILITIES.PEBS_FMT of 6. Additionally, the group is available in a subset of processors with a CPUID signature value of DisplayFamily_DisplayModel 06_C5H or 06_C6H (though they report IA32_PERF_CAPABILITIES.PEBS_FMT as 5).

IA32_PMCx will be captured if both Counters and MSR_PEBS_DATA_CFG bit 32 + x are set. In this case, the PMC BitVector field bit x will be set too.

IA32_FIXED_CTRx will be captured if both Counters and MSR_PEBS_DATA_CFG bit 48 + x are set. In this case, the FIXED_CTR BitVector field bit x will be set too.

The performance metrics will be recorded if both Metrics and MSR_PEBS_DATA_CFG bit 51 (the bit used for IA32_FIXED_CTR3) are set. The Metrics record will have two 64-bit fields, MSR_PERF_METRICS and the PERF_METRICS_BASE that is derived from IA32_FIXED_CTR3. In this case, the Metrics BitVector will be 3. Note that MSR_PERF_METRICS and the IA32_FIXED_CTR3 MSR will be cleared after they are recorded.

Size of the group can be calculated in bytes by: 16 + popcount(BitVectors[127:0]) * 8.

### 8.4 LBR ENHANCEMENTS

Next generation PMU introduces additional enhancements to Last Branch Records (LBRs) with details provided in the sub-sections that follow.

#### 8.4.1 LBR Event Logging

LBR Event Logging provides a means to log PMU event data in LBRs. This event data can be used to provide some causality information for the Cycle Time metadata currently recorded in the LBRs' IA32_LBR_x_INFO.CYC_CNT field (also known as Timed LBR).

When a programmable counter is enabled for a precise event and LBR is enabled, setting EN_LBR_LOG (bit 35) in the associated IA32_PERFEVTSELx MSR enables occurrences of the chosen event to be additionally logged in a new IA32_LBR_INFO.PMCx_CNT field. This two-bit field represents the number of occurrences of the event since retirement of the operation that last recorded an LBR entry, saturating at a value of 3. For example, this field is called PMC0_CNT at bits 33:32 of the IA32_LBR_x_INFO MSR for programmable counter 0. The same bits in the IA32_LER_x_INFO MSRs continue to be reserved.

If the event chosen in the IA32_PERFEVTSELx is MSR not precise, no counts will be logged in LBRs. The events that are precise on a given platform can be found in the online event list: [https://perfmon-events.intel.com/](https://perfmon-events.intel.com/).

When using LBR Event Logging, software should keep consistent CPL filtering settings between LBR and PerfMon. Keeping the OS/USR bits in the IA32_LBR_CTL MSR and in the IA32_PERFEVTSELx MSR consistent ensures that only events that occur in one or more chosen modes are logged. Similarly, software should keep FREEZE_LBRS_ON_PMI and FREEZE_PERFMON_ON_PMI in the IA32_DEBUGCTL MSR consistent. Other counter filtering in the IA32_PERFEVTSELx MSRs (e.g., INV, CMASK, EDGE, and IN_TX) should be cleared; otherwise the behavior and PMCx_CNT values are undefined.

Per-counter support for LBR Event Logging is indicated by the “Event Logging Supported” bitmap in CPUID.(EAX=01CH, ECX=0).ECX[19:16].
8.5 PERFMON MSRS ALIASING

Architectural performance monitoring version 6 supports a new range for counters' MSRs in the 19xxH address range.\(^1\)

All legacy and new counters, those enumerated in CPUID.(EAX=23H, ECX=01H), will be supported in a new address range. Moving forward, newer counters may be supported in the new address range, but not in the legacy address range. Additionally, MSRs in the new address range will take the default name, while MSRs in the legacy address range will have a "_LEGACY" suffix in their names.

For programmable counters, the IA32_A_PMCx MSR holds the counter value with full-width write support.\(^2\) The MSR address is 1900H + 4 * x. For example, the IA32_A_PMC1 MSR has MSR address 1904H. The aliased register for legacy counters is in MSR address 4C1H + x and is renamed to IA32_A_PMCx_LEGACY. The IA32_PERFEVTSELx MSR is the Performance Event Select Register at address 1901H + 4 * x. For example, IA32_PERFEVTSEL1 has MSR address 1905H. The aliased register for legacy counters is in MSR address 186H + x and is renamed to IA32_PERFEVTSELx_LEGACY.

For fixed-function counters, the IA32_FIXED_CTRx MSR holds the counter value. The MSR address is 1980H + 4 * x. For example, the IA32_FIXED_CTR1 MSR has MSR address 1984H. The aliased register for legacy counters is in MSR address 309H + x and is renamed to IA32_FIXED_CTRx_LEGACY.

The available programmable and fixed-function counters are reported by CPUID.(EAX=23H, ECX=01H):EAX and CPUID.(EAX=23H, ECX=01H):EBX, respectively.

---

1. This feature is available in a subset of processors with a CPUID signature value of DisplayFamily_DisplayModel 06_C5H or 06_C6H (though they report architectural performance monitoring version 5).
2. Note that the IA32_PMCx MSRs may only be supported in the legacy address range.
This chapter describes a new feature called **linear address space separation (LASS)**.

### 9.1 INTRODUCTION

Chapter 4 of the Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A describes **paging**, which is the process of translating linear addresses to physical addresses and determining, for each translation, the linear address’s **access rights**; these determine what accesses to a linear address are allowed.

Every access to a linear address is either a **supervisor-mode access** or a **user-mode access**. A linear address’s access rights include an indication of whether address is a **supervisor-mode address** or a **user-mode address**. Paging prevents user-mode accesses to supervisor-mode addresses; in addition, there are features that can prevent supervisor-mode accesses to user-mode addresses. (These features are supervisor-mode execution prevention — SMEP — and supervisor-mode access prevention — SMAP.) In most cases, the blocked accesses cause page-fault exceptions (#PF); for some cases (e.g., speculative accesses), the accesses are dropped without fault.

With these mode-based protections, paging can prevent malicious software from directly reading or writing memory inappropriately. To enforce these protections, the processor must traverse the hierarchy of paging structures in memory. Unprivileged software can use timing information resulting from this traversal to determine details about the paging structures, and these details may be used to determine the layout of supervisor memory.

Linear-address space separation (LASS) is an independent mechanism that enforces the same mode-based protections as paging but without traversing the paging structures. Because the protections enforced by LASS are applied before paging, “probes” by malicious software will provide no paging-based timing information.

LASS is based on a linear-address organization established by many operating systems: all linear addresses whose most significant bit is 0 (“low” or “positive” addresses) are user-mode addresses, while all linear addresses whose most significant bit is 1 (“high” or “negative” addresses) are supervisor-mode addresses. An operating system should enable LASS only if it uses this organization of linear addresses.

### 9.2 ENUMERATION AND ENABLING

Support for LASS is enumerated with CPUID.(EAX=07H.ECX=1):EAX.LASS[bit 6].

If a processor enumerates CPUID.(EAX=07H.ECX=1):EAX.LASS[bit 6] as 1, software can set CR4.LASS[bit 27]. Setting CR4.LASS to 1 enables LASS in IA-32e mode (when IA32_EFER.LMA = 1). LASS is not used in legacy mode, even if CR4.LASS = 1.

### 9.3 OPERATION OF LINEAR-ADDRESS SPACE SEPARATION

This section describes the operation of linear-address space separation (LASS). The discussion in this section applies only if IA32_EFER.LMA = CR4.LASS = 1. (If either of those control bits is zero, LASS does not apply.)

As indicated in Section 9.1, LASS enforces mode-based protections similar to those enforced by paging. Violations of these protections are called **LASS violations**. The processor will consult neither the paging structures nor the TLBs for an access that causes a LASS violation.

Like paging, LASS violations typically result in faults. Instead of page faults (#PF), an access causing a LASS violation results in the same fault that would occur if the access used an address that was not canonical relative to the current paging mode. In most cases, this is a general protection exception (#GP); for stack accesses (those due to stack-oriented instructions, as well as accesses that implicitly or explicitly use the SS segment register), it would be a stack fault (#SS).
Some accesses do not cause faults when they would violate the mode-based protections established by paging. These include prefetches (e.g., those resulting from execution of one of the PREFETCHh instructions), executions of the CLDEMOTE instruction, and accesses resulting from the speculative fetch or execution of an instruction. Such an access may cause a LASS violation; if it does, the access is not performed but no fault occurs. (When such an access would violate the mode-based protections of paging, the access is not performed but no page fault occurs.) In 64-bit mode, LASS violations have priority just below that of canonicality violations; in compatibility mode, they have priority just below that of segment-limit violations.

The remainder of this section describes how LASS applies to different types of accesses to linear addresses. Chapter 4, “Paging,” of the Intel® 64 and IA-32 Architectures Software Developer’s Manual, Volume 3A provides full definitions of these access types. The sections below discuss specific LASS violations based on bit 63 of a linear address. For a linear address with only 32 bits (or 16 bits), the processor treats bit 63 as if it were 0.

### 9.3.1 Data Accesses

A linear-address access is a **data access** if it is not for the fetch of an instruction. Such an access is a **user-mode access** if CPL = 3 and the access is not one that implicitly accesses a system data structure (e.g., the global descriptor table); it is a **supervisor-mode access** if CPL < 3 or if it implicitly accesses a system data structure.\(^1\)

A user-mode data access causes a LASS violation if it would access a linear address of which bit 63 is 1. It is expected that the operating system will configure paging so that any such address is a supervisor-mode address.

A supervisor-mode data access may cause a LASS violation if it would access a linear address of which bit 63 is 0. It is expected that the operating system will configure paging so that any such address is a user-mode address.

A supervisor-mode data access causes a LASS violation only if supervisor-mode access protection is enabled (because CR4.SMAP = 1) and either RFLAGS.AC = 0 or the access implicitly accesses a system data structure.

### 9.3.2 Instruction Fetches

Instruction fetches are always performed with linear addresses. An instruction fetch is **user-mode** if CPL = 3 and is supervisor mode if CPL < 3.

A user-mode instruction fetch causes a LASS violation if it would fetch an instruction using a linear address of which bit 63 is 1.

A **supervisor-mode** instruction fetch causes a LASS violation if it would accesses a linear address of which bit 63 is 0.

(Paging blocks supervisor-mode instruction fetches from user-mode linear addresses only if supervisor-mode execution protection has been enabled by setting CR4.SMEP to 1. Such instructions fetches cause LASS violations regardless of the setting of CR4.SMEP.)

It was noted earlier that LASS violations produce the same faults as canonicality violations and with a similar priority. LASS violations differ from canonicality violations in particular way as regards instruction flow. An instruction that loads RIP (a branch instruction) causes a general-protection exception (#GP) as a fault if it would load RIP with a value that is not canonical relative to the current paging mode; RIP is not updated, and the fault is reported on the branch instruction. In contrast, branch instructions do not check the target RIP for LASS violations, and thus LASS does not prevent branch instructions from completing. Fetch of the next instruction (at the target RIP) may cause a LASS violation and a #GP. In that case, the fault is reported on the branch target, not the branch instruction.

---

\(^1\) The WRUSS instruction is an exception; although it can be executed only if CPL = 0, the processor treats its shadow-stack accesses as user accesses.
10.1 INTRODUCTION

Remote Atomic Operations (RAO) are a set of instructions to improve synchronization performance. RAO is especially useful in multiprocessor applications that have a set of characteristics commonly found together:

- A need to update, i.e., read and modify, one or more variables atomically, e.g., because multiple processors may attempt to update the same variable simultaneously.
- Updates are not expected to be interleaved with other reads or writes of the variables.
- The order in which the updates happen is unimportant.

One example of this scenario is a multiprocessor histogram computation, where multiple processors cooperate to compute a shared histogram, which is then used in the next phase of computation. This is described in more detail in Section 10.8.1.

RAO instructions aim to provide high performance in this scenario by:

- Atomically updating memory without returning any information to the processor itself.
- Relaxing the ordering of RAO instructions with respect to other updates or writes to the variables.

RAO instructions are defined such that, unlike conventional atomics (e.g., LOCK ADD), their operations may be performed closer to memory, such as at a shared cache or memory controller. Performing operations closer to memory reduces or even eliminates movement of data between memory and the processor executing the instruction. They also have weaker ordering guarantees than conventional atomics. This facilitates execution closer to memory, and can also lead to reduced stalls in the processor pipeline. These properties mean that using RAO instead of conventional atomics may provide a significant performance boost for the scenario outlined above.

10.2 INSTRUCTIONS

The current set of RAO instructions can be found in Chapter 2, “Instruction Set Reference, A-Z.” These instructions include integer addition and bitwise AND, OR, and XOR. These operations may be performed on 32-bit (doubleword) or 64-bit (quadword) data elements. The destination, which is also one of the inputs, is always a location in memory. The other input is a general-purpose register, ry, in Table 10-1. The instructions do not change any registers or flags.

<table>

</tr>
</tbody>
</table>

10.3 ALIGNMENT REQUIREMENTS

The memory location updated by an RAO instruction must be naturally aligned. That is, a doubleword update must be four-byte aligned and a quadword update must be eight-byte aligned. This facilitates implementations closer to memory; otherwise, a single update may straddle a cache line boundary.
10.4 MEMORY ORDERING

RAO instructions have weaker memory ordering guarantees than conventional atomic instructions. Thus, other instructions are not ordered with respect to RAO instructions as they are with conventional atomics.

More specifically, the memory operations from RAO instructions follow the Write Combining (WC) memory protocol. From software's point of view, they behave similarly to non-temporal stores. Unlike non-temporal stores, RAO instructions update a memory location, i.e., use the value in that location as an input, rather than overwrite the current contents. Another critical difference is that with RAO, the memory location may be cached upon completion of the instruction.

RAO instructions are not reordered with other memory accesses to the same memory location. That is, reads, writes, and RAO instructions to the same location by the same processor will execute in program order. However, RAO instructions may be reordered with certain memory accesses to other memory locations. In particular, RAO instructions may be reordered with writes or RAO instructions to other memory locations. This means, for example, that if a processor executes a set of RAO instructions to a set of distinct addresses, those instructions may appear to update memory in any order.

If a stronger ordering is required, software should use a fencing operation such as those implemented by the LFENCE, SFENCE, and MFENCE instructions. However, note that RAO instructions are not ordered with respect to younger LFENCE instructions since they do not load data from memory into the processor.

10.5 MEMORY TYPE

RAO instructions are restricted to operating on Write Back (WB) memory. Other memory types place restrictions on the writing of and/or cacheability of data, which conflicts with RAO instructions' ability to cache data. Use of an RAO instruction to access non-WB memory results in a general-protection exception (#GP).

10.6 WRITE COMBINING BEHAVIOR

RAO implementations that execute updates closer to memory require interconnect traffic between a processor and the memory subsystem. To reduce such traffic, and increase the throughput of RAO operations, implementations may combine multiple RAO memory operations before execution. This is similar to how multiple writes via a WC protocol may combine before going to memory.

Implementations that combine RAO instructions take advantage of spatial locality, i.e., that a cache line contains multiple data elements, and that separate instructions may update distinct elements in a given cache line. For example, a first RAO instruction may update the first element in a cache line, and a second RAO instruction may update the third element.

Implementations may have restrictions on combining operations. For example, they may only be able to combine operations doing the same type of update (e.g., addition) and/or the same data element size.

Operations to the same cache line that are not combined must be serialized, and this could hurt performance. For example, an operation to a given cache line may need to complete before a second operation to that cache line may begin; otherwise, the memory system could have multiple concurrent accesses from the same processor to the same cache line, and some implementations do not support this.

10.7 PERFORMANCE EXPECTATIONS

RAO instructions are expected to provide higher performance than conventional atomics under certain conditions. The actual performance depends on both the implementation and the data access pattern for the memory location (at the cache line granularity) updated with RAO instructions.
10.7.1 Interaction Between RAO and Other Accesses

As discussed in Section 10.4, weak ordering allows RAO instructions to be reordered with respect to other memory operations. This is a key difference from conventional atomics, which follow strong memory ordering, and can allow a processor to execute RAO instructions with higher throughput. However, only certain reordering is allowed. If a fence is used to enforce stronger ordering, or if a processor interleaves RAO updates with reads of the same memory location, for example, this may result in serialized accesses, and hurt performance. If software performs an RAO update to a memory location, and soon after reads that memory location, then the read needs to wait for the update to complete. If the RAO is done close to memory, then the cache closest to the processor may not hold a copy of the cache line after the RAO instruction executes, and the read may need to access a cache farther away from the processor, or even go all the way to memory.

Mixing of RAO updates to a given memory location from one or more processors with non-RAO accesses to the same memory location can also reduce the benefits of RAO. Implementations that perform RAO updates close to memory can reduce data movement between a series of RAO updates to the same location. However, a non-RAO access may cause a processor to cache the data close to itself; a subsequent RAO instruction from another processor may require the line to be moved to a lower level of the cache hierarchy. Therefore, interleaving RAO and non-RAO accesses to a given memory location can reduce or eliminate the data movement and/or performance benefits of RAO.

10.7.2 Updates of Contended Data

Contended data is defined as data for which the memory system has memory accesses from multiple processors in-flight simultaneously. That is, for contended data, the memory system is at some point in time handling at least two accesses from different processors. Contended read-only data does not present a fundamental performance problem, but if at least one of the contending processors attempts to write the data, e.g., perform an update on it, the writer needs exclusive access to the data. Gaining exclusive access can be costly, in terms of latency and traffic; in a system with caches, hardware must invalidate all other copies of the data to provide a processor exclusive access.

For software performing a set of contended updates to a memory location with conventional atomic instructions, data may “ping-pong” between processors. As each processor executes its update, it will obtain exclusive access to the data, perform its update, and then have to send its new version of the data to the next processor wanting to update it. The time to pass data from one processor to another, and the time that a processor takes to perform its atomic update, limits the throughput in this scenario.

In contrast, if software uses RAO for such contended updates, and if the implementation performs the updates in a central location such as a shared cache or at the memory controller, then this bottleneck is alleviated. In such a scenario, each update will not have to fetch the current contents of the memory location or invalidate any other copies of the data because the only valid copy is already at the hardware performing the update. The only fundamental limit to the throughput in this case is the time taken for each update. Therefore, we may expect that for updates to contended lines, throughput is much higher with RAO. Further, reducing data movement means reducing traffic between processors and memory. This may improve the performance of other memory accesses.

10.7.3 Updates of Uncontended Data

In contrast to contended data, uncontended data is data that is accessed by only a single processor or by multiple processors, but far enough apart in time that at most a single memory access is executed at a time.

For uncontended data accessed by multiple processors, most of the above discussion about contended data still applies. However, the frequency of updates is by definition lower for uncontended data. Therefore, the performance benefits of RAO are expected to be lower in this situation.

For data accessed by only a single processor, data movement between processors is not an issue, and conventional atomics can take advantage of the processor’s caches. Performance may still be impacted by the strong ordering of conventional atomics; memory accesses to other memory locations may not be reordered with these instructions. If software uses RAO instructions instead, the weaker ordering may provide some performance benefits. However, if an implementation performs RAO updates closer to memory, it may not take advantage of all of the processor’s caches, and may even require removing the data from some of those caches. This could lead to an increase in data movement, and potentially lower performance. Of course, if software is aware that only a single processor will access the data, then it does not need to use atomic updates, but it may not always be so aware.
10.8 EXAMPLES

10.8.1 Histogram

Histogram is a common computational pattern, including in multiprocessor programming, but achieving an efficient parallel implementation can be tricky. In a conventional histogram computation, software sweeps over a set of input values; it maps each input value to a histogram bin, and increments that bin.

Common multiprocessor histogram implementations partition the inputs across the processors, so each processor works on a subset of the inputs. Straightforward implementations have each processor directly update the shared histogram. To ensure correctness, since multiple processors may attempt updates to the same histogram bin simultaneously, the updates must use atomics. As described above, using conventional atomics can be expensive, especially when we have highly contended cache lines in the histogram. That may occur for small histograms or for histograms where many inputs map to a small number of histogram bins.

A common alternative approach uses a technique called privatization, where each processor gets its own "local" histogram; as each processor works on its subset of the inputs, it updates its local histogram. As a final "extra" step, software must accumulate the local histograms into the globally shared histogram, a step called a reduction. This reduction step is where processors synchronize and communicate; using it allows the computation of local histograms to be embarrassingly parallel and require no atomics or inter-processor communication, and can often lead to good performance. However, privatization has downsides:

- The reduction step can take a lot of time if the histogram has many bins.
- The time for a reduction is relatively constant regardless of the number of processors. As the number of processors grows, therefore, the fraction of time spent on the reduction tends to grow.
- The local histograms require extra memory, and that memory footprint grows with the number of processors.
- The reduction is an "extra" step that complicates the software.

With RAO, software can use the simpler multiprocessor algorithm and achieve reliably good performance. The following pseudo-code lists a RAO-based histogram implementation.

```c
int *histogram; // "histogram" is a global histogram array

// in each processor:
double *data; // "data" is a per-processor array, holding a subset of all inputs
data = get_data(); // populate "data" values

for (size_t i = 0; i < data_size; ++i) {
    int bin = map(data[i]); // map data[i] to a histogram bin
    _aadd(&histogram[bin], 1); // RAO AADD instruction
}
```

The above code can provide good performance under various scenarios, i.e., sizes of histograms and biases in which histogram bins are updated. RAO avoids data "ping-ponging" between processors, even under high contention. Further, the weak ordering of RAO allows a series of AADD instructions to overlap with each other in the pipeline, and thus provide for instruction level parallelism.

In addition to the performance benefits, the RAO code is simple and is thus easier to maintain.

While we specifically show and discuss histogram above, this computation pattern is very common, e.g., software packet processing workloads exhibit this in how they track statistics of the packets. Other algorithms exhibiting this pattern should similarly see benefits from RAO.

10.8.2 Interrupt/Event Handler

An interrupt/event handler, running either in a dedicated thread or preemptively in a specific processor, notifies a set of receivers (e.g., all processors or threads in a waiting list) of the occurrence of an event by atomically setting flags in the receivers' specific data fields. The example below shows how this may be done with RAO instructions.
// One processor sets event bits to notify other processors:
void handle_event(event_t *e) {
    uint32_t event_bits = process_event(e);
    for (int i = 0; i < num_of_receivers; ++i) {
        core_t *core = receivers[i];
        _aor(&core->flags, event_bits); // RAO AOR instruction
        if (some_condition) {
            _aor(&core->extra_flags, event_bits); // combining of RAO could occur
        }                // if "extra_flags" and "flags" are in the same cache line
    }
    _mm_sfence();  // ensure event_bits are visible before leaving the handler
}

// In other processors:
if (my_core->flags & SOME_EVENT) {
    …… // react to the occurrence of SOME_EVENT
    clear_bits(&my_core->flags, SOME_EVENT);
}

With conventional atomics (e.g., LOCK OR), a significant portion of execution time of handle_event would be spent accessing core->flags (line 5) and core->extra_flags (line 7). It is likely that when handle_event begins, the two fields are in another processor's cache, e.g., if that processor updated some bits in the fields. Therefore, the data would need to migrate to the cache of the processor executing handle_event.

In contrast, for the above code example, for RAO implementations that perform updates close to memory, the RAO AOR instruction should reduce data movement of core->flags and core->extra_flags and thus result in a lower execution latency. Further, when other processors later access these fields (lines 12-15), they will also benefit from a lower latency due to reduced data movement, since they may get the data from a more central location.

Also note that since the order of notifications does not matter in this case, the function further takes advantage of RAO's weak ordering, allowing multiple RAO AOR instructions to be executed concurrently. It does, however, include a memory fence at the end (line 10), to ensure that all updates are visible to all processors before leaving the handler.
11.1 INTRODUCTION

Total Storage Encryption (TSE) is an architecture that allows encryption of storage at high speed. TSE provides the following capabilities:

- Protection (confidentiality) of data at rest in storage.
- NIST Standard AES-XTS Encryption.
- A mechanism for software to configure hardware keys (which are not software visible) or software keys.
- A consistent key interface to the crypto engine.

11.1.1 Key Programming Overview

Keys for TSE can either be programmed directly in plain text or through wrapped Binary Large Objects (BLOBs).

- Direct programming: Software programs keys after reset to the TSE engine using a structure in memory. Keys may be exposed in memory.
- Wrapped BLOB programming: Wrapped-key BLOBs are generated once at provisioning time, persist across boots, and are used directly to program the TSE engine without unwrapping/recovering keys in software.

11.1.1.1 Key Wrapping Support: PBNDKB

Platform Bind Key BLOB (PBNDKB) allows software to wrap secret information with a platform-specific wrapping key and bind it to the TSE engine.

11.1.2 Unwrapping and Hardware Key Programming Support: PCONFIG

The PCONFIG instruction allows software to program keys to the TSE engine either directly from memory or using PBNDKB-generated wrapped BLOBs.

The PCONFIG instruction is also used to program the MKTME engine. For additional details on the PCONFIG instruction, see Chapter 2 of this document.

11.2 ENUMERATION

CPUID enumerates the existence of the IA32_TSE_CAPABILITY MSR and the PBNDKB instruction.

The IA32_TSE_CAPABILITY MSR enumerates supported cryptographic algorithms and keys.

11.2.1 CPUID Detection

If CPUID.(EAX=07H, ECX=1):EBX.TSE[bit 1] = 1, the processor supports the IA32_TSE_CAPABILITY MSR and the PBNDKB instruction.

11.2.1.1 PCONFIG CPUID Leaf Extended to Support Total Storage Encryption

TSE is assigned a PCONFIG target identifier. The current PCONFIG target identifiers are as follows:

- 0: Invalid Target ID
- 1: MKTME
2: TSE
If TSE is supported on the platform, CPUID.PCONFIG_LEAF will enumerate TSE as a supported target in sub-leaf 0, ECX=TSE:
• TSE_KEY_PROGRAM leaf is available when TSE is enumerated by PCONFIG as a target.
• TSE_KEY_PROGRAM_WRAPPED is available when TSE is enumerated by PCONFIG as a target.

11.2.2 Total Storage Encryption Capability MSR
The TSE_CAPABILITY MSR (9F1H) enumerates the supported capabilities of TSE. It has the fields shown in Table 11-1.

<table>
<thead>
<tr>
<th>Bit</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>15:0</td>
<td>Supported encryption algorithms (see below).</td>
</tr>
<tr>
<td>23:16</td>
<td>TSE Engine Key Sources Supported.</td>
</tr>
<tr>
<td>35:24</td>
<td>Reserved.</td>
</tr>
<tr>
<td>50:36</td>
<td>TSE_MAX_KEYS (Indicates the maximum number of keys that are available).</td>
</tr>
<tr>
<td>63:51</td>
<td>Reserved.</td>
</tr>
</tbody>
</table>

Bits 15:0 enumerate, as a bitmap, the encryption algorithms that are supported. As of this writing, the only supported algorithm is 256-bit AES-XTS, which is enumerated by setting bit 0.

11.3 VMX SUPPORT

11.3.1 Changes to VMCS Fields
A new execution control called “enable PBNDKB” is added to support TSE in bit 9 of the tertiary processor-based execution controls field of the VMCS. If this control is zero, then any execution of the PBNDKB instruction causes an invalid-opcode exception (#UD).

11.3.2 Changes to VMX Capability MSRs
Support for “enabled PBNDKB” is indicated by bit 9 of the IA32_VMX_PROCBASED_CTLS3 MSR (index 492H).

11.3.3 Changes to VM Entry
If bit 9 is clear in the IA32_VMX_PROCBASED_CTLS3 MSR, then VM entry fails if “enable PBNDKB” and the “activate tertiary controls” primary processor-based VM-execution control are both 1.

11.4 INSTRUCTION SET
See Chapter 2 for details on the PBNDKB instruction, as well as information on updates to the PCONFIG instruction.
